Contents in Brief

1 Introduction to Chemistry 1
1.1 The Scope of Chemistry 2
1.2 Chemistry and You 6
1.3 Thinking Like a Scientist 14
1.4 Problem Solving in Chemistry 22

2 Matter and Change 32
2.1 Properties of Matter 34
2.2 Mixtures 38
2.3 Elements and Compounds 42
2.4 Chemical Reactions 48

3 Scientific Measurement 60
3.1 Using and Expressing Measurements . . 62
3.2 Units of Measurement 74
3.3 Solving Conversion Problems 84

4 Atomic Structure 100
4.1 Defining the Atom 102
4.2 Structure of the Nuclear Atom 105
4.3 Distinguishing Among Atoms 112

5 Electrons in Atoms 126
5.1 Revising the Atomic Model 128
5.2 Electron Arrangement in Atoms 134
5.3 Atomic Emission Spectra and the Quantum Mechanical Model 138

6 The Periodic Table 158
6.1 Organizing the Elements 160
6.2 Classifying the Elements 167
6.3 Periodic Trends 174

7 Ionic and Metallic Bonding 192
7.1 Ions 194
7.2 Ionic Bonds and Ionic Compounds . . . 201
7.3 Bonding in Metals 209

8 Covalent Bonding 220
8.1 Molecular Compounds 222
8.2 The Nature of Covalent Bonding 226
8.3 Bonding Theories 240
8.4 Polar Bonds and Molecules 247

9 Chemical Names and Formulas 262
9.1 Naming Ions 264
9.2 Naming and Writing Formulas for Ionic Compounds 271
9.3 Naming and Writing Formulas for Molecular Compounds 280
9.4 Naming and Writing Formulas for Acids and Bases 285
9.5 The Laws Governing How Compounds Form 289

10 Chemical Quantities 304
10.1 The Mole: A Measurement of Matter 306
10.2 Mole–Mass and Mole–Volume Relationships 317
10.3 Percent Composition and Chemical Formulas 325

11 Chemical Reactions 344
11.1 Describing Chemical Reactions 346
11.2 Types of Chemical Reactions 356
11.3 Reactions in Aqueous Solution 369

12 Stoichiometry 382
12.1 The Arithmetic of Equations 384
12.2 Chemical Calculations 390
12.3 Limiting Reagent and Percent Yield . . . 400

13 States of Matter 418
13.1 The Nature of Gases 420
13.2 The Nature of Liquids 425
13.3 The Nature of Solids 431
13.4 Changes of State 436

14 The Behavior of Gases 448
14.1 Properties of Gases 450
14.2 The Gas Laws 456
14.3 Ideal Gases 464
14.4 Gases: Mixtures and Movements 469

15 Water and Aqueous Systems 486
15.1 Water and Its Properties 488
15.2 Homogeneous Aqueous Systems 494
15.3 Heterogeneous Aqueous Systems 504

16 Solutions 516
16.1 Properties of Solutions 518
16.2 Concentrations of Solutions 525
16.3 Colligative Properties of Solutions 534
16.4 Calculations Involving Colligative Properties 538

17 Thermochemistry 554
17.1 The Flow of Energy 556
17.2 Measuring and Expressing Enthalpy Changes 562
17.3 Heat in Changes of State 569
17.4 Calculating Heats of Reaction 578

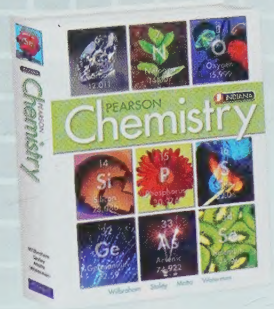
18 Reaction Rates and Equilibrium 592
18.1 Rates of Reaction 594
18.2 The Progress of Chemical Reactions . . 604
18.3 Reversible Reactions and Equilibrium . . 609
18.4 Solubility Equilibrium 621
18.5 Free Energy and Entropy 627

19 Acids, Bases, and Salts 644
19.1 Acid-Base Theories 646
19.2 Hydrogen Ions and Acidity 653
19.3 Strengths of Acids and Bases 664
19.4 Neutralization Reactions 672
19.5 Salts in Solution 676

20 Oxidation-Reduction Reactions 690
20.1 The Meaning of Oxidation and Reduction 692
20.2 Oxidation Numbers 701
20.3 Describing Redox Equations 707

21 Electrochemistry 726
21.1 Electrochemical Cells 728
21.2 Half-Cells and Cell Potentials 737
21.3 Electrolytic Cells 745

22 Hydrocarbon Compounds 760
22.1 Hydrocarbons 762
22.2 Unsaturated Hydrocarbons 772
22.3 Isomers 775
22.4 Hydrocarbon Rings 779
22.5 Hydrocarbons from Earth's Crust 782



23 Functional Groups 796
23.1 Introduction to Functional Groups 798
23.2 Alcohols, Ethers, and Amines 804
23.3 Carbonyl Compounds 812
23.4 Polymers 822

24 The Chemistry of Life 836
24.1 A Basis for Life 838
24.2 Carbohydrates 841
24.3 Amino Acids and Their Polymers 844
24.4 Lipids 850
24.5 Nucleic Acids 854
24.6 Metabolism 862

25 Nuclear Chemistry 874
25.1 Nuclear Radiation 876
25.2 Nuclear Transformations 880
25.3 Fission and Fusion 888
25.4 Radiation in Your Life 894

Elements Handbook R2

Problem Bank R51

PEARSON Chemistry

INDIANA

"The integration of problem-solving support, technology, and real-world application in *Pearson Chemistry* is above and beyond any program I've seen in my years teaching."

– Mary Chuboff, Athens Academy

Pearson Chemistry for Indiana – All the Elements for Success

The *Pearson Chemistry for Indiana* program combines proven content with cutting-edge digital support and a variety of hands-on learning opportunities to help ensure success in your chemistry classroom. *Pearson Chemistry* provides tools to help you engage and motivate your students, as well as offers support for all the levels and types of learners in your classroom.

A Program Backed by Research

In developing *Pearson Chemistry for Indiana*, the use of research is a guiding, central construct. Research indicated key elements of a textbook program that ensure students' success: support for reading and mathematics in science, consistent opportunities for inquiry, and an ongoing assessment strand.

1 Exploratory Needs Assessment

(Quantitative and Qualitative)

Key research events include —

- Teacher interviews
- Classroom observations
- Mail surveys
- Reviews of educational research

2 Formative Prototype Development and Field Testing

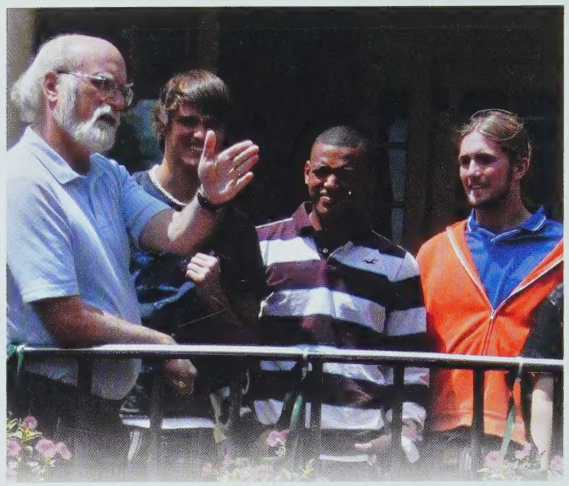
(Quantitative and Qualitative)

Key research events include —

- Field testing of prototypes
- Classroom observations
- Teacher reviews
- Supervisor reviews
- Educator advisory panel

3 Summative Validation Research

(Experimental and Quasi-Experimental Study Designs & Qualitative Research)



Key research events include —

- Pre-publication learner verification research
- Post-publication efficacy studies
- Classroom observations
- Effect size studies

Build a Framework for Learning with Understanding by Design

Understanding by Design® (UbD), developed by Grant Wiggins and Jay McTighe, offers a framework for creating understanding, not by accident or happenstance, but deliberately by design. UbD is a disciplined way of thinking about the design of curriculum, instruction, and assessment that moves teaching from covering the content to ensuring understanding. In the Teacher's Edition of *Pearson Chemistry for Indiana*, we've incorporated Understanding by Design principles into every lesson.

"The big-idea questions signal that education is not just about learning 'the answer' but about learning how to learn."

— Grant Wiggins, Ed.D., Harvard University

1 Plan for Understanding

The goal of teaching chemistry is not to teach students a bunch of facts about chemistry, but to develop a deeper understanding. Chemistry is the study of the composition of matter and the changes that matter undergoes. How do you help your students understand chemistry on this scale?

In *Pearson Chemistry for Indiana*, your students are introduced to Big Ideas, Essential Questions, and Key Questions in the Student Edition. The Teacher's Edition builds on these, providing questions to help students uncover a deeper understanding.

Each chapter is represented by one or more Big Ideas that can be explored using an Essential Question. Each lesson is also accompanied by Key Questions that are tied to the Essential Questions. If students can answer these questions, you know they have grasped important concepts in chemistry.

2 Set Assessment Goals

A critical aspect of any UbD lesson plan is thinking backwards from the desired goal of enduring understandings to what you will accept as evidence of those understandings. The following features of the Teacher's Edition will help you identify desired accomplishments and plan appropriate assessment goals.

- Performance Goals, Chapter Opener—highlights activities by which students can demonstrate a broader understanding of chemistry concepts.
- Evidence of Understanding, Lesson Opener—alternative assessments that help you determine if your students can make meaning from what they read in a lesson.
- Performance Tasks, Chapter Study Guide—suggestions for both a Summative and a Transfer Task to that ensure that students grasp chapter content.

UbD Understanding by Design

Students are building toward naming and writing formulas for compounds using their knowledge of atoms, ions, and bonding.

PERFORMANCE GOALS At the end of Chapter 9, students will be able to answer the essential questions by applying their knowledge of ions, ionic compounds, and molecular compounds. Students will also be able to name and write formulas for compounds.

ESSENTIAL QUESTIONS Read the essential questions aloud. **Ask** What is an ion? *(an atom or group of atoms that has a positive or negative charge)* **Ask** How is an ion different from a molecule? *(An ion has a charge, but a molecule is neutral.)*

3 Teach the Concepts

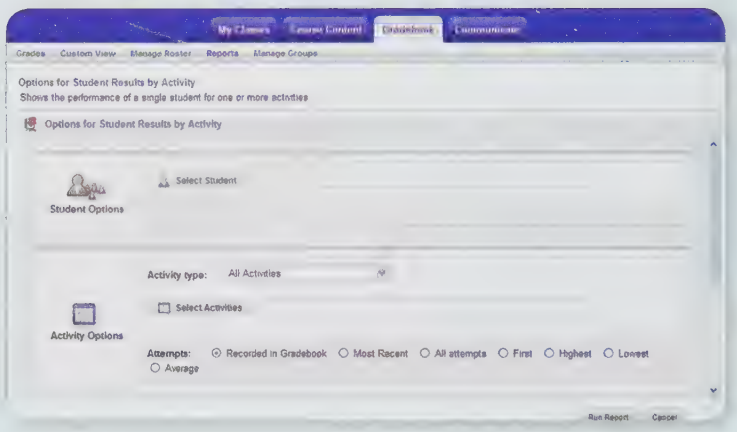
In addition to being goal-focused, a UbD lesson plan should include interim assessment tasks to assess students' progress through a lesson. The Teacher's Edition includes **Check for Understanding** boxes that can be used at a specific point in a lesson. These include a variety of informal assessment strategies—for example, follow-up probes, visual representations, question boxes, one-minute responses, and hand signals. Also included are suggestions for adjusting your instruction to address students' misunderstandings or misconceptions mid-lesson.

UbD Check for Understanding

The Essential Question **How can you determine the charges of monoatomic ions?**

Assess students' comprehension by asking them to show you how they use the groups in the periodic table to determine the charge on any given monatomic ion. Students should properly use the terms *cations* and *anions* in their explanation.

ADJUST INSTRUCTION If students are having trouble answering, provide them a clean copy of the periodic table. Instruct them to use colored pencils to color code the groups within the table to help them determine the charges. Direct students to revisit the text following the *Cations* and *Anions* subheads.



Integrate Technology in Your Chemistry Classroom

PearsonChem.com is the next generation of digital instruction, offering complete online Student and Teacher Editions, a comprehensive teacher center, digital lessons, interactive animations, simulations, and assessments in one place. Featuring the latest in digital instructional technology, **PearsonChem.com** integrates the key concepts from the text and brings them alive online.

Enhanced Classroom Instruction

- A sophisticated classroom management system allows you to organize your class reports and track student progress easily.
- Online Teacher Center contains assignable activities, homework, quizzes, and tests with automatic grading capabilities.

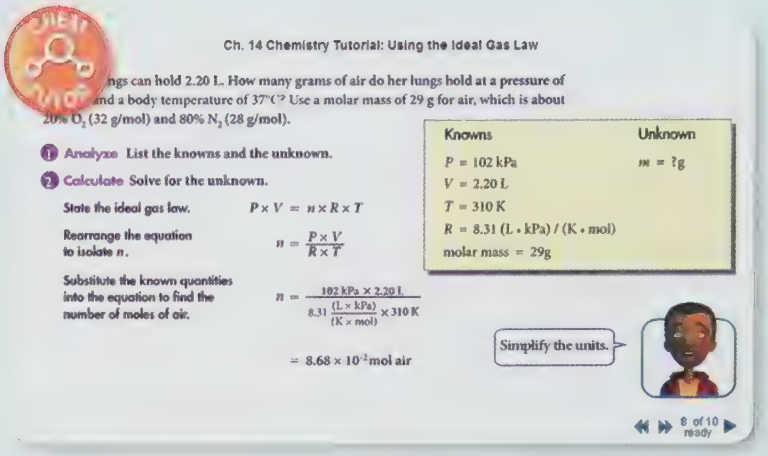
Flexible Tools to Customize Your Instruction

- Hundreds of editable labs in various formats (traditional, small-scale, probeware, lab practicals) allow you to choose the labs that best fit your teaching style.
- PowerPoint presentations provide you with pre-set lesson overview slides that you can use as is or change with the click of a button.
- Editable assessment resources let you pick the level and type of chapter or unit test that fits your classroom needs.
- Student Study worksheets in an editable format give you control over adding or changing anything you might want to in the Reading and Study Workbook.

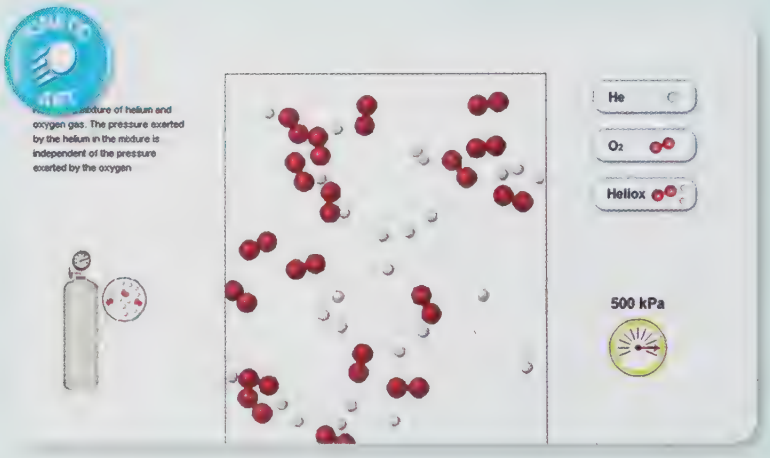
Integration of Chemistry and Technology

Each lesson opener directs you and your students to the online resources available. Go to the Online Student Edition with Audio.

Use Math Tutorial to review key math skills that apply to the chapter.



Get extra practice with Online Problem Sets.



See art from the textbook brought to life as interactive animations or simulations.

Review key chapter concepts in a real-world context with Concepts in Action.

Use Chem Tutorial to reinforce the problem-solving approach step by step.

Directed Virtual Lab demonstrations allow students to conduct labs with no safety issues and clean up at the click of a button.

Engage Your Students with Hands-On and Virtual Labs Experience

Inquiry and Active Learning

Inquiry is the heart and soul of science education, but what is it?

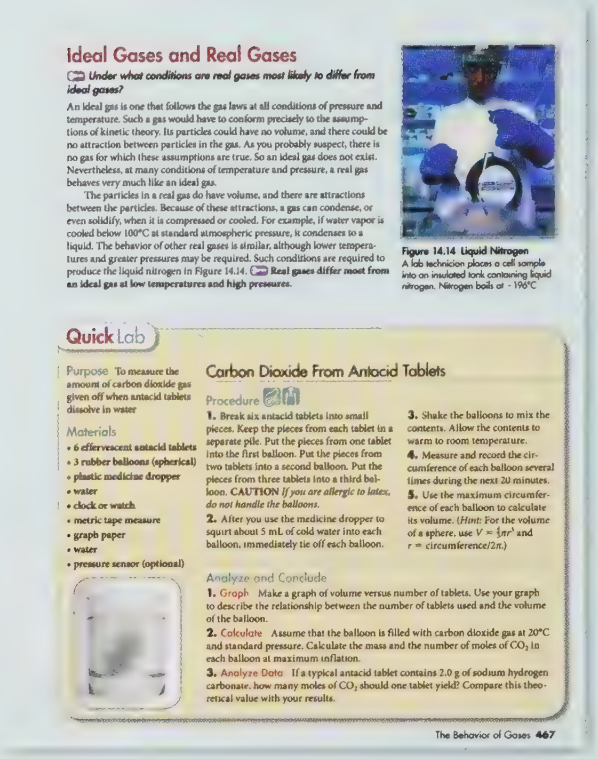
Defining Science Inquiry

Simply put, inquiry is the intellectual side of science. It's thinking like a scientist—being inquisitive, asking why, and searching for answers. The National Science Education Content Standards define inquiry as the process in which students begin with a question, design an investigation, gather evidence, formulate an answer to the original question, and communicate the investigative process and results. Since it's often difficult to accomplish all this in one class period, the standards also acknowledge that at times students need to practice only one or two inquiry components.

Inquiry in *Pearson Chemistry*

Pearson Chemistry offers the most opportunities to get students to think like scientists and enables students to enhance their understanding by participating in the discovery.

Pearson Chemistry encourages students to develop inquiry skills across the spectrum from teacher-guided to open-ended. Flexible lab options are included in every chapter, structured from directed to open-ended—providing the flexibility to address all types of learners and accommodate your class time and equipment requirements.



In the Student Edition

Quick Labs

Quick Labs provide students the opportunity to discover science with a variety of investigations through open-ended inquiry. These labs deepen student understanding of Key Concepts and Big Ideas.

Chapter Labs

Chapter-level Small-Scale Labs offer longer, more rigorous investigations that connect back to the Big Idea of the chapter. Each Small-Scale Lab includes extensions for further analysis and/or opportunities to design follow-up experiments.

Ideal Gases and Real Gases

Under what conditions are real gases most likely to differ from ideal gases?

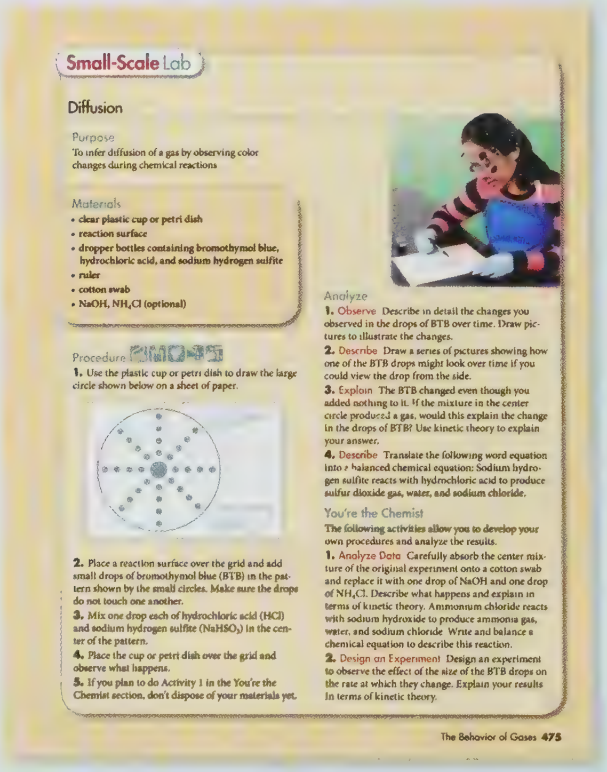
An ideal gas is one that follows the gas laws at all conditions of pressure and temperature. Such a gas would have to conform precisely to the assumptions of kinetic theory. Its particles could have no volume, and there could be no attraction between particles in the gas. As you probably suspect, there is no gas for which these assumptions are true. So an ideal gas does not exist. Nevertheless, at many conditions of temperature and pressure, a real gas behaves very much like an ideal gas.

The particles in a real gas do have volume, and there are attractions between the particles. Because of these attractions, a gas can condense, or even solidify, when it is compressed or cooled. For example, if water vapor is cooled below 100°C at standard atmospheric pressure, it condenses to a liquid. The behavior of other real gases is similar, although lower temperatures and greater pressures may be required. Such conditions are required to produce the liquid nitrogen in Figure 14.14. Real gases differ most from an ideal gas at low temperatures and high pressures.

Figure 14.14 Liquid Nitrogen
A lab technician places a cell sample into an insulated tank containing liquid nitrogen. Nitrogen boils at −196°C

Quick Lab

Carbon Dioxide From Antacid Tablets



Purpose To measure the amount of carbon dioxide gas given off when antacid tablets dissolve in water

Materials
- 6 effervescent antacid tablets
- 3 rubber balloons (spherical)
- plastic medicine dropper
- water
- clock or watch
- metric tape measure
- graph paper
- water
- pressure sensor (optional)

Procedure
1. Break six antacid tablets into small pieces. Keep the pieces from each tablet in a separate pile. Put the pieces from one tablet into the first balloon. Put the pieces from two tablets into a second balloon. Put the pieces from three tablets into a third balloon. CAUTION *If you are allergic to latex, do not handle the balloons.*
2. After you use the medicine dropper to squirt about 5 mL of cold water into each balloon, immediately tie off each balloon.
3. Shake the balloons to mix the contents. Allow the contents to warm to room temperature.
4. Measure and record the circumference of each balloon several times during the next 20 minutes.
5. Use the maximum circumference of each balloon to calculate its volume. (*Hint:* For the volume of a sphere, use $V = \frac{4}{3}\pi r^3$ and $r = \text{circumference}/2\pi$.)

Analyze and Conclude
1. Graph Make a graph of volume versus number of tablets. Use your graph to describe the relationship between the number of tablets used and the volume of the balloon.
2. Calculate Assume that the balloon is filled with carbon dioxide gas at 20°C and standard pressure. Calculate the mass and the number of moles of CO_2 in each balloon at maximum inflation.
3. Analyze Data If a typical antacid tablet contains 2.0 g of sodium hydrogen carbonate, how many moles of CO_2 should one tablet yield? Compare this theoretical value with your results.

The Behavior of Gases 467

Small-Scale Lab

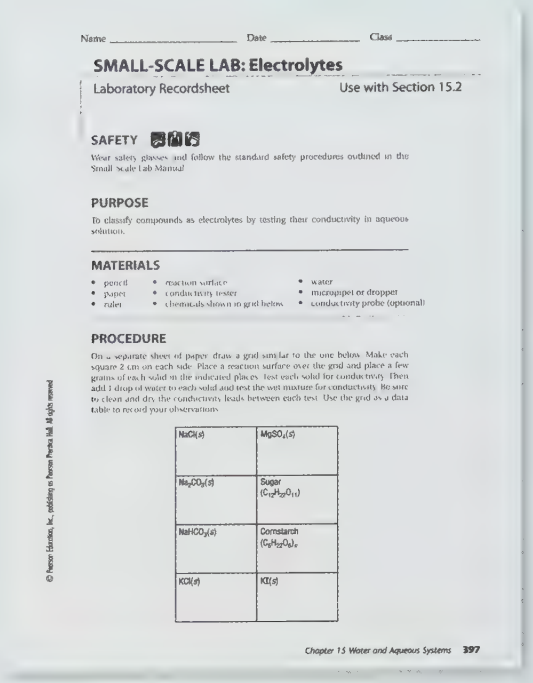
Diffusion

Purpose
To infer diffusion of a gas by observing color changes during chemical reactions

Materials
- clear plastic cup or petri dish
- reaction surface
- dropper bottles containing bromothymol blue, hydrochloric acid, and sodium hydrogen sulfite
- ruler
- cotton swab
- NaOH, NH_4Cl (optional)

Procedure
1. Use the plastic cup or petri dish to draw the large circle shown below on a sheet of paper.
2. Place a reaction surface over the grid and add small drops of bromothymol blue (BTB) in the pattern shown by the small circles. Make sure the drops do not touch one another.
3. Mix one drop each of hydrochloric acid (HCl) and sodium hydrogen sulfite ($NaHSO_3$) in the center of the pattern.
4. Place the cup or petri dish over the grid and observe what happens.
5. If you plan to do Activity 1 in the You're the Chemist section, don't dispose of your materials yet.

Analyze
1. Observe Describe in detail the changes you observed in the drops of BTB over time. Draw pictures to illustrate the changes.
2. Describe Draw a series of pictures showing how one of the BTB drops might look over time if you could view the drop from the side.
3. Explain The BTB changed even though you added nothing to it. If the mixture in the center circle produced a gas, would this explain the change in the drops of BTB? Use kinetic theory to explain your answer.
4. Describe Translate the following word equation into a balanced chemical equation: Sodium hydrogen sulfite reacts with hydrochloric acid to produce sulfur dioxide gas, water, and sodium chloride.



You're the Chemist
The following activities allow you to develop your own procedures and analyze the results.
1. Analyze Data Carefully absorb the center mixture of the original experiment onto a cotton swab and replace it with one drop of NaOH and one drop of NH_4Cl. Describe what happens and explain in terms of kinetic theory. Ammonium chloride reacts with sodium hydroxide to produce ammonia gas, water, and sodium chloride. Write and balance a chemical equation to describe this reaction.
2. Design an Experiment Design an experiment to observe the effect of the size of the BTB drops on the rate at which they change. Explain your results in terms of kinetic theory.

The Behavior of Gases 475

On PearsonChem.com

Online Editable Labs

A wealth of labs are available to you online in an editable format, which allows you to make the labs your own and tailor them to fit your needs. Labs available include traditional labs, small-scale labs, lab practicals, and probeware labs. *Pearson Chemistry*'s online lab program allows you the flexibility to select the labs that you want and make the necessary changes to fit your classroom needs.

Name _____ Date _____ Class _____

SMALL-SCALE LAB: Electrolytes

Laboratory Recordsheet — Use with Section 15.2

SAFETY

Wear safety glasses and follow the standard safety procedures outlined in the Small-Scale Lab Manual.

PURPOSE

To classify compounds as electrolytes by testing their conductivity in aqueous solution.

MATERIALS

- pencil
- paper
- ruler
- reaction surface
- conductivity tester
- chemicals shown in grid below
- water
- micropipet or dropper
- conductivity probe (optional)

PROCEDURE

On a separate sheet of paper, draw a grid similar to the one below. Make each square 2 cm on each side. Place a reaction surface over the grid and place a few grains of each solid in the indicated places. Test each solid for conductivity. Then add 1 drop of water to each solid and test the wet mixture for conductivity. Be sure to clean and dry the conductivity leads between each test. Use the grid as a data table to record your observations.

$NaCl(s)$	$MgSO_4(s)$
$Na_2CO_3(s)$	Sugar ($C_{12}H_{22}O_{11}$)
$NaHCO_3(s)$	Cornstarch ($(C_6H_{10}O_5)_x$)
$KCl(s)$	$KI(s)$

On CD-ROM

Virtual ChemLab

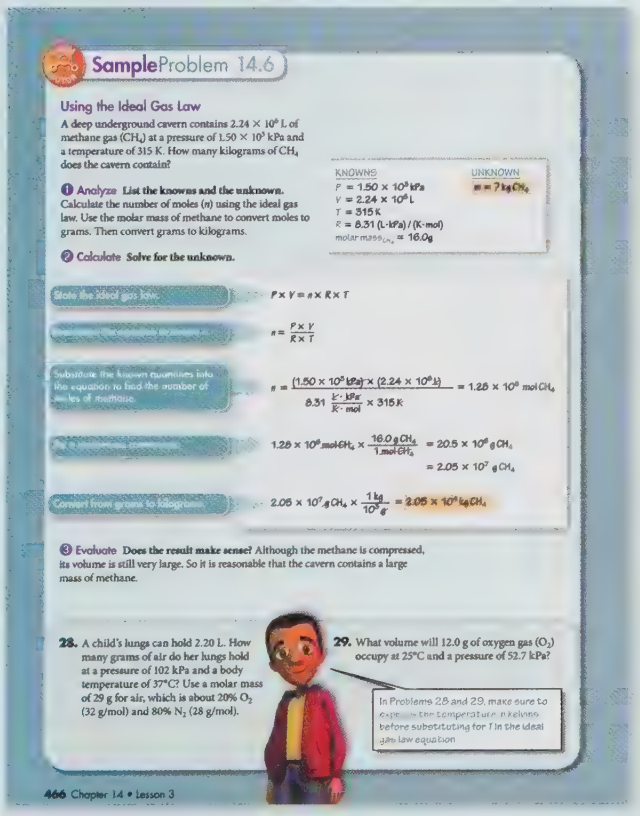
The Virtual ChemLab CD-ROM helps chemistry concepts come to life in a hands-on lab environment simulated on the computer screen, rendering safety and equipment needs obsolete. The Virtual ChemLab Workbook provides an additional 30 labs that are correlated to existing labs in the Student Edition and Laboratory Manual.

Virtual ChemLab offers a powerful lab simulation environment for performing investigations involving gas properties, calorimetry, titrations, qualitative analysis, and quantum chemistry.

A Fresh Approach to Problem-Solving and Math Support

Problem Solving in the Chemistry Curriculum

In chemistry, problem solving is an important set of skills that students must learn and then develop through practice. In *Pearson Chemistry for Indiana*, students are taught an approach to problem solving that applies to both numeric (quantitative) and conceptual (qualitative) problems. These same problem-solving skills can be used to solve relatively simple problems or complex problems whose solutions require multiple steps. As students practice and gain confidence in their abilities, they will be able to apply their problem-solving skills in new situations and trust that their answers make sense.



"By having the skills of understanding and utilizing problem solving at their disposal, students can approach brand new situations and trust that their results make sense."

– Dennis D. Staley,
Pearson Chemistry co-author

In the Student Edition

Stepped-out sample problems show your students how to go about solving chemistry problems with hints along the way.

Sample Problem 14.6

Using the Ideal Gas Law

A deep underground cavern contains 2.24×10^6 L of methane gas (CH_4) at a pressure of 1.50×10^3 kPa and a temperature of 315 K. How many kilograms of CH_4 does the cavern contain?

1 Analyze **List the knowns and the unknown.** Calculate the number of moles (n) using the ideal gas law. Use the molar mass of methane to convert moles to grams. Then convert grams to kilograms.

KNOWNS: $P = 1.50 \times 10^3$ kPa; $V = 2.24 \times 10^6$ L; $T = 315$ K; $R = 8.31$ (L·kPa)/(K·mol); molar mass$_{CH_4} = 16.0$ g

UNKNOWN: $m = ? \text{ kg } CH_4$

2 Calculate **Solve for the unknown.**

State the ideal gas law: $P \times V = n \times R \times T$

$n = \frac{P \times V}{R \times T}$

Substitute the known quantities into the equation to find the number of moles of methane: $n = \frac{(1.50 \times 10^3 \text{ kPa}) \times (2.24 \times 10^6 \text{ L})}{8.31 \frac{\text{L} \cdot \text{kPa}}{\text{K} \cdot \text{mol}} \times 315 \text{ K}} = 1.28 \times 10^6 \text{ mol } CH_4$

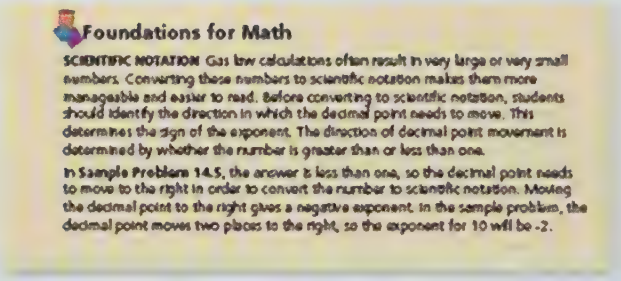
$1.28 \times 10^6 \text{ mol } CH_4 \times \frac{16.0 \text{ g } CH_4}{1 \text{ mol } CH_4} = 20.5 \times 10^6 \text{ g } CH_4$

$= 2.05 \times 10^7 \text{ g } CH_4$

Convert from grams to kilograms: $2.05 \times 10^7 \text{ g } CH_4 \times \frac{1 \text{ kg}}{10^3 \text{ g}} = 2.05 \times 10^4 \text{ kg } CH_4$

3 Evaluate **Does the result make sense?** Although the methane is compressed, its volume is still very large. So it is reasonable that the cavern contains a large mass of methane.

28. A child's lungs can hold 2.20 L. How many grams of air do her lungs hold at a pressure of 102 kPa and a body temperature of 37°C? Use a molar mass of 29 g for air, which is about 20% O_2 (32 g/mol) and 80% N_2 (28 g/mol).

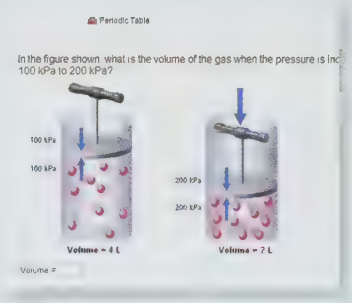


29. What volume will 12.0 g of oxygen gas (O_2) occupy at 25°C and a pressure of 52.7 kPa?

In Problems 28 and 29, make sure to express the temperature in kelvins before substituting for T in the ideal gas law equation.

466 Chapter 14 • Lesson 3

In the Teacher's Edition



Teacher support for problem-solving and math skills is provided in the Teacher's Edition wrap with **Foundations for Math** features.

Foundations for Math

SCIENTIFIC NOTATION Gas law calculations often result in very large or very small numbers. Converting these numbers to scientific notation makes them more manageable and easier to read. Before converting to scientific notation, students should identify the direction in which the decimal point needs to move. This determines the sign of the exponent. The direction of decimal point movement is determined by whether the number is greater than or less than one.

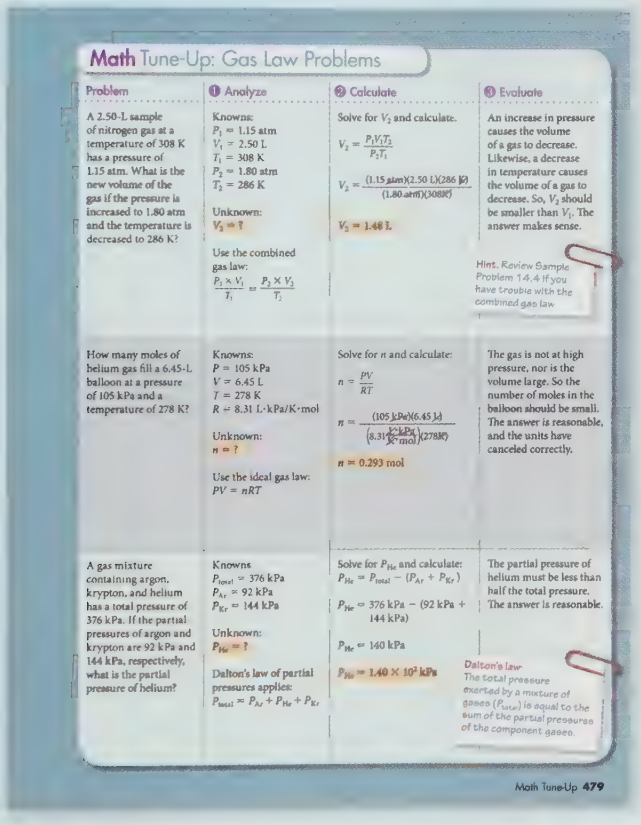
In **Sample Problem 14.5**, the answer is less than one, so the decimal point needs to move to the right in order to convert the number to scientific notation. Moving the decimal point to the right gives a negative exponent. In the sample problem, the decimal point moves two places to the right, so the exponent for 10 will be -2.

Periodic Table

In the figure shown, what is the volume of the gas when the pressure is increased from 100 kPa to 200 kPa?

100 kPa
100 kPa
Volume = 4 L
200 kPa
200 kPa
Volume = ? L

Online



Online Problem Sets give your students extra practice in solving problems similar to those you'll find in your textbook.

Math in the Science Classroom

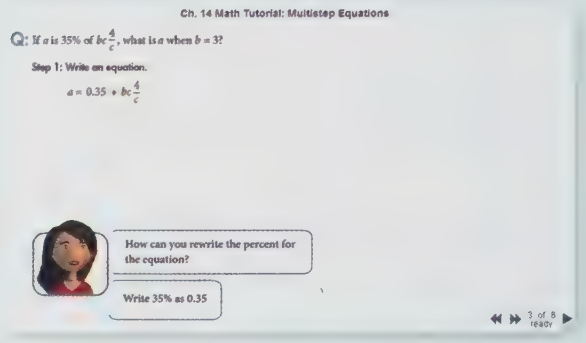
Why should students concern themselves with mathematics in your chemistry class? Good science requires good data from which to draw conclusions. Technology enhances the ability to measure in a variety of ways. Often scientists must measure large amounts of data, and thus an aim of analysis is to reduce the data to a summary that makes sense and is consistent with established norms of communication—i.e., mathematics. Mathematics is the language used by scientists to model change in the world.

In the Student Edition

Math Tune-Up pages at the end of each chapter help your students quickly reference how to solve a problem—and are also a great way to review before a test!

Math Tune-Up: Gas Law Problems

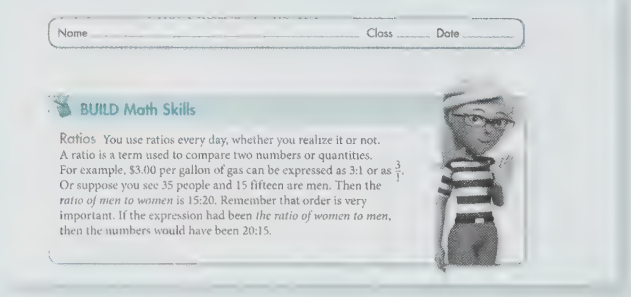
Problem	❶ Analyze	❷ Calculate	❸ Evaluate
A 2.50-L sample of nitrogen gas at a temperature of 308 K has a pressure of 1.15 atm. What is the new volume of the gas if the pressure is increased to 1.80 atm and the temperature is decreased to 286 K?	Knowns: $P_1 = 1.15$ atm, $V_1 = 2.50$ L, $T_1 = 308$ K, $P_2 = 1.80$ atm, $T_2 = 286$ K Unknown: $V_2 = ?$ Use the combined gas law: $\frac{P_1 \times V_1}{T_1} = \frac{P_2 \times V_2}{T_2}$	Solve for V_2 and calculate. $V_2 = \frac{P_1 V_1 T_2}{P_2 T_1}$ $V_2 = \frac{(1.15\ \text{atm})(2.50\ \text{L})(286\ \text{K})}{(1.80\ \text{atm})(308\ \text{K})}$ $V_2 = 1.48$ L	An increase in pressure causes the volume of a gas to decrease. Likewise, a decrease in temperature causes the volume of a gas to decrease. So, V_2 should be smaller than V_1. The answer makes sense. Hint. Review Sample Problem 14.4 if you have trouble with the combined gas law.
How many moles of helium gas fill a 6.45-L balloon at a pressure of 105 kPa and a temperature of 278 K?	Knowns: $P = 105$ kPa, $V = 6.45$ L, $T = 278$ K, $R = 8.31$ L·kPa/K·mol Unknown: $n = ?$ Use the ideal gas law: $PV = nRT$	Solve for n and calculate: $n = \frac{PV}{RT}$ $n = \frac{(105\ \text{kPa})(6.45\ \text{L})}{(8.31\ \frac{\text{L·kPa}}{\text{K·mol}})(278\ \text{K})}$ $n = 0.293$ mol	The gas is not at high pressure, nor is the volume large. So the number of moles in the balloon should be small. The answer is reasonable, and the units have canceled correctly.
A gas mixture containing argon, krypton, and helium has a total pressure of 376 kPa. If the partial pressures of argon and krypton are 92 kPa and 144 kPa, respectively, what is the partial pressure of helium?	Knowns $P_{total} = 376$ kPa $P_{Ar} = 92$ kPa $P_{Kr} = 144$ kPa Unknown: $P_{He} = ?$ Dalton's law of partial pressures applies: $P_{total} = P_{Ar} + P_{He} + P_{Kr}$	Solve for P_{He} and calculate: $P_{He} = P_{total} - (P_{Ar} + P_{Kr})$ $P_{He} = 376$ kPa − (92 kPa + 144 kPa) $P_{He} = 140$ kPa $P_{He} = 1.40 \times 10^2$ kPa	The partial pressure of helium must be less than half the total pressure. The answer is reasonable. Dalton's law The total pressure exerted by a mixture of gases (P_{total}) is equal to the sum of the partial pressures of the component gases.



Math Tune-Up 479

In the Teacher's Edition

Math support in the Teacher's Edition is geared toward the math objectives on high-stakes tests. Teaching notes provide you with strategies for alternative instruction and additional practice.



Online

Math Tutorial animations review key math skills that are needed to solve the chapter problems your students will see in their textbook.

In the Workbook

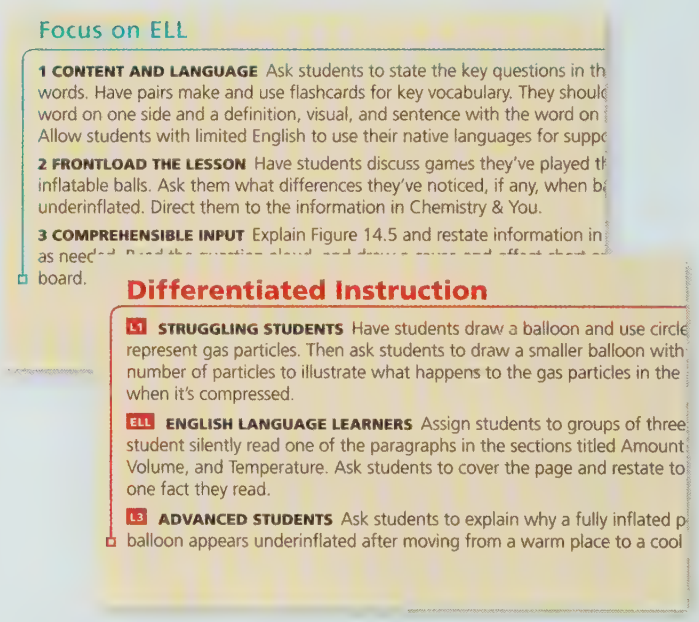
In the Reading and Study Workbook, students can find extra skill-building strategies to enhance the math support provided in the Student Edition.

Meeting Individual Needs of Your Classroom

What's different about each of the students in your classroom? Just about everything. A typical classroom is comprised of students whose differences include culture, language, interest, motivation, and knowledge.

Here's how *Pearson Chemistry* meets individual needs:

In the Student Edition



Considerate Text Structure

Ample, built-in reading support with elements before, during, and after each section of each lesson, and frequent use of analogies, are all part of a considerate text. The Guide for Reading helps students master concepts by introducing them to the Key Concepts, Vocabulary, and a Reading Strategy. The Key Concepts highlighted as boldfaced sentences encourage students to focus on the big ideas of chemistry. Lesson Checks allow students to review Key Concepts at the end of every lesson.

In the Teacher's Edition

Chapter Planning Guides label activities by levels of difficulty, meeting the needs of all students. All program resources are identified by levels for Conceptual, for Standard, and for Honors.

The Teacher's Edition includes Differentiated Instructional Support Ideas. In order to facilitate, these practical ideas for visual learning, English language learners, less proficient readers, advanced learners, and inclusion/special needs are placed at point-of-use areas throughout.

Focus on ELL

1 CONTENT AND LANGUAGE Ask students to state the key questions in th words. Have pairs make and use flashcards for key vocabulary. They shoul word on one side and a definition, visual, and sentence with the word on Allow students with limited English to use their native languages for supp

2 FRONTLOAD THE LESSON Have students discuss games they've played th inflatable balls. Ask them what differences they've noticed, if any, when b underinflated. Direct them to the information in Chemistry & You.

3 COMPREHENSIBLE INPUT Explain Figure 14.5 and restate information in as need

board.

Differentiated Instruction

L1 **STRUGGLING STUDENTS** Have students draw a balloon and use circle represent gas particles. Then ask students to draw a smaller balloon with number of particles to illustrate what happens to the gas particles in the when it's compressed.

ELL **ENGLISH LANGUAGE LEARNERS** Assign students to groups of three student silently read one of the paragraphs in the sections titled Amount Volume, and Temperature. Ask students to cover the page and restate to one fact they read.

L3 **ADVANCED STUDENTS** Ask students to explain why a fully inflated p balloon appears underinflated after moving from a warm place to a cool

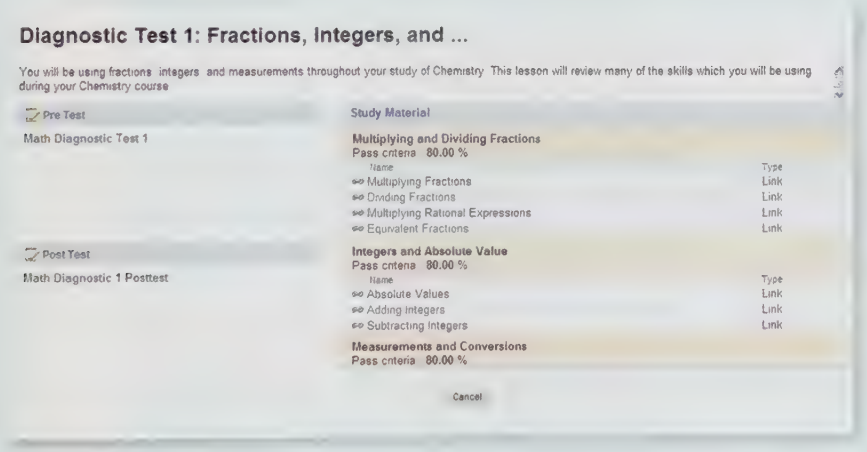
In the Workbook

The Reading and Study Workbook supports every lesson of the Student Edition, helping students with reading and math skills. Lesson summaries, instructional graphics, problem-solving tips, vocabulary reviews, and extension activities help contribute to a better understanding of core chemistry concepts.

Inform Instruction with Comprehensive Assessment

A variety of assessment opportunities in the *Pearson Chemistry for Indiana* program helps you monitor student progress, evaluate content mastery, and ensure student success on high-stakes tests.

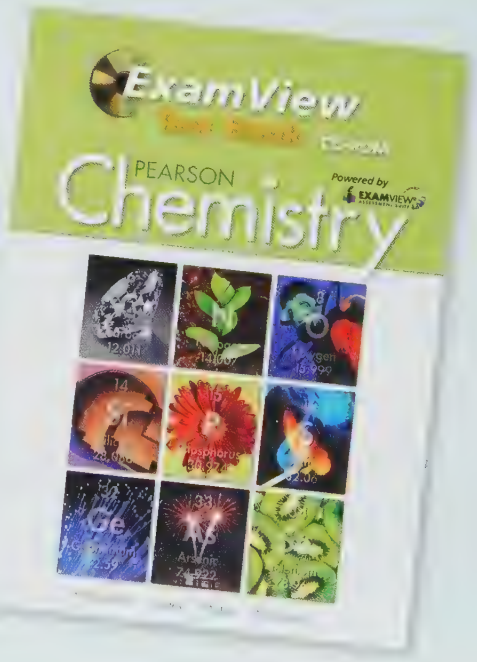
Assessment Monitors Learning



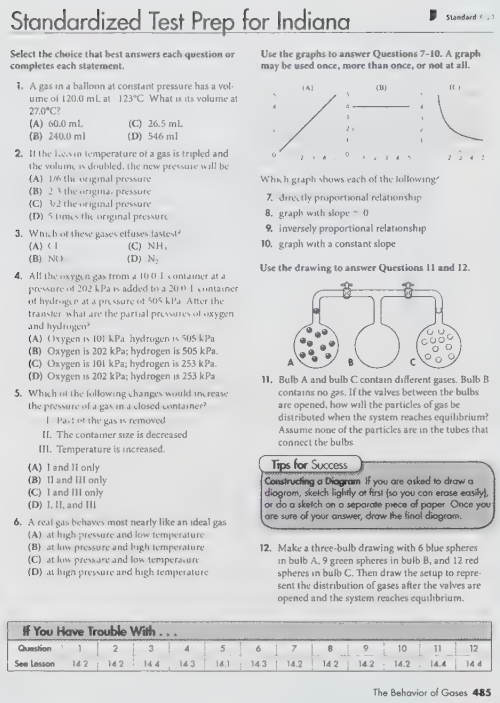
Lesson Checks at the end of each lesson call on students to think critically and apply vocabulary. Expanded chapter assessments offer students plenty of opportunity to master the concepts. (Solutions to asterisked assessment problems can be found in Appendix E of the Student Edition.) In addition, Standardized Test Prep pages in your state test format provide students practice on high-stakes exams. Additional assessment opportunities are offered in the Progress Monitoring Assessments book.

Editable Online Assessment Resource

Ensure that your students are mastering content with this brand-new assessment program! Assessments include leveled Unit Tests and leveled Chapter Tests to help you prepare your classroom for end-of-year testing.



Online Assessment and Remediation



PearsonChem.com provides diagnostic and Benchmark tests with automatic scoring, class reports, and remediation for students.

Indiana ExamView Assessment Suite CD-ROM

ExamView® Computer Test Bank CD-ROM provides you access to thousands of modifiable test questions, hundreds of which contain algorithmically-generated variable data. Create and print custom tests in minutes that correlate to your state standards with this test bank that is also compatible with QuickTake software.

Standardized Test Prep for Indiana

Standard

Select the choice that best answers each question or completes each statement.

1. A gas in a balloon at constant pressure has a volume of 120.0 mL at 123°C. What is its volume at 27.0°C?
(A) 60.0 mL (C) 26.5 mL
(B) 240.0 ml (D) 546 ml

2. If the Kelvin temperature of a gas is tripled and the volume is doubled, the new pressure will be
(A) 1/6 the original pressure
(B) 2/3 the original pressure
(C) 3/2 the original pressure
(D) 6 times the original pressure

3. Which of these gases effuses fastest?
(A) Cl (C) NH_3
(B) NO (D) N_2

4. All the oxygen gas from a 10.0 L container at a pressure of 202 kPa is added to a 20.0 L container of hydrogen at a pressure of 505 kPa. After the transfer, what are the partial pressures of oxygen and hydrogen?
(A) Oxygen is 101 kPa; hydrogen is 505 kPa.
(B) Oxygen is 202 kPa; hydrogen is 505 kPa.
(C) Oxygen is 101 kPa; hydrogen is 253 kPa.
(D) Oxygen is 202 kPa; hydrogen is 253 kPa.

5. Which of the following changes would increase the pressure of a gas in a closed container?
I. Part of the gas is removed.
II. The container size is decreased.
III. Temperature is increased.
(A) I and II only
(B) II and III only
(C) I and III only
(D) I, II, and III

6. A real gas behaves most nearly like an ideal gas
(A) at high pressure and low temperature.
(B) at low pressure and high temperature.
(C) at low pressure and low temperature.
(D) at high pressure and high temperature.

Use the graphs to answer Questions 7–10. A graph may be used once, more than once, or not at all.

Which graph shows each of the following?

7. directly proportional relationship
8. graph with slope = 0
9. inversely proportional relationship
10. graph with a constant slope

Use the drawing to answer Questions 11 and 12.

11. Bulb A and bulb C contain different gases. Bulb B contains no gas. If the valves between the bulbs are opened, how will the particles of gas be distributed when the system reaches equilibrium? Assume none of the particles are in the tubes that connect the bulbs.

Tips for Success
Constructing a Diagram If you are asked to draw a diagram, sketch lightly at first (so you can erase easily), or do a sketch on a separate piece of paper. Once you are sure of your answer, draw the final diagram.

12. Make a three-bulb drawing with 6 blue spheres in bulb A, 9 green spheres in bulb B, and 12 red spheres in bulb C. Then draw the setup to represent the distribution of gases after the valves are opened and the system reaches equilibrium.

If You Have Trouble With . . .

The Behavior of Gases 485

Each chapter assessment concludes with standardized test practice.

Course Overview

The overview lists Indiana's Academic Standards for Chemistry I. Use this chart to see the coverage of Indiana's Chemistry standards in this book. With the help of this chart, you can find solid, fully developed instruction on any standard.

The first part of Indiana's Academic Standards for Science consists of a set of eleven Nature of Science Standards. These standards address scientific methods and scientific thinking. In this front matter, these standards have been given the reference numbers NoS.1 through NoS.11.

With each content standard, you will find a Summary Phrase that is used to reference that standard throughout the Student Edition. The phrase is a convenient tool to help student's remember the basic content of each standard. The full content of each standard is listed in this chart.

Standard	Where You'll Find It
The Nature of Science Students should understand that scientific knowledge is gained from observation of natural phenomena and experimentation, by designing and conducting investigations guided by theory, and by evaluating and communicating the results of those investigations according to accepted procedures. Thus, scientific knowledge is scientists' best explanations for the data from many investigations. Further, ideas about objects in the microscopic world that we cannot directly sense are often understood in terms of concepts developed to understand objects in the macroscopic world that we can see and touch. In the science classroom student work should align with this process of science and should be guided by the following principles. These should be woven throughout the daily work that students are doing when learning the content presented in the standard indicators.	
NoS.1 Develop explanations based on reproducible data and observations gathered during laboratory investigations.	All Quick Labs Chemistry & You: pp. 208, 355, 744 All Small-Scale Labs
NoS.2 Recognize that their explanations must be based both on their data and other known information from investigations of others.	Small-Scale Lab: p. 545
NoS.3 Clearly communicate their ideas and results of investigations verbally and in written form using tables, graphs, diagrams, and photographs.	Lesson: 1.3 Quick Lab: pp. 180, 328, 354, 571, 896 All Small-Scale Labs
NoS.4 Regularly evaluate the work of their peers and in turn have their work evaluated by their peers.	Quick Lab: p. 109
NoS.5 Apply standard techniques in laboratory investigations to measure physical quantities in appropriate units and convert known quantities to other units as necessary.	Lessons: 12.1, 12.2, 12.3 Quick Lab: pp. 328, 571 Small-Scale Lab: pp. 92, 149, 184, 324, 545, 583
NoS.6 Use analogies and models (mathematical and physical) to simplify and represent systems that are difficult to understand or directly experience due to their size, time scale, or complexity, and recognize the limitations of analogies and models.	Lessons: 9.1, 12.1 Quick Lab: p. 230, 778 Chemistry & You: p. 316 Small-Scale Lab: pp. 184, 787
NoS.7 Focus on the development of explanatory models based on their observations during laboratory investigations.	Lessons: 4.1, 4.2, 4.3 Chemistry & You: p. 316 Small-Scale Lab: p. 184
NoS.8 Explain that the body of scientific knowledge is organized into major theories, which are derived from and supported by the results of many experiments, and allow us to make testable predictions.	Lessons: 1.1, 4.1, 4.2, 4.3

Course Overview *(continued)*

NoS.9 Recognize that new scientific discoveries often lead to a re-evaluation of previously accepted scientific knowledge and of commonly held ideas.	Lessons: 4.1, 4.2, 4.3, 5.1 Chemistry & You: p. 133
NoS.10 Describe how scientific discoveries lead to the development of new technologies, and conversely how technological advances can lead to scientific discoveries through new experimental methods and equipment.	Lesson: 5.3 Chemistry & You: pp. 133, 368, 736
NoS.11 Explain how scientific knowledge can be used to guide decisions on environmental and social issues.	Lesson: 1.2 Chemistry & You: pp. 52, 440, 476

Standard	Summary Phrase	Where You'll Find It
Standard 1: Properties and States of Matter **Core Standard:** Describe the nature of physical and chemical properties and changes of matter. **Core Standard:** Compare and contrast states of matter at the molecular level.		
C.1.1 Based on physical properties, differentiate between pure substances and mixtures	Pure substance or mixture?	Lessons: 2.1, 2.2 Quick Lab: p. 39 Chemistry & You: p. 52 Small-Scale Lab: p. 51
C.1.2 Observe and describe chemical and physical properties of different types of matter and designate them as either extensive or intensive.	Extensive and intensive properties	Lesson: 2.1
C.1.3 Recognize observable indicators of chemical changes.	Recognize chemical changes	Lesson: 2.4 Quick Lab: p. 699 CHEMystery: Ch 2
C.1.4 Describe physical and chemical changes at the molecular level.	Physical and chemical changes	Lessons: 2.1, 2.4, 11.1, 11.2, 11.3 Small-Scale Lab: p. 51
C.1.5 Describe the characteristics of solids, liquids, and gases and state changes at the molecular level.	States of matter	Lessons: 2.1, 13.1, 13.2, 13.2, 13.4 CHEMystery: Ch 13
C.1.6 Explain and apply the law of conservation of mass as it applies to chemical changes.	Conservation of mass: chemical changes	Lessons: 2.4, 12.1, 12.2 Chemistry & You: p. 355
C.1.7 Define density and distinguish between materials based on densities. Perform calculations involving density.	Density	Lesson: 3.2 Small-Scale Lab: p. 92

Standard	Summary Phrase	Where You'll Find It
Standard 2: Atomic Structure and the Periodic Table **Core Standard:** Describe how the properties and arrangement of the subatomic particles contributes to the structure of the atom. **Core Standard:** Describe how the structure of the periodic table reflects the numbers of electrons and protons and the configuration of the electrons in an atom.		
C.2.1 Describe how models of atomic structure changed over time based on available experimental evidence and understand the current model of atomic structure.	Modern atomic theory: historic development	Lessons: 4.1, 4.2, 4.3, 5.1, 5.2, 5.3
C.2.2 Describe how the subatomic particles (protons, neutrons, and electrons) contribute to the structure of an atom and recognize that the particles within the nucleus are held together against the electrical repulsion of the protons.	Subatomic particles and atomic structure	Lessons: 4.2, 4.3, 5.1, 5.2, 5.3, 22.1

C.2.3 Determine the number of protons, neutrons, and electrons in isotopes and in those isotopes that comprise a specific element. Relate these numbers to atomic number and mass number.	Isotopes, atomic number, and atomic mass	Lessons: 4.2, 4.3
C.2.4 Calculate the average atomic mass of an element from isotopic abundance data.	Average atomic mass	Lesson: 4.3
C.2.5 Write the electron configuration of an element and relate this to its position on the periodic table.	Write an element's electron configuration	Lesson: 6.2
C.2.6 Use the periodic table and electron configurations to determine an element's number of valence electrons and chemical and physical properties.	Determine valence electrons and properties	Lessons: 6.1, 6.2, 6.3, 7.1 Quick Lab: p. 180 Small-Scale Lab: pp. 184, 200
C.2.7 Compare and contrast nuclear reactions with chemical reactions. For nuclear reactions, describe how the fusion and fission processes transform elements present before the reaction into elements present after the reaction.	Compare and contrast nuclear reactions with chemical reactions	Lessons: 25.1, 25.2, 25.3, 25.4
C.2.8 Understand that the radioactive decay process is random for any given atom, but that this property leads to a predictable and measurable exponential decay of a sample of radioactive material. On this basis, calculate the half-life of a radioactive sample given its molarity and its decay rate.	Radioactive decay	Lesson: 25.2 CHEMystery: Ch 25 Chemistry & You: p. 892 Small-Scale Lab: p. 887
Standard	**Summary Phrase**	**Where You'll Find It**
Standard 3: Bonding and Molecular Structure **Core Standard:** Describe how the distribution of electrons within an atom determines its interactions with other atoms. **Core Standard:** Describe the attractive forces between molecules and their effect on chemical and physical properties.		
C.3.1 Describe, compare, and contrast the characteristics of the interactions between atoms in ionic and covalent compounds.	Interactions between atoms in ionic and covalent compunds	Lessons: 7.2, 8.1, 8.2, 8.3, 8.4 CHEMystery: Ch 7
C.3.2 Compare and contrast how ionic and covalent compounds form.	Formation of ionic and covalent compounds	Lessons: 7.2, 8.1, 8.2, 8.3, 8.4
C.3.3 Compare and contrast ionic, covalent network, metallic and polar and non-polar molecular crystals with respect to constituent particles, strength of bonds, melting and boiling points, and conductivity; provide examples of each type.	Molecular and atomic attractions	Lessons: 7.1, 7.2, 7.3, 8.1, 8.2, 8.3, 8.4, 13.2, 13.3, 15.1 Chemistry & You: p. 208
C.3.4 Draw structural formulas for and name simple molecules.	Structural formulas and names	Lessons: 8.3, 9.3, 9.4, 9.5, 22.1, 22.2, 22.3, 22.4 Chemistry & You: pp. 803, 821
C.3.5 Write chemical formulas for ionic compounds given their name and vice versa.	Write chemical formulas	Lessons: 9.1, 9.2

Course Overview *(continued)*

Standard	Summary Phrase	Where You'll Find It
Standard 4: Reactions and Stoichiometry **Core Standard:** Use balanced chemical equations and the mole concept to determine the quantities of reactants and products.		
C.4.1 Predict products of simple reactions such as synthesis, decomposition, single replacement and double replacement.	Predict products	Lessons: 11.1, 11.2, 11.3 CHEMystery: Ch 11
C.4.2 Balance chemical equations using the law of conservation of mass and use them to describe chemical reactions.	Balance chemical equations	Lessons: 11.1, 12.1, 23.1 Quick Lab: pp. 354, 404 Chemistry & You: p. 355 Small-Scale Lab: pp. 374, 399, 475
C.4.3 Use the mole concept to determine the number of moles and number of atoms or molecules in samples of elements and compounds, given mass of the sample.	The mole concept	Lessons: 10.1, 10.2, 10.3, 12.1, 12.2, 12.3 Quick Lab: p. 404 CHEMystery: Ch 10 Small-Scale Lab: pp. 324, 399
C.4.4 Using a balanced chemical equation, calculate the quantities of reactants needed and products made in a chemical reaction that goes to completion.	Calculate reactants and products	Lessons: 12.2, 12.3 Quick Lab: p. 404 Small-Scale Lab: p. 399
C.4.5 Describe, classify and give examples of various kinds of reactions-synthesis (combination), decomposition, single displacement, double displacement and combustion.	Classify types of reactions	Lessons: 11.2, 11.3, 23.1, 23.2, 23.3 Chemistry & You: p. 368
C.4.6 Determine oxidation states and identify the substances apparently gaining and losing electrons in redox reactions.	Redox reactions	Lessons: 20.1, 20.2, 20.3 CHEMystery: Ch 20 Chemistry & You: p. 700, 716
C.4.7 Perform calculations to determine percent composition by mass of a compound or mixture when given the formula.	Percent composition, empirical formulas, and molecular formulas	Lesson: 10.3 CHEMystery: Ch 10 Quick Lab: p. 328 Chemistry & You: p. 532
Standard	**Summary Phrase**	**Where You'll Find It**
Standard 5: Behavior of Gases **Core Standard:** Using the kinetic molecular theory, describe and explain the behavior of ideal gases. **Core Standard:** Examine the relationship between moles, volume, pressure, and temperature for ideal gases, using the ideal gas equation of state $pv = nRT$.		
C.5.1 Use kinetic molecular theory to explain changes in gas volumes, pressure, moles, and temperature.	Kinetic molecular theory	Lessons: 14.1, 14.2, 14.3 Quick Lab: p. 467
C.5.2 Using the ideal gas equation of state, pv =nRT, calculate the change in one variable when another variable is changed and the others are held constant.	Ideal gas equation	Lesson: 14.3
C.5.3 Given the equation for a chemical reaction involving one or more gases as reactants and/or products, calculate the volumes of gas assuming the reaction goes to completion and the ideal gas law holds.	Reactant and product calculations: gases	Lessons: 12.2, 12.3 Quick Lab: p. 467

Standard	Summary Phrase	Where You'll Find It
Standard 6: Thermochemistry **Core Standard:** Recognize that chemical reactions result in either the release or absorption of energy. **Core Standard:** Apply the law of conservation of energy.		
C.6.1 Explain that atoms and molecules that make up matter are in constant motion and that this motion increases as thermal energy increases.	Explain that atoms and molecules are in constant motion	Lessons: 13.1, 13.2, 13.3
C.6.2 Distinguish between the concepts of temperature and heat flow in macroscopic and microscopic terms.	Distinguish between temperature and heat flow	Lessons: 13.1, 13.2, 14.2
C.6.3 Solve problems involving heat flow and temperature changes, using known values of specific heat and/or phase change constants (latent heats).	Heat flow and temperature change problems	Lessons: 17.1, 17.2, 17.3, 17.4 Quick Lab: p. 571
C.6.4 Classify chemical reactions and phase changes as exothermic or endothermic.	Exothermic and endothermic reactions	Lessons: 17.3, 17.2 CHEMystery: Ch 17 Chemistry & You: p. 576
Standard	Summary Phrase	Where You'll Find It
Standard 7: Solutions **Core Standard:** Describe the composition and characteristics of solutions. **Core Standard:** Identify the factors that qualitatively affect solubility, reaction rates and dynamic equilibrium.		
C.7.1 Describe the composition and properties of types of solutions.	Composition and properties of solutions	Lessons: 15.1, 15.2, 15.3, 16.1, 16.2, 16.3, 16.4
C.7.2 Explain how temperature, pressure, and polarity of the solvent affect the solubility of a solute.	Factors affecting solubility	Lessons: 16.1, 18.4
C.7.3 Describe the concentration of solutes in solution in terms of molarity. Perform calculations using molarity, mass, and volume.	Molarity	Lesson: 16.4
C.7.4 Prepare a specific volume of a solution of a given molarity when provided with a known solute.	Prepare a solution	Lesson: 16.2 Small-Scale Lab: p. 545
C.7.5 Explain how the rate of a reaction is qualitatively affected by changes in concentration, temperature, surface area, and the use of a catalyst.	Factors affecting rate of reaction	Lessons: 18.1, 18.2
C.7.6 Write equilibrium expressions for reversible reactions.	Reversible reactions	Lesson: 18.3
Standard	Summary Phrase	Where You'll Find It
Standard 8: Acids and Bases **Core Standard:** Use acid-base definitions to identify acids and bases given their formulas and reactions. **Core Standard:** Explain the meaning of the value indicated by the pH scale in terms of the hydrogen ion concentration for any aqueous solution.		

C.8.1 Use Arrhenius and Bronsted-Lowry models to classify substances as acids or bases.	Arrhenius and Bronsted-Lowry	Lesson: 19.1
C.8.2 Describe the characteristic properties of acids and bases.	Properties of acids and bases	Lessons: 19.1, 19.2, 19.3, 19.4, 19.5
C.8.3 Compare and contrast the dissociation and strength of acids and bases in solution.	Dissociation and strength of acids and bases	Lesson: 19.3
C.8.4 Given the hydronium (H_3O^+) ion concentration in a solution, calculate the pH, and vice versa. Explain the meaning of these values.	Calculate pH and hydronium ion concentration	Lesson: 19.2
C.8.5 For an acid-base titration, calculate the concentration of an unknown solution.	Titration calculations	Lesson: 19.4
Standard	**Summary Phrase**	**Where You'll Find It**
Standard 9: Organic Chemistry and Biochemistry **Core Standard:** Describe the unique nature of carbon atoms demonstrated by their ability to bond to one another and other elements, forming countless carbon-based substances and macromolecules.		
C.9.1 Use structural formulas to illustrate carbon atoms' ability to bond covalently to form many different substances.	Use structural formulas: carbon atoms	Lessons: 22.1, 22.2, 22.3, 22.4
C.9.2 Identify the variety of molecular types formed by the covalent bonding of carbon atoms and describe the typical properties of these molecular types.	Identify the variety of carbon molecules	Lessons: 22.1, 22.2, 22.3, 22.4, 23.1

Lesson-by-Lesson Correlation and Pacing Guide

This chart helps you plan your instruction time. The specific Academic Standards covered in each lesson are provided. The Fast Track column indicates those lessons, features, and labs required to provide in-depth coverage of Indiana's Academic Standards for Chemistry I. Lessons, features, and labs providing supplementary information are indicated under Enrichments. Chapter pacing helps you plan how much time to spend teaching and assessing each chapter.

Chapters/Lessons	Academic Standards for Science	Fast Track	Enrichments
Chapter 1 Introduction to Chemistry		5 periods, 2.5 blocks	
1.1 The Scope of Chemistry	NoS.8		•
1.2 Chemistry and You	NoS.11		•
Chemistry & You			•
1.3 Thinking Like a Scientist	NoS.1, NoS.3		•
Small-Scale Lab	NoS.1		•
1.4 Problem Solving in Chemistry			•
Chapter 2 Matter and Change		5 periods, 2.5 blocks	
2.1 Properties of Matter	C.1.1, C.1.2, C.1.4, C.1.5	•	
2.2 Mixtures	C.1.1	•	
2.3 Elements and Compounds	NoS.1		•
2.4 Chemical Reactions	C.1.3, C.1.4, C.1.6	•	
Small-Scale Lab	C.1.1, C.1.4, NoS.1	•	
Chemistry & You	C.1.1, NoS.11		•

Chapters/Lessons	Academic Standards for Science	Fast Track	Enrichments
Chapter 3 Scientific Measurement		10 periods, 5 blocks	
3.1 Using and Expressing Measurements	NoS.1		•
Chemistry & You			•
3.2 Units of Measurement	C.1.7	•	
Chemistry & You			•
3.3 Solving Conversion Problems			•
Small-Scale Lab	C.1.7, NoS.1, NoS.5	•	
Chapter 4 Atomic Structure		5 periods, 2.5 blocks	
4.1 Defining the Atom	C.2.1, NoS.7, NoS.8, NoS.9	•	
4.2 Structure of the Nuclear Atom	C.2.1, C.2.2, C.2.3, NoS.1, NoS.4, NoS.7, NoS.8, NoS.9	•	
Chemistry & You			•
4.3 Distinguishing Among Atoms	C.2.1, C.2.2, C.2.3, C.2.4, NoS.7, NoS.8, NoS.9	•	
Small-Scale Lab	NoS.1		•
Chapter 5 Electrons in Atoms		5 periods, 2.5 blocks	
5.1 Revising the Atomic Model	C.2.1, C.2.2, NoS.9	•	
Chemistry & You	NoS.9, NoS.10		•
5.2 Electron Arrangement in Atoms	C.2.1, C.2.2	•	
5.3 Atomic Emission Spectra and the Quantum Mechanical Model	C.2.1, C.2.2, NoS.1, NoS.10	•	
Chemistry & You			•
Small-Scale Lab	NoS.1, NoS.5		•

Course Planning Options

Most chemistry teachers are faced with the challenge of educating students of varied academic abilities. It takes careful planning to map out a method by which students can best be exposed to the major topics in the high school chemistry curriculum.

Prentice Hall Chemistry is organized in a way that can meet the needs of a variety of students and teachers. The textbook is comprehensive enough to satisfy the most comprehensive high school chemistry curriculum, while remaining readable, interesting, and accessible to less-academically motivated students. In addition, the division of chapters into manageable numbered sections provides today's teachers with the flexibility needed to teach classes comprised of students with diverse learning levels.

Pages T20 and T21 contain section planning options to assist teachers in designing lessons that meet the needs of all students. Symbols are used as follows.

The Conceptual Curriculum

In recent years, more students have been required to take chemistry, either in a mainstream setting or in a conceptual chemistry course. Thus, classroom populations have more students with below-average academic abilities in reading comprehension and math skills. The conceptual curriculum allows for a more concrete approach to ensure these students achieve their maximum potential. Course options are designated with symbols as follows.

● **Concrete concepts**—These sections typically describe fundamental (concrete) chemical concepts without relying on highly theoretical (abstract) or mathematical principles. These topics will help students focus on qualitative aspects of chemistry.

❍ **More abstract concepts or math/problem-solving**—These sections offer a combination of concrete topics plus theoretically abstract topics and/or mathematically challenging problem solving. In these sections, the emphasis on theoretical aspects or the degree of problem solving can be determined by the teacher.

Some sections have no symbol because they are beyond the scope of a typical conceptual curriculum and do not include concepts that are prerequisites for later chapters.

The Standard Curriculum

The standard curriculum is designed for students considered average in ability and achievement levels. These students should have little difficulty reading and understanding most of the material presented, and they will have sufficient math skills for tackling the problems in the textbook. Course options are designated with symbols as follows.

■ **Core content**—These sections are suitable for all students in a standard curriculum. A course that includes most of these sections will prepare students for other science courses and for becoming scientifically literate citizens.

❑ **Extension topics**—These sections may be covered as time allows or according to the interest of the teacher and the needs and/or problem-solving skills of the students.

Some sections have no symbol because a teacher would not have sufficient time to cover the topic well, or because the material is too challenging or abstract, or is not usually required in state or national curricula. Assume if there is no symbol that the section is not a prerequisite for later chapters.

The Honors Curriculum

The standard curriculum is designed to be used for students considered above average in their reading comprehension and general scholastic abilities. These students should be able to master most of the content in the textbook with less time and effort. Course options are designated with symbols as follows.

▲ **Core honors content**—These sections are suitable for all students in an honors curriculum. A course including these sections will prepare students for advanced science courses and for college coursework.

△ **Options to accelerate**—These sections may be covered more rapidly using homework assignments. Students may only need to review this material because they have studied it in a previous course or a previous chapter.

Materials Lists

Master Solutions List

The following list gives directions for preparing all the chemical solutions necessary for doing all the Small-Scale Labs in **Pearson Chemistry**. The most efficient way to organize your small-scale lab is to make up the appropriate aqueous solutions, then use and replace them as needed. Store each solution in a plastic reagent bottle. Depending on the labs you do, some solutions will have to be replaced several times during the year; others will last the entire year. Most solutions are 0.1*M* or 0.2*M*. In no case is any solution of greater concentration than 1.0*M*. Except for sodium chloride, the labs do not require you to prepare multiple solutions for the same chemical.

For example, all the experiments that use sodium hydroxide use 0.5*M* NaOH.

Label each reagent bottle with the chemical formula, the concentration, the number of grams of solute per volume of solution, and the date. When the bottle is empty, simply replenish it by following the directions on the label, and change the date. When making dilute acid solutions from concentrated acids, always add acid to water slowly and carefully. The Teacher's Edition of the Small-Scale Chemistry Laboratory Manual has a combined list of solutions for the labs in the Student Edition and the Small-Scale Chemistry Laboratory Manual.

Solution	Preparation	Labs
alizarin yellow R, 0.02%	50 mg AYR in 250 mL	670
aluminum chloride, 0.2*M*	12.1 g $AlCl_3 \cdot 6H_2O$ in 250 mL	200
ammonia, 1.0*M*	67 mL of 15*M* NH_3 in 1.0 L **Caution! Using proper ventilation, add ammonia to water carefully and slowly!**	436, 508, 604
borax, 4%	10 g $Na_2B_4O_7 \cdot 10H_2O$ in 250 mL	828
bromocresol green*, 0.04%	100 mg BCG in 14.3 mL 0.01*M* NaOH; dilute to 250 mL	670
bromophenol blue*, 0.04%	100 mg BPB in 14.9 mL 0.01*M* NaOH; dilute to 250 mL	670
bromothymol blue*, 0.04%	100 mg BTB in 16.0 mL 0.01*M* NaOH; dilute to 250 mL	435, 475, 670, 752
calcium chloride, 0.5*M*	13.9 g $CaCl_2$ in 250 mL	200, 295, 374
copper(II) sulfate, 0.2*M*	12.5 g $CuSO_4 \cdot 5H_2O$ in 250 mL	51, 200, 295, 752, 849
ethanoic acid, 0.8*M* CH_3COOH	undiluted white vinegar	254, 435, 508, 717
hydrochloric acid, 1.0*M*	82 mL of 12*M* HCl in 1.0 L **Caution! Always add acid to water carefully and slowly!**	399, 508, 717, 849
hydrogen peroxide, 3% H_2O_2	undiluted household supply	51
iron(III) chloride, 0.1*M*	6.8 g $FeCl_3 \cdot 6H_2O$ in 25 mL of 1.0*M* NaCl; dilute to 250 mL	200, 295
lead(II) nitrate, 0.2*M*	16.6 g $Pb(NO_3)_2$ in 250 mL	295, 374
magnesium sulfate, 0.2*M*	6.0 g $MgSO_4$ in 250 mL	200, 295
metacresol purple*, 0.04%	100 mg MCP in 26.2 mL 0.01*M* NaOH; dilute to 250 mL	670

Master Solutions List *(continued)*

Solution	Preparation	Labs
methyl orange, 0.05%	125 mg MO in 250 mL	670
nitric acid, 1.0M	63 mL of 15.8M HNO_3 in 1.0 L **Caution! Always add acid to water carefully and slowly!**	508, 717
nickel(II) sulfate, 0.2M	2.94 g $NiSO_4$ in 100 mL	200
pH buffer, Solution A	14.9 g boric acid and 12.6 g citric acid in 1.2 L	670
pH buffer, Solution B	45.6 g $Na_3PO_4 \cdot 12H_2O$ in 1.2 L	670
phenolphthalein, 0.1%	250 mg phenolphthalein in 250 mL of 70% 2-propanol	670
potassium bromide, 0.2M	6.0 g KBr in 250 mL	752
potassium iodide, 0.1M	4.2 g KI in 250 mL	51
2-propanol (70% isoproponal)	undiluted rubbing alcohol	254, 508
silver nitrate, 0.05M	2.1 g $AgNO_3$ in 250 mL	200, 295, 374
sodium carbonate, 1.0M	26.5 g Na_2CO_3 in 250 mL	200, 295, 374
sodium chloride, 0.1%	1.0 g NaCl in 1.0 L	254
sodium chloride, 1.0M	14.6 g NaCl in 250 mL	200, 374, 752
sodium hydrogen sulfite, 1.0M	4.2 g $NaHSO_3$ in 250 mL	475
sodium hydroxide, 0.5M	20.0 g NaOH in 1.0 L	200, 295, 374, 399, 508, 849
sodium hypochlorite, 1%	50 mL liquid bleach (NaClO) in 200 mL	51
sodium phosphate, 0.1M	9.5 g $Na_3PO_4 \cdot 12H_2O$ in 250 mL	200, 295, 374
sodium sulfate, 0.2M	7.1 g Na_2SO_4 in 250 mL	295, 374, 752
starch, 20%	50 mL liquid starch in 200 mL	51, 752
sulfuric acid, 1.0M	56 mL of 18M H_2SO_4 in 1.0 L **Caution! Always add acid to water carefully and slowly!**	508, 717
thymol blue*, 0.04%	100 mg TB in 21.5 mL 0.01M NaOH; dilute to 250 mL	399, 670
zinc chloride, 0.2M	6.8 g $ZnCl_2$ in 250 mL	200

*If the indicator is available as the sodium salt, dissolve directly in 250 mL of deionized or distilled water.

Master Solids List

For each solid that can be poured, fill six 30- to 60-mL plastic pill vials. Use a 1/4-inch office punch to make a hole in each lid. Cover the holes with plastic tape. Label and store each set in a plastic ice cube tray.

Name	Labs
ammonium chloride, NH_4Cl	635
calcium carbonate, $CaCO_3$	324
calcium chloride, $CaCl_2$	435, 635
guar gum	828
iron, Fe (staples)	717
magnesium, Mg	717
magnesium sulfate, $MgSO_4$	508
potassium chloride, KCl	508, 635
potassium iodide, KI	508
sodium carbonate, Na_2CO_3	508
sodium chloride, NaCl (table salt)	51, 324, 508, 635
sodium chloride, NaCl (lab grade)	545
sodium hydrogen carbonate, $NaHCO_3$ (baking soda)	399, 508, 635
sodium phosphate, Na_3PO_4	635
sucrose (table sugar)	508, 545
zinc, Zn (galvanized nails)	717

zinc strip		744

Lab Safety

Chemistry teachers are no longer exempt from successful prosecution for accidents that occur in their classrooms. That threat, coupled with our increased awareness of the insidious effects of chemical exposure, explains the demand for safety education, particularly in science classrooms.

When it comes to laboratory chemistry, the safety of students and teachers is the primary concern of Prentice Hall. To that end, both the traditional Laboratory Manual and the Small-Scale Chemistry Laboratory Manual give detailed safety information for the student and the teacher at the beginning of each lab and in the front of each laboratory manual. In the Student Edition, the labs display appropriate safety icons, which are defined for the students in Appendix D.

Safety in the Chemistry Laboratory

The following information about safety issues in the high school chemistry laboratory is intended to be used by classroom chemistry teachers. This reference section is intended to be accessible to the teacher for planning demonstrations and preparing for lab. The material included here is by no means comprehensive. Prentice Hall takes no responsibility for the completeness of this information or for the implementation of these suggestions.

The safety of the students in a high school laboratory is traditionally assigned to the teacher. But the teacher teaches safety awareness by holding each student accountable for the safety of all other participants in the lab, including the teacher. Have students sign a safety contract at the beginning of the year. There is a sample contract in each laboratory manual. Of course, the teacher will most effectively teach safety awareness by modeling safe practices and by making a discussion of safety conerns the first priority for all lab activities. The following suggestions are intended to help you establish a program of safety awareness for staff and students.

Education

- Put together a safety committee for your school. Include faculty, students, and administrators.
- Schedule regular meetings of the safety committee to discuss issues, accident reports, and the results of lab inspections.
- Implement a safety education program for staff and students.
- Require students to know the lab safety rules, assess this by giving a safety quiz, and have the students sign a safety contract, saying that they know the rules and will comply with them. Send the contract home with a set of rules and require that one parent or guardian sign the contract, having read the rules.
- Give a safety grade with each lab, based on each student's behavior during the lab. Penalize unsafe behavior by removing students from the lab.
- Encourage school staff to become certified in CPR and first aid.
- Require that science staff read any of several publications on safety in the high school science classroom.

Management

- Report all accidents to the safety committee.
- Periodically inspect laboratories and report findings to the safety committee.
- Establish an emergency plan and review it periodically with students and staff.
- Keep phone numbers for the fire department, police department, local ambulance, and poison control center next to every phone in a lab or stockroom.
- Display warning signs and safety posters.
- Prohibit student access to stockrooms.
- Require students to keep aisles clear and counters clean. There should be two exits in a laboratory or stockroom, and they should be kept free of obstacles.
- Keep a current chemical inventory. Update the chemical inventory often. Include a Material Safety Data Sheet (MSDS) for each chemical.
- Label all chemicals with the date and possible hazards. Establish a policy for disposing of and buying chemicals.
- In prelab discussions, stress safety issues relevant to each specific lab.

Lab Techniques

- Do not allow any student or staff member to work alone in the laboratory.
- Do not leave any experiment unattended.
- Do not eat, smoke, or drink in the lab.
- Do not store food in chemical refrigerators. Store chemicals only in chemical refrigerators.
- Never taste a chemical in the laboratory.
- Always add acids to water, never water to acids.
- When pipetting, use a suction bulb. Never use your mouth.
- When heating the contents of a test tube, direct the mouth of the test tube away from yourself and away from others.

Personal Safety

- Always wear goggles in lab. Require students and anyone entering the lab to wear goggles.
- Provide lab coats and aprons for all participants in the lab.
- Take into account student health problems such as allergies or asthma.
- Do not allow untied long hair, loose clothing, bare feet, open-toed or -heeled shoes, or dangling jewelry to be worn in the lab.
- Strongly discourage the wearing of contact lenses in lab. In the event of a chemical splash into the eye, the lenses may hold chemicals in contact with the eye, potentially causing greater injury.

Equipment

- Make available the following items in all labs and demonstration areas: an ABC fire extinguisher, a smoke alarm, a safety shower, an eye-wash faucet, a fume hood.
- Maintain and check all safety equipment regularly.
- Keep a first-aid kit stocked and available.
- Keep flammable chemicals in an approved fireproof cabinet.
- Attach compressed gas cylinders to counters or walls. Move them on dollies on which they are secured.
- Use safety shields when there is a possibility of explosion, implosion, chemical splashing, or fire.
- Use hot plates in lieu of open flames as often as possible.
- Use dispensing devices such as syringes, spigots, or droppers, rather than having students pour chemicals from their containers.
- Be prepared for spills, especially acid spills. Spill-control devices are available from suppliers. To avoid mercury spills, use alcohol thermometers.

Storing Chemicals

- Store chemicals in stockrooms, not in the lab.
- Do not store chemicals alphabetically. Use an approved system of chemical storage, and post legends in the stockroom.
- Store only the chemicals you will use during a school year.

Disposal

- Dispose of broken glass in a dedicated container kept out of the way and clearly labeled.
- Dispose of chemicals in the following ways:

  Neutralize acids and bases and flush down the drain.

  Flush light metal salts and their solutions down the drain with excess water.

  Precipitate and filter heavy metals. Evaporate heavy metal solutions down to salt. Keep heavy metals salts in labeled containers and dispose of them by following local regulations.

  When in doubt, check with local authorities about local regulations.

- Have a disposal plan for each lab, and include directions for disposal in your prelab discussion.

About the Authors

Michael Matta earned a Bachelor of Science in chemistry at the University of Dayton and a Doctor of Philosophy in chemistry at Indiana University. He spent most of his career at Southern Illinois University Edwardsville, where he currently is an Emeritus Professor. Dr. Matta has been developing and writing high school and college-level chemistry textbooks and related ancillaries for over 30 years and has published extensively in scientific journals. He is a member of several professional societies. In his spare time, he enjoys woodworking, watercolor painting, and playing with his six grandchildren.

Dennis Staley earned a Master of Science in chemistry at Southern Illinois University Edwardsville. As an Instructor in the Department of Chemistry and the Office of Science and Math Education at Southern Illinois University Edwardsville, he taught high school and college-level chemistry and led teacher workshops. Mr. Staley has been writing high school and college-level chemistry textbooks for over 30 years. He currently enjoys gardening, bicycling, sharing hands-on science with kids, and traveling to visit his grandchildren.

Antony Wilbraham spent the majority of his career at Southern Illinois University Edwardsville, where he currently holds the position of Emeritus Professor of Chemistry. He is a member of several professional societies. For more than 30 years, he has been writing high school and college-level chemistry textbooks and has published extensively in scientific journals. Professor Wilbraham enjoys traveling, woodworking, gardening, and making toys for his granddaughters.

Edward Waterman taught chemistry and advanced placement chemistry from 1976 to 2007 at Rocky Mountain High School in Fort Collins, Colorado. He now conducts workshops for teachers on inquiry, differentiation, small-scale chemistry, AP chemistry and virtual chemistry laboratory. He also presents photo-essay lectures about the natural history of molecules, engaging the general public in the appreciation for and understanding of chemistry. Mr. Waterman holds a Bachelor of Science degree in chemistry from Montana State University and a Master of Science degree in chemistry from Colorado State University. In his free time, he enjoys exploring wild places in the Rocky Mountains and on the Colorado Plateau by hiking, kayaking, and cross-country skiing.

All the Elements for Success

The new **Pearson Chemistry** program, created specifically for Indiana, combines proven content with cutting-edge digital support and a variety of lab investigations to help ensure your success in chemistry.

In your new program, you'll find:

- **Personalized learning** opportunities to support your unique learning style on your path to mastery of the Indiana Academic Standards.
- **Connections to the real world** relate abstract concepts and processes to your every day life.
- **Cutting-edge technology** that is integrated throughout the program providing options for you to interact with the content in multiple ways.
- **Rich lab explorations** and **study support** provide numerous opportunities to practice and reinforce essential chemistry skills.

In the following pages, you'll see just a few of the elements contained in your **Pearson Chemistry** for Indiana program that will lead to your success!

Big Ideas ensure that the lesson is centered around the most important concepts of each chapter. Essential Questions that support the Big Idea organize and set the focus for the chapter.

22
Hydrocarbon Compounds

INSIDE:
- 22.1 Hydrocarbons
- 22.2 Unsaturated Hydrocarbons
- 22.3 Isomers
- 22.4 Hydrocarbon Rings
- 22.5 Hydrocarbons From Earth's Crust

PearsonChemistry.com

Turkmenistan has some of the world's largest deposits of natural gas. This natural gas deposit in the city of Darvaza has been burning for over three decades!

760

BIG IDEA

CARBON CHEMISTRY

Essential Questions:
1. *How are hydrocarbons named?*
2. *What are the general properties of hydrocarbons?*

CHEMYSTERY

Nose for Hire

Walking home from school one day, Anthony spotted a poster soliciting participants for a smell test. The poster offered participants "$50 for less than an hour of your time." So he decided to go for it.

When Anthony reported for the study, after filling out some paperwork, a researcher asked him to smell two chemical samples. The first one smelled like a freshly cut orange. The second had an odor that reminded him of pine trees.

Anthony was curious. "What am I smelling?" he asked. "Limonene," the researcher answered. "What about the second one?" Anthony asked. The researcher gave the same reply: "Limonene." Anthony was perplexed. How could two substances, both with the name limonene, smell so different?

▶ Connect to the BIG IDEA As you read about hydrocarbons, think about what could make this phenomenon possible.

INDIANA'S ACADEMIC STANDARDS FOR SCIENCE

Atomic Structure and the Periodic Table C.2.2; **Bonding and Molecular Structure** C.3.4; **Organic Chemistry and Biochemistry** C.9.1, C.9.2. See lessons for details.

CHEMystery features present mini-mysteries that take the Big Idea a step further into a practical context. Once you study the chapter, you'll have the opportunity to solve the mystery and understand how it connects to the Big Idea.

Personalized Learning

Each student approaches learning in a variety of ways. **Pearson Chemistry** for Indiana provides all the tools to support your unique style to help you master the Indiana Academic Standards. Sample chemistry problems and math support are just a few examples.

Math Tune-Up pages at the end of each chapter help you quickly reference how to solve a problem—and are also a great way to review before your test!

Sample Problems guide you step-by-step through complicated chemistry problems. Remember to look for the orange button to get more practice problems.

Math Tune-Up: Conversion Problems

Problem	❶ Analyze	❷ Calculate	❸ Evaluate
A grocer is selling oranges at 3 for $2. How much would it cost to buy a dozen oranges?	Knowns: 3 oranges = $2; 1 dozen = 12 Unknown: Cost of 12 oranges = ? The desired conversion is oranges → $.	Use the relationship 3 oranges = $2 to write the correct conversion factor. $\frac{\$2}{3\ \text{oranges}}$ Multiply the known quantity by the conversion factor. $12\ \text{oranges} \times \frac{\$2}{3\ \text{oranges}} = \$8$	A dozen is larger than the number 3, so the cost should exceed $2. The known unit (oranges) cancels, and the answer has the correct unit ($).
Convert the volume 865 cm^3 to liters.	Knowns: volume = 865 cm^3; $10^3\ cm^3 = 1\ L$ Unknown: volume = ? L The desired conversion is $cm^3 \rightarrow L$.	Use the relationship $10^3\ cm^3 = 1\ L$ to write the correct conversion factor. $\frac{1\ L}{10^3\ cm^3}$ Multiply the known volume by the conversion factor. $865\ cm^3 \times \frac{1\ L}{10^3\ cm^3} = 0.865\ L$	A cubic centimeter is much smaller than a liter, so the answer should be numerically smaller than the given measurement. The known unit (cm^3) cancels, and the answer has the correct unit (L).
Express the length 8.2×10^{-4} µm in centimeters.	Knowns: length = 8.2×10^{-4} µm; 10^6 µm = 1 m; 1 m = 10^2 cm Unknown: length = ? L The desired conversion is µm → cm. First change µm to m; then change m to cm: µm → m → cm	Use the relationship 10^6 µm = 1 m to write the first conversion factor. $\frac{1\ m}{10^6\ \mu m}$ Use the relationship 1 m = 10^2 cm to write the second conversion factor. $\frac{10^2\ cm}{1\ m}$ Multiply the known length by the conversion factors. $8.2 \times 10^{-4}\ \mu m \times \frac{1\ m}{10^6\ \mu m} \times \frac{10^2\ cm}{1\ m} = 8.2 \times 10^{-8}\ cm$	A micrometer is smaller than a centimeter, so the answer should be numerically smaller than the given measurement. The known unit (µm) cancels, and the answer has the correct unit (cm). Hint: For a multistep problem, take it one conversion at a time.

94 Chapter 3 • Math Tune-Up

Sample Problem 3.5

Significant Figures in Multiplication and Division

Perform the following operations. Give the answers to the correct number of significant figures.

a. 7.55 meters × 0.34 meter
b. 2.10 meters × 0.70 meter
c. 2.4526 $meters^2$ ÷ 8.4 meters
d. 0.365 $meter^2$ ÷ 0.0200 meter

❶ **Analyze** **Identify the relevant concepts.** Perform the specified math operation, and then round the answer to match the measurement with the least number of significant figures.

❷ **Solve** **Apply the concepts to this problem.**

a. 7.55 meters × 0.34 meter = 2.567 $(meter)^2$
= 2.6 $meters^2$

b. 2.10 meters × 0.70 meter = 1.47 $(meter)^2$
= 1.5 $meters^2$

c. 2.4526 $meters^2$ ÷ 8.4 meters = 0.291 976 meter
= 0.29 meter

d. 0.365 $meters^2$ ÷ 0.0200 meter = 18.25 meters
= 18.3 meters

10. Solve each problem. Give your answers to the correct number of significant figures and in scientific notation.

a. 8.3 meters × 2.22 meters
b. 8432 $meters^2$ ÷ 12.5 meters
c. 35.2 seconds × $\frac{1\ \text{minute}}{60\ \text{seconds}}$

11. Calculate the volume of a warehouse that has measured dimensions of 22.4 meters by 11.3 meters by 5.2 meters. (Volume = l × w × h)

In Problem 11, the measurement with the fewest significant figures is 5.2 meters. What does this tell you?

Scientific Measurement 71

Connecting Chemistry to your World

Chemistry connections are all around you. **Pearson Chemistry** for Indiana provides examples of chemistry in daily life, connecting content to familiar examples and experiences in your world.

Chemistry & You engaging questions begin each lesson to help spark your curiosity and guide your learning.

22.1 Hydrocarbo

C.2.2 Subatomic particles and atomic structure; C.3.4 Structural formulas and names; C.9.1 Use structural formulas: carbon atoms; C.9.2 Identify the variety of carbon molecules.

CHEMISTRY & YOU

Q: *Why are some fossil fuels gases, some liquids, and some solids?* The gasoline used to fuel this motorcycle is a liquid at STP. So are the diesel fuel used in trucks and buses, and the kerosene used in lanterns. Other fuels are gases or solids. For example, the fuel used in a furnace might be natural gas or a solid such as coal. All these fuels contain mixtures of compounds called hydrocarbons. In this lesson, you will learn about the structure and properties of hydrocarbons.

Chemistry & You features throughout your book showcase exciting real world applications of chemistry in technology, the environment, and in numerous careers.

Key Questions

- *Why does a carbon atom form four covalent bonds?*
- *What are two possible arrangements of carbon atoms in an alkane?*

Vocabulary

- hydrocarbon
- alkane
- straight-chain alkane
- homologous series
- condensed structural formula
- substituent
- alkyl group
- branched-chain alkane

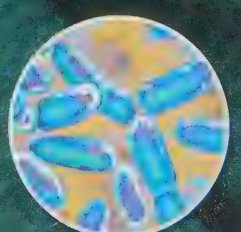
762 Chapter 22 • Lesson 1

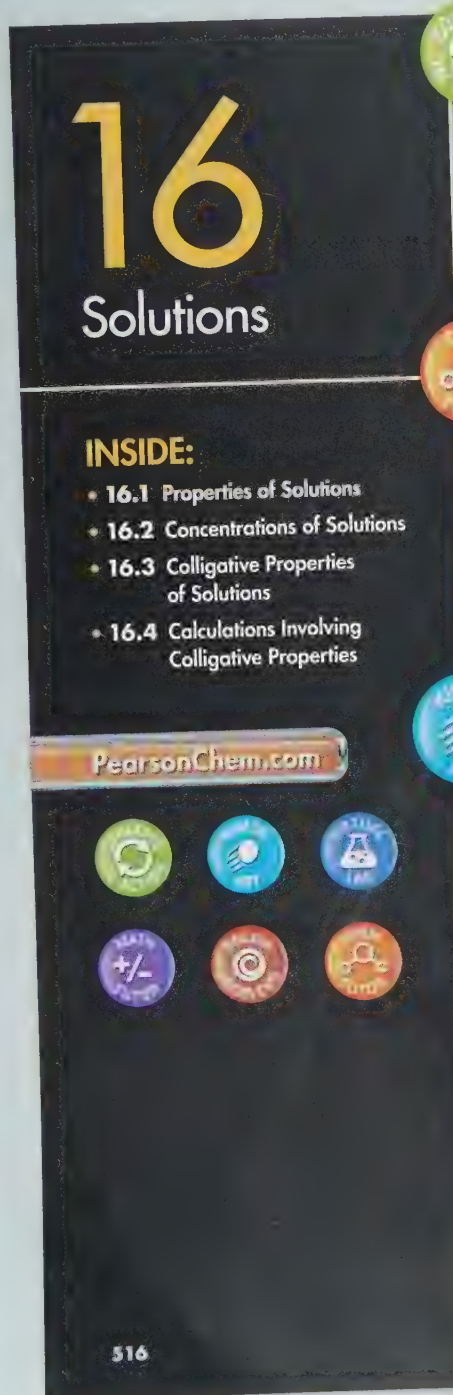
CHEMISTRY & YOU: TECHNOLOGY



Bioremediation

Oil and water don't mix. You may have witnessed this fact watching footage of an oil spill in the news. Oil spills can lead to the death of sea birds and marine mammals and can contaminate soil and drinking water.

One tool being used to clean up spilled oil is a relatively new technology called bioremediation. The technology uses "eating" microbes—particularly bacteria—to remedy the spill. For these microbes, the hydrocarbons in crude oil are not a contaminant but a food source. During the digestion process, harmful hydrocarbons are converted to less harmful products—mainly carbon dioxide and water. Bioremediation is a safe, simple, and relatively inexpensive method of dealing with spilled oil. However, the process takes time to work. In addition, it is usually only effective on residual oil on shorelines, after part of the spill has been removed by other means.



Take It Further

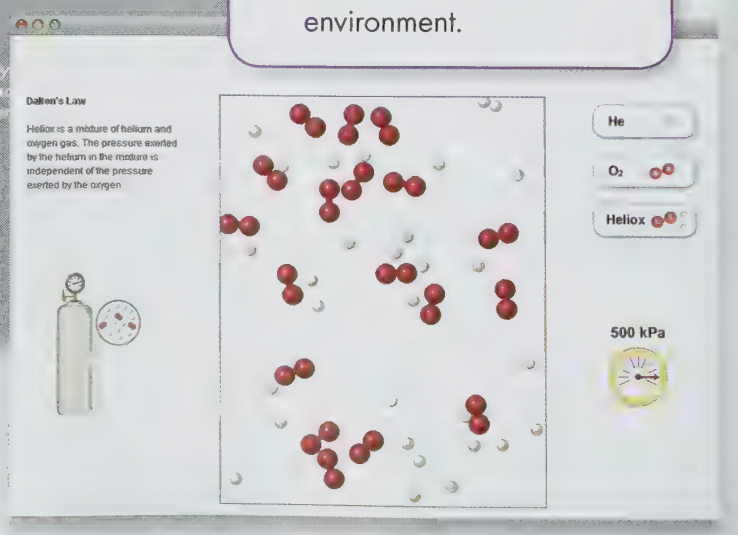
1. **Describe** Two hydrocarbons found in crude oil spills are methylbenzene and methylcyclopentane. Draw structural formulas for these two compounds.
2. **Research a Problem** Another technology called a dispersion agent is often used to remedy oil spills. Research this technology and compare it to bioremediation.

HIGH-TECH . . . AND ALIVE The [illegible] including the *Pseudomonas* species shown here.

Integrating Chemistry and Technology

Pearson Chemistry for Indiana comes alive online with numerous ways to practice, tutors to step through chemistry and math problems, online labs, interactive art, animations and much more to expand your learning beyond the classroom. The buttons throughout the text direct you to exciting and helpful online activities on PearsonChem.com.

Concepts in Action animations provide an overview of a key chapter concept using real-world contexts and concrete examples and analogies.



Chem Tutorial animations give you extra problem-solving help by demonstrating the steps shown in one or more selected Sample Problems from the chapter.

Kinetic Art animations help you grasp abstract concepts by bringing art from your textbook to life online.

Math Tutorial animations review key math skills that are needed to solve the chapter problems you'll see in your textbook. It shows you a 2–3 minute video that will walk you through the steps to solve a specific type of problem.

Online Problem Sets give you extra practice solving problems similar to those you'll find in your textbook.

Directed Virtual Lab activities guide you through Virtual ChemLab investigations designed to explain and reinforce chapter concepts in a virtual and realistic lab environment.

Pearson is pleased to partner with **Molecular Workbench** for all Kinetic Art animations.

Lab Investigations and Study Tools

Laboratory Investigations and Study Tools extend your understanding of chemistry concepts by providing you with hands-on practice and extra study support in the areas you need most.

Name _____ Date _____ Class _____

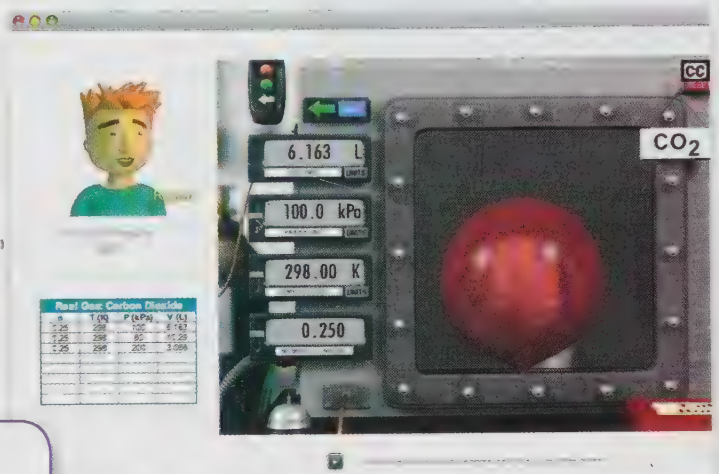
SMALL-SCALE LAB: Electrolytes

Laboratory Recordsheet — Use with Section 15.2

SAFETY

Wear safety glasses and follow the standard safety procedures outlined in the Small-Scale Lab Manual.

PURPOSE



To classify compounds as electrolytes by testing their conductivity in aqueous solution.

MATERIALS

- pencil
- paper
- ruler
- reaction surface
- conductivity tester
- chemicals shown in grid below
- water
- micropipet or dropper
- conductivity probe (optional)

PROCEDURE

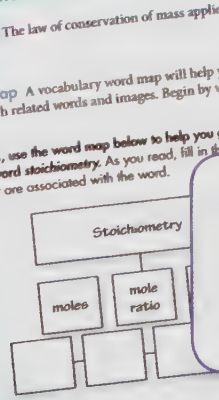
On a separate sheet of paper, draw a grid similar to the one below. Make each square 2 cm on each side. Place a reaction surface over the grid and place a few grains of each solid in the indicated places. Test each solid for conductivity. Then add 1 drop of water to each solid and test the wet mixture for conductivity. Be sure to clean and dry the conductivity leads between each test. Use the grid as a data table to record your observations.

Online Editable Labs will help your teacher design a laboratory experience to meet your needs, sourced from hundreds of possible activities including chapter labs, quick labs, small-scale labs, and probeware labs.

Name _____ Class _____ Date _____

12 Stoichiometry

Big idea: THE MOLE AND QUANTIFYING MATTER, REACTIONS



12.1 The Arithmetic of Equations

Essential Understanding: The law of conservation of mass applies to all chemical equations.

Reading Strategy

Vocabulary Word Map A vocabulary word map will help you learn vocabulary by associating the word with related words and images. Begin by writing word *stoichiometry* in the top box.

As you read Lesson 12.1, use the word map below to help you get a better understanding of the meaning of the word *stoichiometry*. As you read, fill in the other boxes with terms, phrases, or images that are associated with the word.

Name _____ Class _____ Date _____

BUILD Math Skills

Ratios You use ratios every day, whether you realize it or not. A ratio is a term used to compare two numbers or quantities. For example, $3.00 per gallon of gas can be expressed as 3:1 or as $\frac{3}{1}$. Or suppose you see 35 people and 15 fifteen are men. Then the *ratio of men to women* is 15:20. Remember that order is very important. If the expression had been *the ratio of women to men*, then the numbers would have been 20:15.

If you write the ratio of white paint to red paint incorrectly, you'll get a different shade of pink.

$\frac{1 \text{ white}}{3 \text{ red}}$ = dark pink $\frac{3 \text{ white}}{1 \text{ red}}$ = light pink

to 5 parts blue paint.

10 mm = 1 cm) _____ of their heights? (Hint:

3. Miguel and Ellen have to share a prize of $50 at a ratio of 2/3. How much does each get? (Hint: 1 share = $10) _____

A Reading and Study Workbook helps to increase your comprehension with lesson summaries, reading strategies, writing activities, math practice, and quizzes.

Materials List

For the Student

Quick Lab p 17
- 3 plastic drinking cups
- liquid dish detergent
- measuring cup and spoons
- water
- table sugar
- table salt

For the Teacher

Teacher Demo, p 7
- slides that show a wide variety of events or structures
- projector

Class Activity, p 15
- 250 mg of phenolphthalein
- 250 mL of 70% solution 2–propanol
- small artist's paintbrush
- sheets of copy paper or white butcher paper
- household glass cleaner containing ammonia

Teacher Demo, p 25
- bowl of ice cubes
- empty narrow neck (soda) bottle

CHAPTER 1

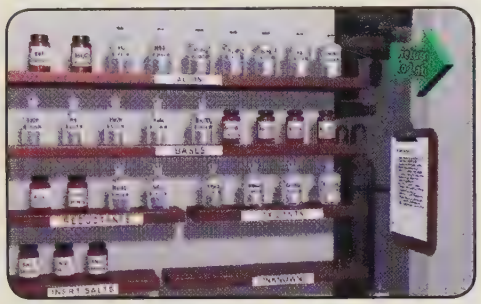
1 Introduction to Chemistry

INSIDE:

- 1.1 The Scope of Chemistry
- 1.2 Chemistry and You
- 1.3 Thinking Like a Scientist
- 1.4 Problem Solving in Chemistry

PearsonChem.com

A chemist is working in a lab, collecting scientific data. In this chapter, you will learn about the scientific method.



What's Online

CHEM TUTOR Students access guided, step-by-step tutorials for solving various numeric problems.

PROBLEM SETS Students can practice key problem-solving skills in an online problem set.

MATH HELP Identify the students that struggle with math by assigning an online math skills diagnostic test. These students can then improve and practice math skills by using the MathXL tutorial system.

VIRTUAL LAB Students go on an animated virtual lab tour in which laboratory safety procedures are studied in a simulated laboratory environment.

KINETIC ART Student watch animations of selected figures from the chapter followed by questions to check for understanding.

CONCEPTS IN ACTION Students watch an overview of a key chapter concept using real-world contexts and concrete examples and analogies. Each activity includes an interactive animation followed by analysis questions.

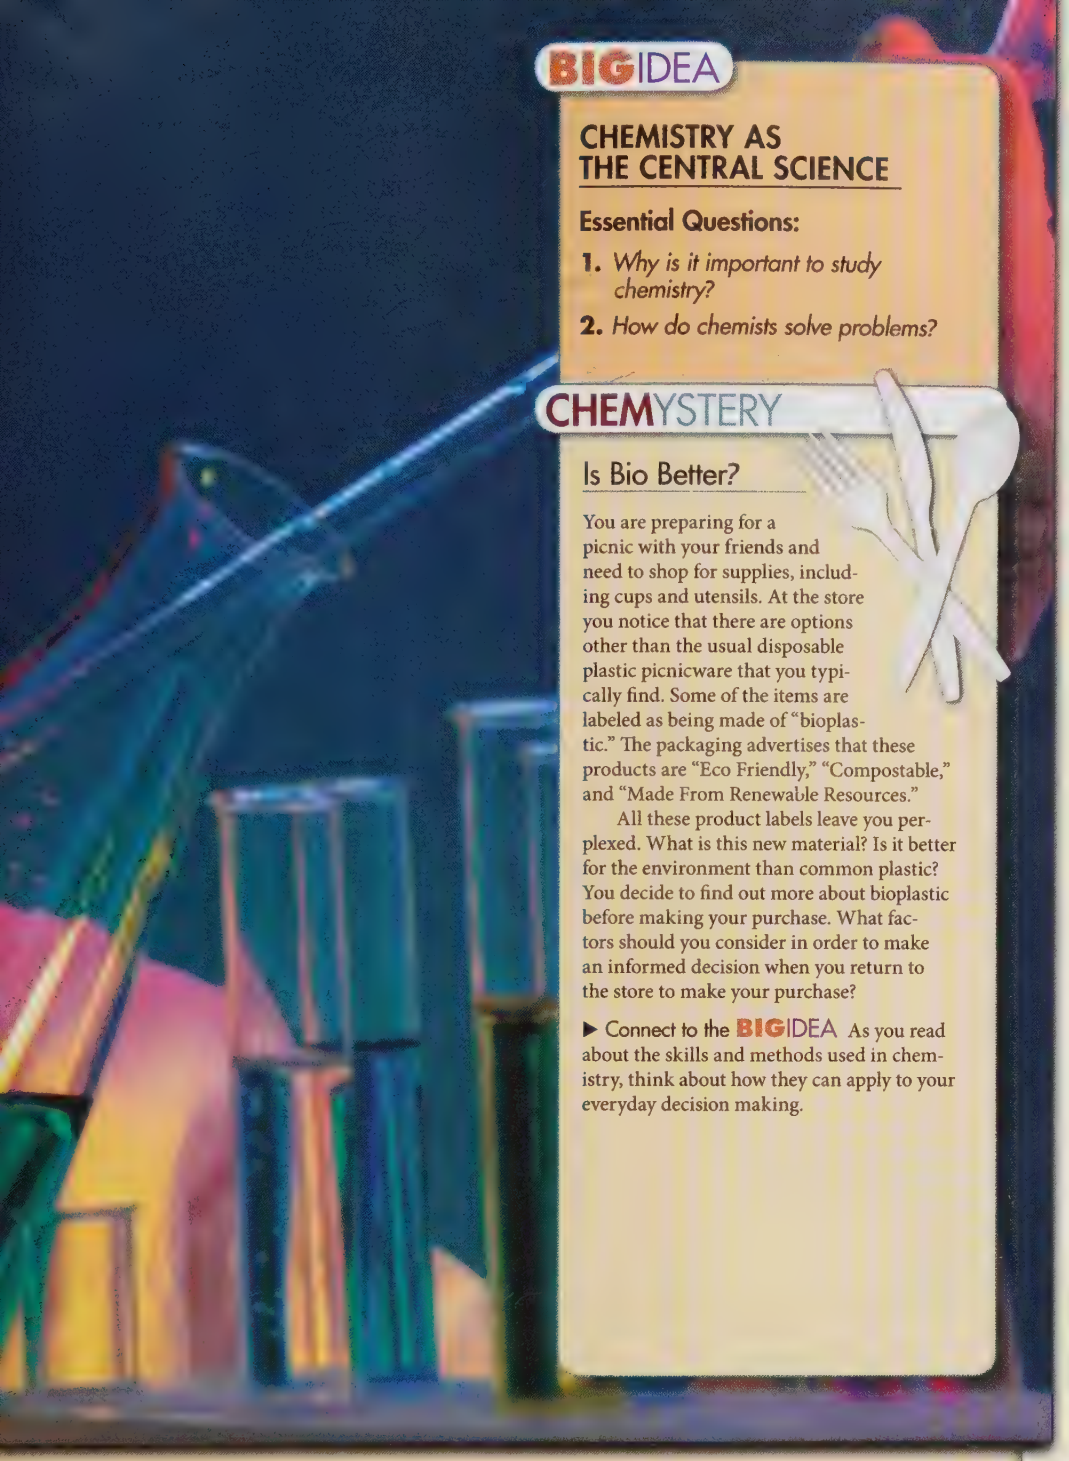
IN ACADEMIC STANDARDS for SCIENCE

Nature of Science

- Develop explanations based on reproducible data and observations gathered during laboratory investigations.
- Clearly communicate their ideas and results of investigations verbally and in written form using tables, graphs, diagrams, and photographs.
- Explain that the body of scientific knowledge is organized into major theories, which are derived from and supported by the results of many experiments, and allow us to make testable predictions.
- Explain how scientific knowledge can be used to guide decisions on environmental and social issues.

Focus on ELL

1 CONTENT AND LANGUAGE Have student volunteers read the chapter and lesson titles out loud, and assist them with pronunciation as necessary. Clarify for the students that the words *scope* and *problem* have both common and scientific meanings. Have students work in groups to create Frayer models for each word, including definitions, parts of speech, characteristics, examples, and nonexamples.



BEGINNING

LOW Create a drawing or symbol for each word, and present a native-language definition if you are literate in students' native language.

HIGH Write the word, and point to it while saying it out loud. Have students repeat the word after you.

INTERMEDIATE: LOW/HIGH Brainstorm examples and nonexamples and present to the class.

ADVANCED: LOW/HIGH Have students look up definitions and rewrite in their own words.

BIGIDEA

CHEMISTRY AS THE CENTRAL SCIENCE

Essential Questions:

1. *Why is it important to study chemistry?*
2. *How do chemists solve problems?*

CHEMYSTERY

Is Bio Better?

You are preparing for a picnic with your friends and need to shop for supplies, including cups and utensils. At the store you notice that there are options other than the usual disposable plastic picnicware that you typically find. Some of the items are labeled as being made of "bioplastic." The packaging advertises that these products are "Eco Friendly," "Compostable," and "Made From Renewable Resources."

All these product labels leave you perplexed. What is this new material? Is it better for the environment than common plastic? You decide to find out more about bioplastic before making your purchase. What factors should you consider in order to make an informed decision when you return to the store to make your purchase?

▶ Connect to the BIGIDEA As you read about the skills and methods used in chemistry, think about how they can apply to your everyday decision making.

Introduce the Chapter

CONNECTIONS TO EVERYDAY LIFE Students often question whether the subjects they study in school relate to them. Use the activity to help students understand ways chemistry is important in their everyday lives.

Activity Set up stations with different items: (1) a cup of water, powdered drink mix, and a spoon; (2) a flashlight; (3) a candle, a match with a matchbox; and (4) a sliced apple that is turning brown. Assign a student to each station. As the class watches, have the student at Station 1 stir the drink mix into the water. **Ask** What do you think chemistry has to do with the drink mix? *(Sample answers: Chemistry explains how the substances mix. Chemistry is responsible for the color and the flavor.)* Have the student at Station 2 turn the flashlight on and off and then remove the batteries. **Ask** What do you think the flashlight and batteries have to do with chemistry? *(Sample answer: Chemistry explains how the batteries provide charge to the flashlight.)* Continue to follow the same process at the other two stations, asking how chemistry relates to the items. If time allows, have students choose other items in the classroom and discuss possible connections to chemistry.

UbD

Understanding by Design

Students are building toward an understanding of matter, its properties, and its changes using problem solving in chemistry.

PERFORMANCE GOALS At the end of Chapter 1, students will be able to answer the essential questions by applying their knowledge of the scope of chemistry. Students will also be able to follow a step-by-step process when solving chemistry problems.

ESSENTIAL QUESTIONS Read the essential questions aloud. **Ask** Why is it important to study so many different subjects in school, even if you think that when you are older, your job may not use every subject? *(Sample answers: The job you eventually have may sometimes require an understanding of seemingly unrelated subjects. The knowledge you gain will help you understand the world around you.)* **Ask** Why is it useful to learn problem-solving skills? *(Sample answer: Learning how to think about problems and sometimes learning step-by-step approaches will help you solve problems you have never seen before.)*

BIGIDEA Use the photo of the chemist at work to help students connect to the concepts they will learn in this chapter. Activate prior knowledge by asking students if they have ever made something that required reading instructions, such as building a model or baking a cake. **Ask** How did you know what to do? *(I followed the instructions.)* **Ask** How could you make or fix something if there were no instructions or guidelines? *(Sample answer: You would learn as much as you could about it and then determine a way to make or fix the item.)* Point out that this approach is similar to what chemists do; they launch the problem-solving method by learning as much as they can about an unknown, and then they use that information to plan experiments and draw conclusions that are useful.

CHEMYSTERY Have students read over the CHEMystery. Connect the CHEMystery to the Big Idea by explaining that all branches of science are related. Students can connect the things they learn in chemistry to their everyday lives and to other sciences they will study in school. Have students consider the steps they can take to solve the problem of which plastic picnic supplies to buy. Point out that the problem can be solved in different ways, just as most problems in science can be solved in different ways. Have students predict what some of the words mentioned in the CHEMystery paragraph mean, such as *bioplastic* and *Eco Friendly*. As a hint, tell students to think about the prefixes *bio-* and *eco-*.

LESSON 1.1

Key Objectives

- **1.1.1 EXPLAIN** why the scope of chemistry is so vast.
- **1.1.2 IDENTIFY** five traditional areas of study in chemistry.
- **1.1.3 IDENTIFY** the central themes of chemistry.

Additional Resources

Reading and Study Workbook, Lesson 1.1
Available Online or on Digital Media:
- Teaching Resources, Lesson 1.1 Review, Interpreting Graphics

PearsonChem.com

Engage

CHEMISTRY & YOU Direct students' attention to the photograph and text that open the lesson. **Ask** In what ways does society benefit from chemists looking for the positive in a perceived difficult or dangerous situation? *(Sample answers: medical discoveries, safer automobiles, healthier food products)*

Build Background

Ask students to state what immediately comes to mind when they hear the word *chemistry*. Generate a list on the board of students' responses, and categorize the named things as living or nonliving and visible or not visible. Use this activity as an introduction to matter.

IN ACADEMIC STANDARDS for SCIENCE

- Explain that the body of scientific knowledge is organized into major theories, which are derived from and supported by the results of many experiments, and allow us to make testable predictions.

1.1 The Scope of Chemistry

CHEMISTRY & YOU

Q: *Why might this creature interest you if you were a chemist?* Fugu, also known as puffer fish, is a sushi delicacy that can also be lethal. Puffer fish contain a powerful toxin that can kill an adult a few hours after ingestion. Sushi chefs who prepare fugu must be specially trained because any contamination of the toxin-free areas of the fish can be deadly. Recently this toxin has been put to good use, as scientists have discovered that a purified form of it can treat severe pain in cancer patients.

Key Questions

- *Why is the scope of chemistry so vast?*
- *What are five traditional areas of study in chemistry?*
- *What are the central themes of chemistry?*

Vocabulary

- matter
- chemistry
- organic chemistry
- inorganic chemistry
- biochemistry
- analytical chemistry
- physical chemistry
- pure chemistry
- applied chemistry

What Is Chemistry?

Why is the scope of chemistry so vast?

Look around you. This book you are reading, the chair you sit in, and the computer you use are all made of matter. Matter is the general term for all the things that can be described as materials, or "stuff." **Matter** is anything that has mass and occupies space. The trees, the water, and the buildings you see in Figure 1.1 are all examples of matter. However, you don't have to be able to see something for it to qualify as matter. The air you breathe is an example of matter that you cannot see with the naked eye.

Have you ever wondered how some creatures can survive deep in the ocean where there is no light? Why some foods taste sweet and some taste bitter? Chemistry answers these questions and the many other questions you may have about the world you live in. **Chemistry** is the study of the composition of matter and the changes that matter undergoes. **Chemistry affects all aspects of life and most natural events because all living and nonliving things are made of matter.** Chemistry is also known as the central science, because it is fundamental to the understanding of the other sciences.

Areas of Study

What are five traditional areas of study in chemistry?

The scope of chemistry is vast, so individual chemists tend to focus on one area of study. **Five traditional areas of study are organic chemistry, inorganic chemistry, biochemistry, analytical chemistry, and physical chemistry.**

Figure 1.1 Matter Around You Everything around you is made of matter. Chemistry is the study of matter and the changes that matter undergoes.
Infer *What changes in matter do you think are happening in this photo?*

Learn more about the areas of chemistry online.

Focus on ELL

1 CONTENT AND LANGUAGE Help students actively learn to pronounce and understand the lesson vocabulary by showing them various word-analysis strategies, such as identifying and translating pronounceable word parts within a word and identifying and interpreting prefixes, suffixes, and roots within multisyllabic words.

2 FRONTLOAD THE LESSON Begin the lesson by dividing the class into three groups. Assign each group of students one of the key questions, and have them rephrase their question with simpler words. For the group with Key Question 1, have students predict reasons for why chemistry is so vast. For the other two groups, have students create a main-ideas-and-details chart that the class can complete as the material is presented.

3 COMPREHENSIBLE INPUT Slowly read aloud the captions in Figures 1.1 and 1.2, emphasizing key points by altering your tone. Enhance learning of both of these concepts by setting up an outdoor activity in which students utilize their five senses.

Most chemicals found in organisms contain carbon. Therefore, organic chemistry was originally defined as the study of the carbon-based chemicals found in organisms. Today, with few exceptions, **organic chemistry** is defined as the study of all chemicals containing carbon. The study of chemicals that, in general, do not contain carbon is called **inorganic chemistry.** Many inorganic chemicals are found in non-living things, such as rocks. The study of processes that take place in living organisms is **biochemistry.** These processes include muscle contraction and digestion. The area of study that focuses on the composition of matter is **analytical chemistry.** A task that would fall into this area of chemistry is measuring the level of carbon dioxide in the atmosphere. **Physical chemistry** is the area that deals with the mechanism, rate, and energy transfer that occurs when matter undergoes a change.

The boundaries between the five areas are not firm. A chemist is likely to be working in more than one area of chemistry at any given time. For example, an organic chemist uses analytical chemistry to determine the composition of an organic chemical. Figure 1.1 shows examples of the types of research different chemists do.

Some chemists do research on fundamental aspects of chemistry. This type of research is sometimes called pure chemistry. **Pure chemistry** is the pursuit of chemical knowledge for its own sake. The chemist doesn't expect that there will be any immediate practical use for the knowledge. However, most chemists do research that is designed to answer a specific question. **Applied chemistry** is research that is directed toward a practical goal or application. In practice, pure chemistry and applied chemistry are often linked. Pure research can lead directly to an application, but an application can exist before research is done to explain how it works.

CHEMISTRY & YOU

Q: *Why would you study a puffer fish if you were a biochemist? If you were an organic chemist?*

Differentiated Instruction

LPR LESS PROFICIENT READERS Lead the students on a walk around the school or campus. Show students objects that can be used as examples to convey vocabulary or concepts in the lesson. Allow students to collect a couple of items that can be posted in their vocabulary notebooks.

ELL ELL STUDENTS The lesson includes many photographs to illustrate the concepts presented. Create short, simple descriptions about each image that students can write in their notebooks. As you work through the presentation, ask students questions that they can answer using yes/no or one- or two-word responses or by using gestures.

L3 ADVANCED STUDENTS Challenge students to conduct research on the traditional areas of study in chemistry. Encourage students to set up an interview with a chemist at a nearby college or local research laboratory. They could also search for information online. Ask students to share their research with the class.

Foundations for Reading

BUILD VOCABULARY Explain that the definition of the term *matter* is one of the definitions used in everyday conversation. Point out that for most scientific terms with common meanings, however, the scientific definitions are almost always more specific than common usage.

READING STRATEGY Have students write a summary of this lesson. Verify that the summaries answer the lesson's key questions.

Explain

What Is Chemistry?

APPLY CONCEPTS Create a two-column table on the board. Label one column *Matter* and the other column *Nonmatter*. Tell students to think of one example that falls under each column head and to write their examples in the table. Review the table with the class once all students have participated. Explain incorrect placement of examples, and clear up any confusion about students' understanding of matter.

Areas of Study

START A CONVERSATION As a class, discuss if students feel that they have any connection to chemistry in their daily lives. **Ask** What daily activities do you do that may involve a chemical process or contact with chemicals? *(Sample answers: eating, brushing teeth, doing laundry, digesting food, using makeup, wearing deodorant, riding in a car that uses gasoline)* **Ask** Can you think of four items or activities that do not involve chemistry? *(It will be hard to find any that do not; for all responses, discuss reasons why it does involve chemistry.)*

CHEMISTRY & YOU *Sample answer:* A biochemist might study how the toxin is produced. An organic chemist might study the structure of the toxin.

Answers

FIGURE 1.1 Students are most likely to note that the leaves are changing color and the dog's muscles are contracting.

Explain

Big Ideas in Chemistry

USE VISUALS Direct students to Figure 1.2 and ask for a show of hands of students who have roasted marshmallows over a campfire. Pair these students and ask them to write step-by-step directions for roasting a marshmallow; have them include a description of the characteristics of the marshmallow at each step. Have the students read or act out their directions for the class. Assess the understanding of the students who did not have to write the directions by passing out a marshmallow to each student and having them inspect it. **Ask** Why does the marshmallow change colors during roasting? *(Sample answer: When heated, some substances within the marshmallow darken.)* What about the marshmallow prevents it from initially falling off of the stick? *(Sample answer: It has a spongy, solid consistency.)* What causes the marshmallow to lose its stability on the stick after it is heated? *(Sample answer: When heated, the marshmallow slowly begins to melt.)*

Misconception Alert

Based on how the term *chemical* is used in the media, and how it is defined in most dictionaries, students may assume that the term *chemical* refers exclusively to harmful materials. Explain that the word *chemical* describes all types of matter, including life-sustaining substances, such as water and oxygen. Explain that it is not a fair assumption to think that all chemicals are dangerous. Tell students that you will alert them when potentially harmful chemicals are used in the lab.

Big Ideas in Chemistry

What are the central themes of chemistry?

This book contains many ideas in the science of chemistry. One of the goals of your course in chemistry is to help you understand these ideas so you can use them to explain real situations that you may encounter in your life, such as the one shown in Figure 1.2. Fortunately, most of the topics of interest in chemistry are connected by a relatively few organizing principles, or "big ideas." **Some of chemistry's big ideas are as follows: chemistry as the central science, electrons and the structure of atoms, bonding and interactions, reactions, kinetic theory, the mole and quantifying matter, matter and energy, and carbon chemistry.**

BIG IDEA Chemistry As the Central Science Chemistry overlaps with all of the other sciences. Many physicists, biologists, astronomers, geologists, environmental scientists, and others use chemistry in their work.

BIG IDEA Electrons and the Structure of Atoms Carbon, oxygen, and copper are all examples of elements. Elements are composed of particles called atoms, and every atom contains a nucleus and one or more electrons. The type of products obtained in a chemical reaction is largely determined by the electrons in the reacting chemicals.

BIG IDEA Bonding and Interactions Most elements exist in chemical compounds, which are collections of two or more elements held together by relatively strong attractive forces. These forces, called chemical bonds, greatly influence the properties of compounds. Weak bonds between the particles of an element or compound can also contribute to the properties of the material.

Figure 1.2 Big Ideas
The big ideas in chemistry can help you understand the world around you. For example, all matter is made up of atoms, which are held together in compounds by chemical bonds. The fire is a result of a chemical reaction between the carbon-containing compounds in the wood and the oxygen in the air. The fire gives off energy in the form of heat and light. The gas particles in the air around the fire begin to move faster as the air heats up.
Predict ***Marshmallows are made up of mostly sugar, a carbon-containing compound. What do you think happens when the sugar is heated by the fire?***

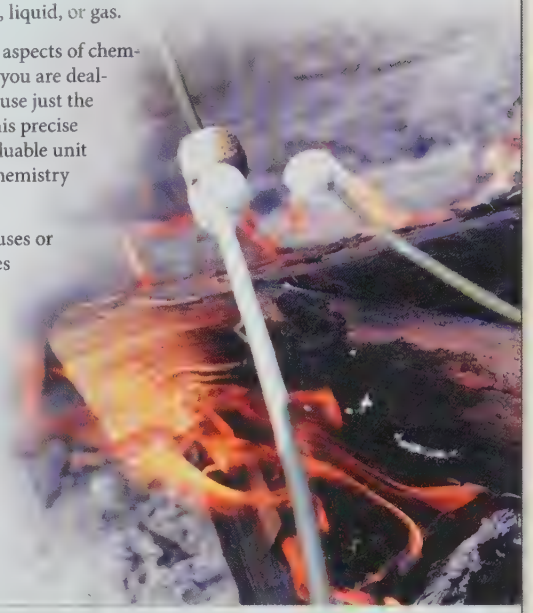
UbD Check for Understanding

BIG IDEA CHEMISTRY IS THE CENTRAL SCIENCE Write on the board the sentence below. Instruct students to copy the sentence onto a slip of paper and to fill in the blanks using words or pictures for a specific example. For struggling students, provide the hint that there are many correct answers.

One reason why chemistry is known as the central science is that it relates _____ to _____.

(Sample answers: natural science/geology; life science/medicine; volcano gases/volcano eruption; composition of stars/astronomy; illness/medicine; materials of science/safety)

ADJUST INSTRUCTION If students are having difficulty with this concept, have students reread the last sentence of the What is Chemistry? section and apply it to Figure 1.1.



BIG IDEA Reactions Chemical reactions involve processes in which reactants produce products. When you strike a match, the compounds in the head of the match combine with oxygen in the air to produce a flame. New compounds, along with light and heat, are formed. The compounds in the match head and oxygen are the reactants, and the new compounds are the products. Chemical reactions are important to the chemistry of living and nonliving things.

BIG IDEA Kinetic Theory The particles in matter are in constant motion. The ways in which these motions vary with changes in temperature and pressure determine whether a substance will be a solid, liquid, or gas.

BIG IDEA The Mole and Quantifying Matter In many aspects of chemistry, it is vital to know the amount of material with which you are dealing. In conducting a chemical reaction, you would want to use just the right amount of the reacting material so none is wasted. This precise measurement is possible using the mole, the chemist's invaluable unit for specifying the amount of material. Other concepts in chemistry also rely on the mole unit.

BIG IDEA Matter and Energy Every chemical process uses or produces energy, often in the form of heat. The heat changes that occur in chemical reactions are easy to measure. Changes in a quantity called free energy allow you to predict whether a reaction will actually occur under the given conditions.

BIG IDEA Carbon Chemistry There are about 10 million carbon-containing compounds, with new ones being prepared each day. Many of these compounds, including plastics and synthetic fibers, are produced from petroleum. Carbon compounds are the basis of life in all living organisms.

1.1 LessonCheck

1. **Explain** Why does chemistry affect all aspects of life and most natural events?
2. **List** Name the five traditional areas into which chemistry can be divided.
3. **Review** What are the "big ideas" of chemistry?
4. **Describe** What is the relationship between pure and applied chemistry?
5. **Infer** Why might a geologist ask an analytical chemist to help identify the minerals in a rock?
6. **Apply Concepts** Workers digging a tunnel through a city find some ancient pots decorated with geometric designs. Which of the following tasks might they ask a chemist to do? Explain.
   a. Determine the materials used to make the pots.
   b. Explain what the designs on the pots represent.
   c. Recommend how to store the pots to prevent further damage.

BIG IDEA CHEMISTRY AS THE CENTRAL SCIENCE

7. Why would a student who wants to be a doctor need to study chemistry?

Lesson Check Answers

1. Living and nonliving things are made of matter, and chemistry is the study of matter.
2. organic chemistry, analytical chemistry, biochemistry, physical chemistry, and inorganic chemistry
3. chemistry as the central science; electrons and the structure of atoms; bonding and interactions; reactions; kinetic theory; the mole and classifying matter; matter and energy, carbon chemistry
4. Pure research can lead directly to an application; an application can exist before research is done to explain how it works.
5. An analytical chemist focuses on the composition of matter.
6. a and c
7. **BIG IDEA** *Sample answer:* A doctor needs to understand reactions that take place in the body as well as factors that can interfere with these processes.

Extend

Connect to MEDICINE

Point out that medicine is one discipline which often relies on applied chemistry. Tell students that one area of medical interest is the use of animal venom as a source of therapeutic drugs. Challenge students to research vampire bats, death stalker scorpions, cone snails, or poison dart frogs to learn about recent discoveries. Have students present to the class the reasons why their animal produces venom and the properties of the venom that sparked the interest in medical research. Students should also be prepared to discuss the successes and failures of the research and show how this type of research exemplifies the Big Idea of chemistry being the central science.

Evaluate

Informal Assessment

Assess students' understanding of the science of chemistry by asking them to define *chemistry* in their own words. *(Chemistry is the study of the composition of matter and the changes it undergoes.)* **Ask** What do chemists do? *(Chemists study the composition and behavior of matter.)* Then have students complete the 1.1 Lesson Check.

Reteach

Direct students' attention to Figure 1.2. Beginning with the Big Idea that chemistry is a central science, challenge students to identify why this photograph illustrates each Big Idea. For example, explain that this photograph illustrates that chemistry is the central science because food scientists used chemistry to develop the recipe for the marshmallows, and textile scientists used chemistry to develop the dyes in the clothes.

Answers

FIGURE 1.2 Students are likely to say that the sugar reacts. (Some students may know that caramel forms when sugar is heated.)

LESSON 1.2

Key Objectives

1.2.1 IDENTIFY three general reasons to study chemistry.

1.2.2 IDENTIFY some outcomes of modern research in chemistry.

Additional Resources

Reading and Study Workbook, Lesson 1.2

Available Online or on Digital Media:

- Teaching Resources, Lesson 1.2 Review

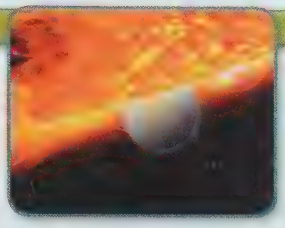
Engage

CHEMISTRY & YOU As a class, discuss past and current space exploration studies and benefits. **Ask** What do you think scientists hoped to gain by launching a telescope out of Earth's atmosphere into space? *(Sample answer: evidence of life on other planets)*



Activate Prior Knowledge

Encourage students to think of ways that technology might benefit chemical research, and vice versa. Explain that, in this lesson, they will explore the roles that chemistry plays in society and why the study of chemistry is important.

IN ACADEMIC STANDARDS for SCIENCE

- Explain how scientific knowledge can be used to guide decisions on environmental and social issues.

1.2 Chemistry and You

CHEMISTRY & YOU

Q: *How is chemistry used to study worlds other than your own?* The Hubble Space Telescope has provided detailed views of celestial objects. Scientists who know chemistry have also used the telescope to discover water and compounds containing carbon on a planet located 63 light years from Earth. Such compounds are necessary for life on Earth. However, the planet, designated HD189733b, is much too hot to support life. Perhaps the Hubble Space Telescope or its successors will someday be used to find evidence of life on planets with atmospheres more like that of Earth.

Key Questions

- ***What are three general reasons to study chemistry?***
- ***What are some outcomes of modern research in chemistry?***

Vocabulary

- technology

Figure 1.3 Chemistry and Food
When cut apples are exposed to air, a chemical reaction takes place, which causes the color to change to brown.

Why Study Chemistry?

What are three general reasons to study chemistry?

You may not realize it, but chemistry can answer many questions you have about the world around you. Should you use hot water or cold water to remove a grass stain from a shirt? How could you prepare for a career in nursing, firefighting, or journalism? If your local government wanted to build a solid waste incinerator in your town, what questions would you ask about the project? **Chemistry can be useful in explaining the natural world, preparing people for career opportunities, and producing informed citizens.**

Explaining the Natural World You were born with a curiosity about your world. Chemistry can help you satisfy your natural desire to understand how things work. For example, chemistry can be seen in all aspects of food preparation. Chemistry can explain why cut apples, such as the one shown in Figure 1.3, turn brown upon exposure to air. It can explain why the texture of eggs changes from runny to firm as eggs are boiled. Chemistry can explain why water expands as it freezes, why sugar dissolves faster in hot water than in cold water, and why yeast makes bread dough rise. After you study this textbook, you will know the answers to these questions and many more.

Preparing for a Career Being a chemist can be rewarding. Chemists contribute to society in many ways. In this book, you will find features on careers that require knowledge of chemistry. Some of the choices may surprise you. You do not need to have the word *chemist* in your job title to benefit from understanding chemistry. For example, a reporter may be asked to interview a chemist to gather background for a story. Turf managers have the important task of keeping the grass on golf courses, lawns, and soccer fields, such as the one shown in Figure 1.4a, healthy. This job requires an understanding of soil chemistry. Figure 1.4b shows a firefighter, who must know which chemicals to use to fight different types of fires.

Focus on ELL

1 CONTENT AND LANGUAGE Ask students to state the key questions in their own words. Explain that the wording of each question indicates that both questions will have more than one answer. Then, have students locate the boldfaced answers to each question. Show students that commas are used to separate the series of answers to each question in a single sentence. Demonstrate how to rewrite each answer series as a numbered list that can be used as the framework for an outline.

2 FRONTLOAD THE LESSON Have students take a picture walk through the lesson, and ask students to identify any visual displays that they find difficult to read or interpret. Use Figure 1.6 to explain how to read a graph.

3 COMPREHENSIBLE INPUT Stage a debate on the pros and cons of polylactic acid (PLA) plastics. Divide the class into two groups of mixed proficiency: one for PLA and one against PLA. Prior to the debate, have each group create drawings to depict entries in the table on page 9 that reflect the group's position and to use as visual aids.

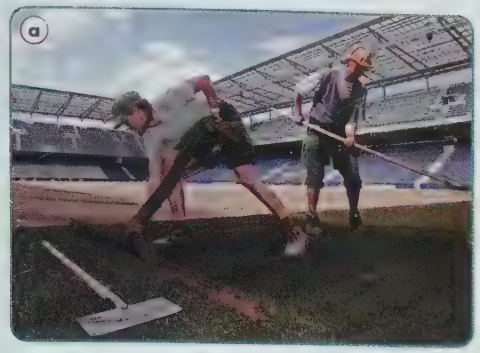


Figure 1.4 Careers
Many careers require a knowledge of chemistry. **a.** Turf managers must know how the soil and other conditions affect grass. **b.** Firefighters must choose the correct chemicals to extinguish different types of fires.
Infer ***What are some factors that may affect the health and appearance of the grass on a soccer field?***

Being an Informed Citizen Industry, private foundations, and the federal and state governments all provide funds for scientific research. The availability of funding can influence the direction of research. Those who distribute funds have to balance the importance of a goal against the cost. Areas of research often compete for funds because there is limited money available.

For example, space exploration research could not take place without federal funding. Critics argue that the money spent on space exploration would be better spent on programs such as cancer research. Those who support space exploration point out that NASA research has led to the development of many items used on Earth. These include smoke detectors, scratch-resistant plastic lenses, heart monitors, and flat-screen televisions. What if all the money spent on space exploration was used to find a cure for cancer? Are there enough valid avenues of research to take advantage of the extra funding? Would there be qualified scientists to do the research?

Like the citizen shown in Figure 1.5, you will need to make choices that will influence the direction of scientific research. You may vote directly on some issues through ballot initiatives or indirectly through the officials you elect. You may speak at a public hearing, write a letter to the editor, or sign a petition. When it comes to scientific research, there is no one correct answer. However, knowledge of chemistry and other sciences can help you evaluate the data presented, arrive at an informed opinion, and take appropriate action.

Figure 1.5 Voting
Through voting, citizens have a say in the decisions their government makes. Those decisions include how much money to provide for scientific research.

Differentiated Instruction

LPR LESS PROFICIENT READERS Refer students to the graph in Figure 1.6. Direct students to read the title of the graph, the *x*-axis label and scale, and the *y*-axis label and scale. Ask students to describe the pattern in the bar lengths from 1960 to 2007. Explain that a graph displays information visually rather than in words.

ELL ENGLISH LANGUAGE LEARNERS Prior to students reading the "Pros & Cons" chart on page 9, explain that *pro* is a Latin word meaning "for or on behalf of" and *con* is derived from the Latin word *contra*, meaning "against." Try using visual cues such as thumbs up and thumbs down to represent for and against.

L3 ADVANCED STUDENTS Ask students to determine if they think the growth of plastic waste in Figure 1.6 could be represented by a linear function, quadratic function, or exponential function. Ask them to explain. *(Linear function; the rate of change in the different intervals is approximately the same. The data do not show an exponential pattern but approximate a straight line.)*

Foundations for Reading

BUILD VOCABULARY As a class, brainstorm a list of words to describe technology. Guide students to use the list to paraphrase the definition of *technology*.

READING STRATEGY Have students create and use a web to visually display their answers to the key questions. Explain that a web is a flexible outline for organizing and prioritizing information.

Explain

Why Study Chemistry?

START A CONVERSATION **Ask** Why did you decide to take this chemistry course? *(Sample answers: I needed a science credit; I want to attend college; I want to be a scientist.)* **Ask** After previewing this lesson, what do you think is a benefit of studying chemistry that you did not expect when you signed up for this course? *(Sample answers: a greater appreciation for research and discovery, an awareness of technological advances, an understanding of how my actions affect the environment)*

Extend

Connect to JOURNALISM

Have students scan newspapers for current news stories related to chemistry. Have students cut out or print one article and prepare a short presentation on how the content of the article relates to chemistry.

Explore

Teacher Demo

PURPOSE To provide a visual display of how chemistry plays a role in a variety of natural processes

MATERIALS slides or computer images showing events or structures such as a volcanic eruption, a forest fire, a limestone cave and lightning.

ADVANCE PREPARATION Create a slide show of images for which you can make a connection to chemistry without having to supply details that students will study later.

PROCEDURE Run through the set of slides once without discussion. Discuss the common thread among the images. Then go through the slides a second time and explain the connection to chemistry.

Answers

FIGURE 1.4 *Sample answer:* amount of rain, amount of sunlight, amount of use of the field for practice and games

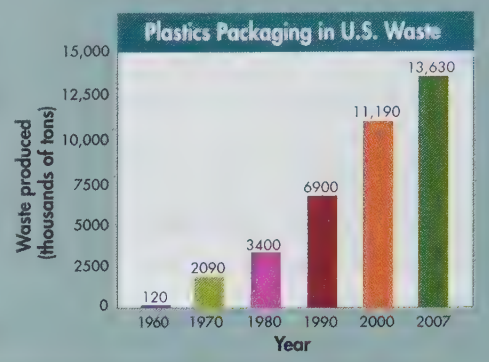
Explain

Chemistry, Technology, and Society

USE MODELS Point out that in the modern world, manufactured items often are made from materials that are created by chemists rather than those that are natural. Show students an assortment of classroom electronics, such as a computer, a calculator, and an electronic balance or pH meter. **Ask** What is similar about the construction materials used in all of these electronic devices? *(Sample answers: They are primarily made of plastic.)* **Ask** What properties of plastic make it a useful material for these electronic devices? *(Sample answers: lightweight, moldable, strong, durable, resistant to water and heat, inexpensive)*

USE VISUALS Direct students to the graph in Figure 1.6. **Ask** How much plastic waste do you think was produced prior to 1950? *(Sample answer: about half of what is shown in 1960, so about 60,000 pounds)* **Ask** What led to your conclusion? *(The value for each decade is approximately double that of the previous decade.)* **Ask** What do you think accounted for the increase of plastic waste after 1960? *(Sample answer: increased use of plastic as a material for multiple items)*

CRITICAL THINKING Refer students back to the previous conversation regarding plastics. Engage students in a discussion about the pervasiveness of plastic-encased electronics in today's society and people's tendency to upgrade their electronics at an ever-increasing rate. Encourage students to speculate on how the increase in plastic packaging waste is driven not by convenience but by human nature and the desire to have the newest and most technologically advanced products.



InterpretGraphs

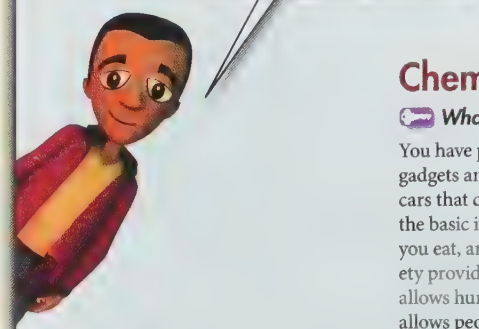


Figure 1.6 Plastics packaging includes soft-drink and water bottles, milk and water jugs, and other plastic containers.

a. Read Graphs How much plastics packaging was in U.S. waste in 2007?

b. Calculate How much more plastics packaging was in U.S. waste in 2000 than in 1990?

c. Predict Do you think that the amount of plastics packaging in U.S. waste will increase or decrease in the next 10 years? Explain.

Chemistry, Technology, and Society

What are some outcomes of modern research in chemistry?

You have probably heard the term *high tech* used when describing the latest gadgets and inventions, such as computers that are the size of your watch, or cars that can drive themselves. However, you may not realize that many of the basic items you use every day, such as the sneakers you wear or the cereal you eat, are products of technology. **Technology** is the means by which a society provides its members with those things needed and desired. Technology allows humans to do some things more quickly or with less effort. It also allows people to do things that would be otherwise impossible, such as traveling to the moon. **Modern research in chemistry can lead to technologies that aim to benefit the environment, conserve and produce energy, improve human life, and expand our knowledge of the universe.**

Materials and the Environment Chemists don't just study matter—they also use what they know about the structure and properties of matter to make new materials with different or improved properties. Take plastics, for example. If you have ever consumed bottled water, eaten a salad with a disposable fork, or put on your helmet before riding your bike, you have used plastics. Chemistry has played a large role in developing plastics for different uses.

Most plastics are made using petrochemicals, which are chemical products derived from petroleum. Although plastics are a part of most of our daily lives, there is concern that their use is taking a toll on the environment and on natural resources. The supply of petrochemicals is limited, and the manufacture of plastics uses large amounts of energy. Unrecycled plastics end up in landfills, where they remain for hundreds of years. Figure 1.6 shows the amount of plastics packaging in U.S. waste. Understandably, there has been a demand for plastics that are better for the environment. Figure 1.7 describes a new technology that offers an alternative to petroleum-based plastics.

Biodegradable Insulation

Air makes a good barrier to the movement of thermal energy as long as the air is not moving. In fiberglass, air is trapped by a network of thin fibers that are woven together. In foam insulation, the air pockets are completely enveloped by the solid that makes up the framework of the foam. SEAgel insulation is made of agar, which is derived from seaweed. A gelatin-like mixture of agar and water is freeze-dried to remove the water. What is left is a honeycomb of dried agar filled with air. SEAgel has a density approximately equal to that of air. It is also biodegradable.

Figure 1.7 Bioplastic
Polylactic acid (PLA) is known as a bioplastic. Made from corn, PLA can be used to manufacture many items that are typically made out of petroleum-based plastics, including cups, utensils, containers and packaging for food, and bags.

Pros & Cons

Advantages of PLA	Disadvantages of PLA
✔ **Made from renewable resources** PLA can be made from corn and other crops, which can be grown year after year.	✘ **Melts at low temperatures** Since PLA melts at temperatures lower than other common plastics, it doesn't have as many applications.
✔ **Less energy** The production of PLA uses less energy than the production of conventional plastics.	✘ **Made from corn** The fields used to grow corn for PLA could be used to grow food for Earth's growing population. There is also concern that the corn used to produce PLA is genetically modified.
✔ **Better for the environment** Fewer greenhouse gases, such as carbon dioxide, are produced in the production of PLA than in the production of other plastics. Also, PLA can be broken down into compounds found in nature.	✘ **Difficult to dispose of** PLA must be taken to special compost facilities in order to ensure that the material breaks down. Products made from PLA cannot be recycled with other plastics.

MAKE A CONNECTION Explain to students that composting is the disposal of food waste and plant remains that relies on aerobic decomposition to break materials down into soil-like particles. Point out that this breakdown occurs naturally when leaves pile up on the forest floor, eventually decay, and return to the soil. Because of the rich nutrients in the soil that is produced, people started using composting as a method that not only reduces the amount of garbage sent to landfills but also produces nutrient-rich soil to add to houseplants, gardens, and landscapes.

CRITICAL THINKING **Ask** In what ways will society benefit from using PLA rather than petroleum-based plastics in products? *(Sample answers: reduction of plastic in landfills, reduction of energy costs for production)* **Ask** Describe other ways in which chemistry has played a role in benefiting the environment. *(Guide students to think of energy-efficient home designs, such as green roofs, solar panels, and LED lighting.)*

UbD Check for Understanding

The Essential Question **Why is it important to study chemistry?**

Ask students to write a one-minute summary that answers this essential question.

ADJUST INSTRUCTION If students are having difficulty answering this question, have students reread the lesson. Then generate a discussion on the importance of having not only an informed citizenry but also informed and knowledgeable individuals in industry and government.

Answers

INTERPRET GRAPHS

a. 13,630,000 tons
b. 4,290,000 tons
c. *Sample answer:* It is likely to increase unless there is a dramatic change in how items are packaged.

Explain

START A CONVERSATION Discuss with students the difference between renewable energy and nonrenewable energy. Ask a volunteer to explain why the U.S. is trying to develop alternative ways to obtain energy other than oil. **Ask** What types of alternative energy do you think are most promising? *(Sample answers: solar power, nuclear power, biodiesel, wind power, hydropower, hydrogen fuel cells)* Explain to students that they will be learning more about the chemistry of nuclear power, fossil fuels, alternative fuels, and fuel cells as the year progresses.

USE VISUALS Have students study Figure 1.8. Tell students that one of the applications of this technology was a worldwide research endeavor called the Human Genome Project, which ran from 1990 to 2003. Scientists involved in this project successfully used the technology to identify and sequence the genes that make up the human genome–which totals about 30,000 genes. They also aimed to develop analytical tools that could be transferred to the private sector and address any ethical, legal, and social issues (ELSI). These developments are utilized in today's biotechnology research. The chemistry of DNA will be explored in Chapter 24.

Extend

Connect to MEDICINE

Point out that it is one thing to produce new effective medicines and medical devices and quite a different challenge to test them, get them approved, and produce them in quantity. Have students work in small groups. Tell them to research the steps involved in getting approval for a new medicine or device from the FDA and how much time is usually required. Or assign each group a prescription medication that is currently on the market and ask them to trace it backward through the approval stages.

Energy The needs of any modern society require energy to power homes, factories, and transportation. With population growth and more industrialization around the globe, the demand for energy is on the rise. There are only two ways to meet the demand for energy—conserve it or produce more of it. Chemistry plays an essential role in both of these options.

Gasoline-electric hybrid cars play a substantial role in the conservation of energy. They have greater fuel efficiencies than gasoline-powered vehicles. Hybrids use both a gasoline engine and a set of batteries to run the car. A knowledge of chemistry was necessary to develop these batteries. In an effort to produce more energy, sustainable energy sources are important to consider. Unlike fossil fuels, the sun is a renewable energy source. Chemists help design materials that collect energy from the sun that is then converted to electricity.

Medicine and Biotechnology Chemistry supplies the medicines, materials, and technology that doctors use to treat their patients. Biochemists work with biologists and doctors to understand the structure of matter found in the human body and the chemical changes that occur in cells.

There are more than 10,000 prescription drugs, which have been designed to treat various conditions including infections, high blood pressure, and depression. Other drugs, such as aspirin and antacids, can be sold without a prescription. Many drugs are effective because they interact in a specific way with chemicals in cells. Chemists who develop these drugs must have knowledge of the structure and function of these target chemicals in order to design safe and effective drugs. Chemistry can also develop materials to repair or replace body parts. Diseased arteries can be replaced with plastic tubes. Artificial hips and knees made from metals and plastics can replace worn-out joints and allow people to walk again without pain.

Figure 1.8a shows a model of a small piece of DNA. Segments of DNA, called genes, store the information that controls changes that take place in cells. Biotechnology applies science to the production of biological products or processes. It uses techniques that can alter the DNA in living organisms. It may depend on the transfer of genes from one organism to another. When genes from humans are inserted into bacteria, the bacteria act as factories that produce chemicals of importance to humans, such as insulin. Production takes place in large versions of the bioreactors shown in Figure 1.8b.

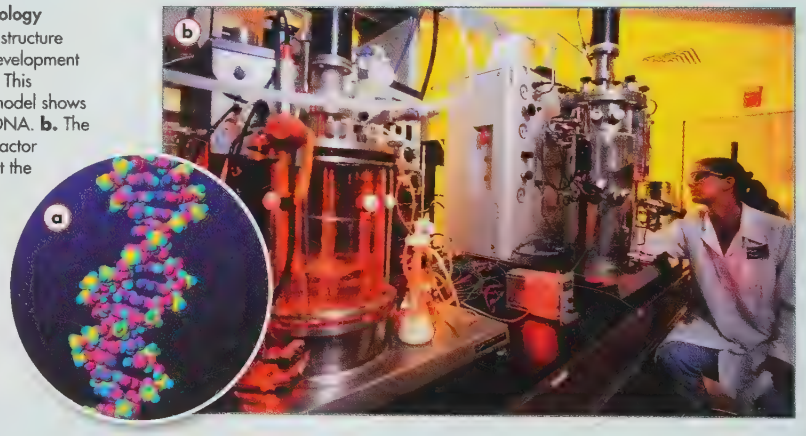

Figure 1.8 Biotechnology The discovery of the structure of DNA led to the development of biotechnology. **a.** This computer graphics model shows a small segment of DNA. **b.** The conditions in a bioreactor are controlled so that the bacteria produce as much of the product as possible.

Professional Development Note

Aspirin

In the late 1940s, Dr. Lawrence Craven observed that aspirin-containing gum, which was used to relieve pain after the removal of tonsils, caused excessive bleeding in children. He hypothesized that aspirin prevented the blood from clotting. He then began to prescribe aspirin to prevent heart attacks. In 1985, the FDA approved aspirin for patients who had suffered a heart attack. In 1996, the FDA proposed using aspirin during a suspected heart attack. In 1997, an advisory committee recommended daily low doses of aspirin for people at high risk of a heart attack. Currently aspirin is still used and recommended by doctors for this purpose.

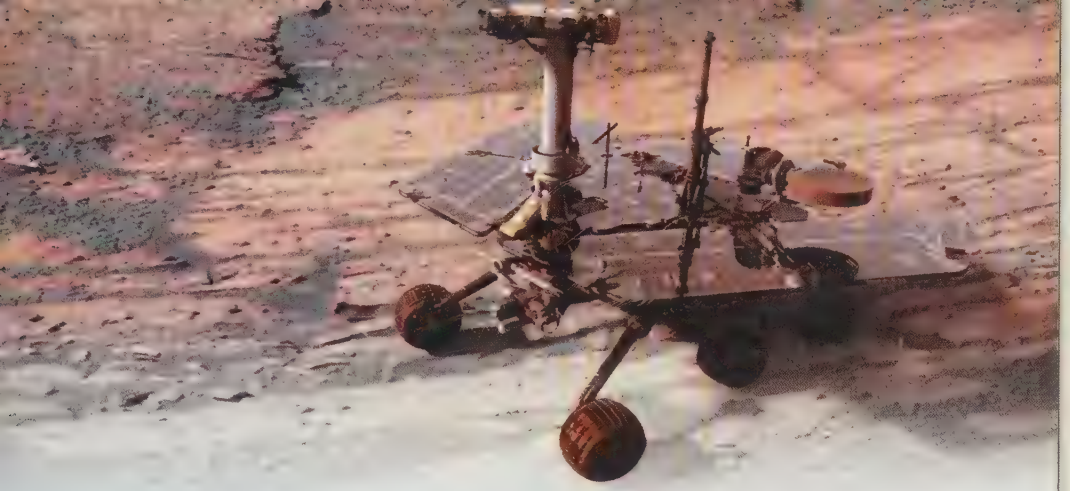

Figure 1.9 Space Exploration With help from NASA, chemists study matter from other bodies in the solar system. This drawing shows the robotic vehicle *Opportunity* on the surface of Mars.

The Universe Scientists assume that the methods used to study Earth can be applied to other objects in the universe. To study the universe, chemists gather data from afar and analyze matter that is brought back to Earth.

In the early 1800s, scientists began to study the composition of stars by analyzing the light they transmitted to Earth. In 1868, Pierre Janssen discovered a gas on the sun's surface that was not known on Earth. Joseph Norman Lockyer named the gas helium from the Greek word *helios*, meaning "sun." In 1895, William Ramsay discovered helium on Earth.

The moon and the planets do not emit light, so scientists must use other methods to gather data about these objects. The methods used depend on matter brought back to Earth by astronauts or on probes that can analyze matter in space. Chemists have analyzed more than 850 pounds of moon rocks that were brought back to Earth. The rocks were similar to rocks formed by volcanoes on Earth, suggesting that vast oceans of molten lava once covered the moon's surface. Figure 1.9 is a drawing of the robotic vehicle *Opportunity*. The vehicle was designed to determine the chemical composition of rocks and soil on Mars. Data collected at the vehicle's landing site indicated that the site was once drenched with water.

CHEMISTRY & YOU

Q: *How can chemistry be used to find evidence of life on other planets?*

1.2 LessonCheck

8. List What are three reasons for studying chemistry?

9. Review How has modern research in chemistry impacted society?

10. Describe How do chemists study the universe?

11. Form an Opinion Do the advantages of substituting the bioplastic PLA for conventional plastics outweigh the disadvantages? Would you use products made out of PLA? Why or why not?

12. Explain How can a knowledge of chemistry help you be a more informed citizen?

BIG IDEA
CHEMISTRY AS THE CENTRAL SCIENCE

13. A friend tells you that she doesn't think it is important to learn chemistry. What would be your response?

Lesson Check Answers

8. explaining the natural world, preparing for a career, being an informed citizen.

9. Students should cite some of the examples from the lesson.

10. They gather data from afar and analyze matter brought back to Earth.

11. Students should use data from Figure 1.7 to support their opinions.

12. A possible answer is that knowledge of chemistry helps a citizen evaluate data and arrive at an informed opinion about a public issue that involves technology.

13. BIG IDEA Students will likely focus on the three general reasons presented in the lesson. They may also note how central chemistry is to the friend's life.

Explore

Class Activity

Have students use the internet to locate data on the composition of the sun. Have them explain how scientists can know the composition of the sun without collecting matter from the sun. Ask students to explain why it would be difficult to present the data as a pie chart or bar graph.

CHEMISTRY & YOU Chemists can use a probe to detect evidence of water in rocks or soil; they can analyze light absorbed by a planet's atmosphere to detect water vapor.

Extend

Connect to LITERATURE

Explain to the class how public perception and expectations of science have changed dramatically over the last two hundred years. Advances in technology can lead to increased public concern about the role that science plays in shaping the future. These societal concerns are reflected in the work of 19th- and 20th-century novelists such as H. G. Wells, Edward Bellamy, Jules Verne, George Orwell, and Mary Shelley. Have students select a novel by one of these novelists and critically examine it to determine how the author addressed the role of science, technology, and society in his or her era. Students should be prepared to share their findings with the class.

Evaluate

Informal Assessment

Ask students to name examples of recent technological developments that were made possible by the study of chemistry. List the technologies on the board. Challenge students to identify whether each application benefits the environment, conserves and produces energy, improves the environment, or expands our knowledge of the universe. Then have students complete the 1.2 Lesson Check.

Reteach

Point out that being aware of the way chemistry affects the United States, other countries, and the universe will help students to better understand, benefit from, and contribute to the advances of the modern world in which they live. Ask students to generate a list of what is essential in their lives. Then have them look at their lists and determine three items that provide benefits because of chemistry.

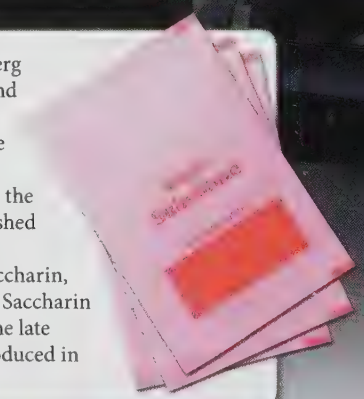
CHEMISTRY & YOU The results from an experiment do not always match the predicted outcome or hypothesis and in many cases may only lead to more questions. However, there are times that the unexpected results lead to exciting new ideas about future experiments with slightly modified variables.

Have students read the feature and take note of the corresponding photos. Point out that these examples highlight how a failed initial hypothesis resulted in products that improve everyday life. Emphasize the significance of the scientist not giving up after the "accident."

Ask What are some other uses that may have come out of these discoveries? *(Sample answers: sports balls, shoe soles, skateboard wheels, stain-resistant fabrics, lubricants, plumbing tape, no-residue tape, new artificial sweeteners, diet soda)*

CHEMISTRY & YOU: TECHNOLOGY

Accidental Chemistry

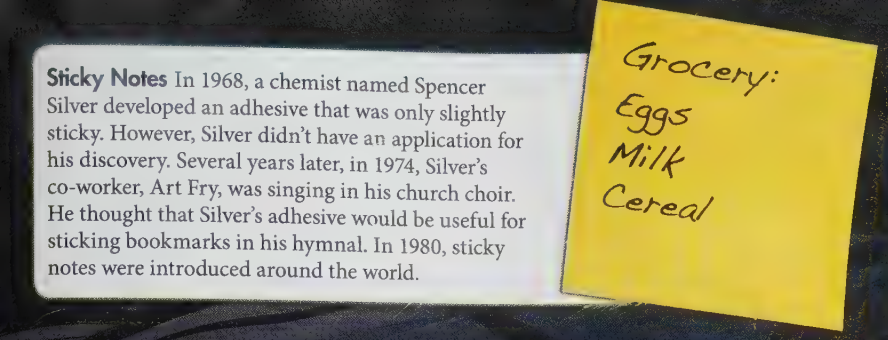


Typically, chemists direct their research toward a practical goal or application. However, sometimes scientists accidentally stumble upon a discovery that they didn't intend to find.

Polytetrafluoroethylene In 1938, Roy J. Plunkett was researching new refrigerants, which are compounds used in refrigerators and air conditioners. In preparation for an experiment, Plunkett stored a compound called tetrafluoroethylene gas (TFE) in cylinders at a low temperature overnight.

When Plunkett was ready to use the TFE the next day, he found that none of the gas came out. He opened a cylinder to find a white, waxy solid that was very slippery and did not react with any other chemicals.

The substance that Plunkett accidentally made, called polytetrafluoroethylene (PTFE) has many uses that you may be familiar with, such as insulation for electrical cables, soil and stain repellents for fabrics, and coatings for nonstick cookware.



Saccharin In 1879, Constantine Fahlberg was looking for new uses for coal tar and forgot to wash his hands after working one day in the lab. When he went home to eat dinner that night he noticed that his bread tasted sweet. He realized that the sweet taste was coming from his unwashed hands.

The substance on his hands was saccharin, which is the oldest artificial sweetener. Saccharin was initially sold in tablet form from the late 1890s to the 1940s. In 1957, it was introduced in granulated form.

21st Century Learning To be successful in the 21st century, students need skills and learning experiences that extend beyond subject matter mastery. This project helps students build the following 21st-Century Skills: *Creativity and Innovation; Communication and Collaboration; Information, Media, and Technology Literacy; Initiative and Self-Direction;* and *Social Skills.*

UNDER PRESSURE Scientists must secure funding for their research. Government and corporate financial backers require regular project updates and proof of progress before approving additional funding. Pose the following challenge to your students. They are to form research groups of three to five students each and choose one of these four experiments as the group's project. They will prepare a 15-20 minute presentation for their financial backers (the class) on the status of their project. The presentation will be made via an Internet meeting program from their "lab" (an unused classroom or computer lab). It is their job to convince the backers to continue funding their project, despite the outcome of their original research. Presentations should include a summary of the purpose of the original research, a graphic presentation of the results, a proposal for exploring the possible uses of the discovery, and a proposed budget.

Sticky Notes In 1968, a chemist named Spencer Silver developed an adhesive that was only slightly sticky. However, Silver didn't have an application for his discovery. Several years later, in 1974, Silver's co-worker, Art Fry, was singing in his church choir. He thought that Silver's adhesive would be useful for sticking bookmarks in his hymnal. In 1980, sticky notes were introduced around the world.

Vulcanized Rubber When rubber was introduced in the early 1830s, it was not very useful. It froze in the winter and melted into a glue-like substance in the summer. Charles Goodyear, a hardware merchant from Philadelphia was on a quest to improve the properties of the substance. After countless failed experiments, Goodyear began using sulfur in his rubber formulations. In the winter of 1839, a chunk of his rubber-sulfur formulation landed on top of a hot stove. Instead of melting, the rubber charred. The mixture had hardened but it was still elastic.

Thomas Hancock, an Englishman, saw a sample of Goodyear's rubber and re-invented it in 1843. He named the processes "vulcanization," after Vulcan, the Roman god of fire.

Take It Further

1. **Identify** Coal tar contains carbon. What type of chemistry was the focus of Fahlberg's research?
2. **Classify** Were the inventors in these examples performing pure or applied research when they made their discoveries? Explain.
3. **Infer** When Plunkett couldn't get the TFE gas out of the cylinders, he weighed them and found that they weighed the same as they did the night before. What was the significance of this finding?
4. **Form an Opinion** Are the inventions described examples of technology? Why or why not?

Explain

START A CONVERSATION Explore the initial disappointment the researchers must have felt by relating it to an experience in which the school, class, or student had to deal with an unexpected outcome. Ask students to consider what would have happened had the researchers simply stopped at that point, rather than continuing to experiment. **Ask** What step of the scientific method did these researchers pursue that resulted in an amazing discovery? *(They modified the initial hypothesis and designed new experiments.)*

Extend

Encourage students to identify examples of discoveries they have discussed in other science courses that could be described as "accidental". Ask students to create a timeline noting how and when one such discovery was made, and showing past and current uses, applications, or subsequent discoveries.

Connect to LANGUAGE ARTS

Have students write a factual yet humorous narrative about the way in which Sir Isaac Newton discovered gravity. Students may write from the perspective of either an unseen observer or Newton himself.

Differentiated Instruction

L1 LESS PROFICIENT READERS Display visual examples of each product, and use the images as you discuss each discovery.

ELL ENGLISH LANGUAGE LEARNERS For each of the four products shown in the pictures, have samples available for students to touch, smell, and observe.

L3 ADVANCED STUDENTS Assign students one of the four products featured, and have them generate a flowchart outlining the steps they would have expected the researcher to follow.

Answers

TAKE IT FURTHER

1. organic chemistry
2. They were doing applied chemistry because they were focused on solving a specific problem.
3. Because the mass was constant, no matter had entered the cylinder or leaked out of the cylinder.
4. They are examples of technology because they provide society with things that are useful.

LESSON 1.3

Key Objectives

1.3.1 DESCRIBE how Lavoisier transformed chemistry.

1.3.2 IDENTIFY three steps in the scientific method.

1.3.3 EXPLAIN the role collaboration and communication play in science.

Additional Resources

Reading and Study Workbook, Lesson 1.3

Available Online or on Digital Media:

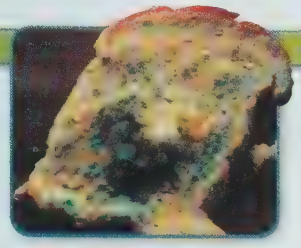
- Small-Scale Chemistry Laboratory Manual, Lab 1

PearsonChem.com

Engage

CHEMISTRY & YOU Have students study the photograph and read the text that opens the lesson. **Ask** What made Fleming different from other scientists who had seen this mold? *(Fleming recognized the importance of this discovery. He assumed that the mold had released a chemical that prevented the growth of bacteria.)*



Activate Prior Knowledge

Have students draw a T-chart in their notebooks. In the first column, they should write what they already know about the scientific method. In the second column, they should add the new information they learn as they proceed with the lesson.

IN ACADEMIC STANDARDS for SCIENCE

- Develop explanations based on reproducible data and observations gathered during laboratory investigations.
- Clearly communicate their ideas and results of investigations verbally and in written form using tables, graphs, diagrams, and photographs.

1.3 Thinking Like a Scientist

CHEMISTRY & YOU

Q: *How do you think Alexander Fleming tested his hypothesis?* In 1928, Alexander Fleming, a Scottish scientist, noticed that a bacteria he was studying did not grow in the presence of a yellow-green mold. Other scientists had made the same observation, but Fleming was the first to recognize its importance. He assumed that the mold had released a chemical that prevented the growth of the bacteria. That chemical was penicillin, which can kill a wide range of harmful bacteria.

Key Questions

- ***How did Lavoisier help to transform chemistry?***
- ***What are the steps in the scientific method?***
- ***What role do collaboration and communication play in science?***

Vocabulary

- scientific method
- observation
- hypothesis
- experiment
- independent variable
- dependent variable
- model
- theory
- scientific law

An Experimental Approach to Science

How did Lavoisier help to transform chemistry?

The word *chemistry* comes from the word *alchemy*. Long before there were chemists, alchemists were studying matter. Alchemy arose independently in many regions of the world. It was practiced in China and India as early as 400 B.C. In the eighth century, Arabs brought alchemy to Spain, and from there it spread quickly to other parts of Europe.

You may have heard that alchemists were concerned with searching for a way to change other metals, such as lead, into gold. Although alchemists did not succeed with this quest, the work they did spurred the development of chemistry. Alchemists developed the tools and techniques for working with chemicals. For example, alchemists developed processes for separating mixtures and purifying chemicals. They designed equipment that is still used today, including beakers, flasks, tongs, funnels, and the mortar and pestle, which is shown in Figure 1.10. What they did not do was provide a logical set of explanations for the changes in matter that they observed. Chemists would accomplish that task many years later.

Figure 1.10 Mortar and Pestle
Pharmacists still use a bowl-shaped mortar and club-shaped pestle to mix drugs for patients. The mortar and pestle in this photograph are made of porcelain, which is a hard material.
Infer ***What may be some other uses of a mortar and pestle?***

Focus on ELL

1 CONTENT AND LANGUAGE Preview the vocabulary terms by pronouncing each term and having students repeat it. Allow students time to add the terms to their vocabulary notebooks, with definitions, parts of speech, and examples or sketches. Encourage struggling students to add native language equivalents.

2 FRONTLOAD THE LESSON Have students preview and predict what the lesson is about by reading the first sentence of each major paragraph and looking at the visual displays. Once the lesson has been read, predictions can be confirmed or denied.

3 COMPREHENSIBLE INPUT Use Figure 1.14 to explain how to read a flowchart, and provide students with a copy of a flowchart that explains each step of the scientific method. Use the Quick Lab to model the scientific method.

By the 1500s in Europe, there was a shift from alchemy to science. Science flourished in Britain in the 1600s, partly because King Charles II was a supporter of the sciences. With his permission, some scientists formed the Royal Society of London for the Promotion of Natural Knowledge. The scientists met to discuss scientific topics and conduct experiments. The society's aim was to encourage scientists to base their conclusions about the natural world on experimental evidence, not on philosophical debates.

In France, Antoine-Laurent Lavoisier did work in the late 1700s that would revolutionize the science of chemistry. **Lavoisier helped to transform chemistry from a science of observation to the science of measurement that it is today.** To make careful measurements, Lavoisier designed a balance that could measure mass to the nearest 0.0005 gram.

One of the many things Lavoisier accomplished was to settle a long-standing debate about how materials burn. The accepted explanation was that materials burn because they contain phlogiston, which is released into the air as a material burns. To support this explanation, scientists had to ignore the evidence that metals can gain mass as they burn. By the time Lavoisier did his experiments, he knew that there were two main gases in air—oxygen and nitrogen. Lavoisier was able to show that oxygen is required for a material to burn. Lavoisier's wife Marie Anne, shown in Figure 1.11, helped with his scientific work. She made drawings of his experiments and translated scientific papers from English.

Figure 1.11 Antoine Lavoisier
This portrait of Antoine Lavoisier and his wife Marie Anne was painted by Jacques Louis David in 1788.

The Scientific Method

What are the steps in the scientific method?

Scientists have a powerful tool that they use to produce valuable results. Like all scientists, the biochemist shown in Figure 1.12 is using the scientific method to solve difficult problems. The **scientific method** is a logical, systematic approach to the solution of a scientific problem. **Steps in the scientific method include making observations, proposing and testing hypotheses, and developing theories.**

Making Observations

The scientific method is useful for solving many kinds of problems. Suppose you try to turn on a flashlight and you notice that it does not light. When you use your senses to obtain information, you make an **observation.** An observation can lead to a question: What is wrong with the flashlight?

Figure 1.12 Observing With a Microscope
Observation is an essential step in the scientific method.

Professional Development Note

How Oxygen Got Its Name

The ancient Greeks thought that flammable objects contained the element fire, which George Stahl (1660–1734) named *phlogiston*. During burning, phlogiston transferred to the air. Phlogiston-rich air, now called nitrogen, did not support burning; objects burned brightly in phlogiston-poor air.

Lavoisier measured the mass of metals before and after heating in a closed container. He showed that the mass gained by the metal was lost by the air. Thus, the process of burning involved a gain of matter, not a loss of phlogiston. Lavoisier named the portion of air that supported combustion oxygen.

Foundations for Reading

BUILD VOCABULARY When discussing the two types of variables, explain that one meaning of *manipulate* is "to manage or control" and one meaning of *respond* is "to answer or act in turn."

Explain

An Experimental Approach to Science

MAKE A CONNECTION Students often think that an experiment is a failure if they do not get the expected or right results. As students perform experiments, help them analyze results that do not fit a hypothesis or vary widely from those of other students. Often, you can identify experimental errors that explain deviation. Also point out that scientists can gain important insights from "failed" experiments.

Explore

Class Activity

PURPOSE Students make hypotheses based on a set of observations.

MATERIALS phenolphthalein, 70% solution of 2-propanol, small artist's paintbrush, sheets of copy paper or white butcher paper, household glass cleaner containing ammonia

ADVANCE PREPARATION Prepare a solution of phenolphthalein in alcohol (250 mg of phenolphthalein in 250 mL of 70% 2-propanol). Use the brush to letter messages on sheets of paper. Try messages such as "CHEM-IS-TRY" and "This is a LABOR-atory, not a lab-ORATORY." Allow the paper to dry until the messages are invisible. Then post the messages around the room in well-ventilated areas.

PROCEDURE At intervals, spray each sheet with the glass cleaner. Ask students to hypothesize why the pink messages appear, disappear after a few minutes, and then reappear when the paper is sprayed again.

EXPECTED OUTCOME Students are likely to infer that something in the cleaner caused a reversible change to something on the paper. They may infer that the material in the cleaner is volatile.

Answers

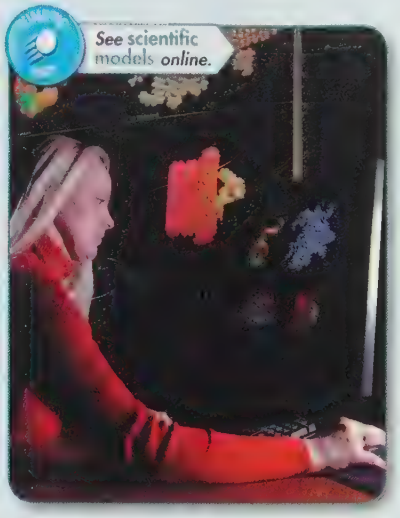
FIGURE 1.10 *Sample answers:* to grind herbs, grains, or other food items; to grind pigments for homemade oil paints or watercolors

Explain

The Scientific Method

USE VISUALS Direct students to Figure 1.14 and discuss each step. Then discuss how the steps in the scientific method allow scientists to support theories. Ask students to explain why they think some pathways in the flowchart are cyclic rather than straight. *(Cyclic pathways occur where steps may occur more than once, as with the processes of developing hypotheses and conducting experiments to test them.)*

Misconception Alert



Students may think the steps in the scientific method must be done in a particular order every time. Guide students to understand that the steps may or may not be repeated, depending on the problem.

Extend

Connect to MEDICINE

The story of how Augusto and Michaela Odone, on their own, developed an oil that relieved the symptoms of adrenoleukodystrophy (ALD)—an inherited neurological disease afflicting their son—is an excellent example of "ordinary people" applying the scientific method. This story is told in the movie *Lorenzo's Oil*. Rent or borrow a copy of the movie. Ask students to take notes as they watch the movie on how the Odones use observations, hypotheses, and experiments to help their son.

Figure 1.13 Computer Models
This scientist is using a computer to model complex molecules, which are difficult to study with experiments alone.

Testing Hypotheses If you guess that the batteries in the flashlight are dead, you are making a hypothesis. A **hypothesis** is a proposed explanation for an observation. You can test your hypothesis by putting new batteries in the flashlight. Replacing the batteries is an **experiment,** a procedure that is used to test a hypothesis. If the flashlight lights, you can be fairly certain that your hypothesis was true. What if the flashlight does not work after you replace the batteries? A hypothesis is useful only if it accounts for what is actually observed. When experimental data does not fit a hypothesis, the hypothesis must be changed. A new hypothesis might be that the light bulb is burnt out. An experiment to test this new hypothesis is to replace the bulb.

When you design experiments, you deal with variables, or factors that can change. The variable that you change during an experiment is the **independent variable,** also called the manipulated variable. The variable that is observed during the experiment is the **dependent variable,** also called the responding variable. If you keep other factors that can affect the experiment from changing during the experiment, you can relate any change in the dependent variable to changes in the independent variable. For the results of an experiment to be accepted, the experiment must produce the same result no matter how many times it is repeated, or by whom. This is why scientists are expected to publish a description of their procedures along with their results.

Sometimes the experiment a scientist must perform to test a hypothesis is difficult or impossible. For example, atoms and molecules, which are some of the smallest units of matter, cannot be easily seen. In these situations, scientists often turn to models to gain more understanding of a problem. A **model** is a representation of an object or event. Figure 1.13 shows a scientist working with computer models of complex biological molecules. Chemists may also use models to study chemical reactions and processes.

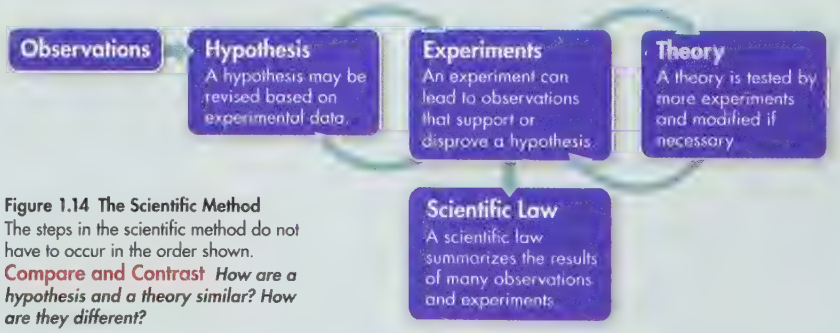


Figure 1.14 The Scientific Method
The steps in the scientific method do not have to occur in the order shown.
Compare and Contrast ***How are a hypothesis and a theory similar? How are they different?***

Differentiated Instruction

L1 STRUGGLING STUDENTS Explain to students that if they make a mistake in the lab, the scientific method allows them to repeat their experiments as many times as needed, as long as they record their work.

ELL ENGLISH LANGUAGE LEARNERS Have English learners work with a partner to describe, act out, or illustrate in a drawing the different steps that make up the scientific method. Challenge students to identify how they used each step to solve problems in the past.

L3 ADVANCED STUDENTS Have students state the constants, the independent variable, and the dependent variable in the Quick Lab experiment.

Developing Theories Figure 1.14 shows how the steps of the scientific method fit together. Once a hypothesis meets the test of repeated experimentation, it may be raised to a higher level of ideas. It may become a theory. A **theory** is a well-tested explanation for a broad set of observations. Some of the theories in chemistry are very useful because they help you form mental pictures of objects or processes that cannot be seen. Other theories allow you to predict the behavior of matter.

When scientists say that a theory can never be proved, they are not saying that a theory is unreliable. They are simply leaving open the possibility that a theory may need to be changed at some point in the future to explain new observations or experimental results.

Scientific Laws Figure 1.14 shows how scientific experiments can lead to laws as well as theories. A **scientific law** is a concise statement that summarizes the results of many observations and experiments. In Chapter 14, you will study laws that describe how gases behave. One law describes the relationship between the volume of a gas in a container and its temperature. If all other variables are kept constant, the volume of the gas increases as the temperature increases. The law doesn't try to explain the relationship it describes. That explanation requires a theory.

CHEMISTRY & YOU

Q: *What was Alexander Fleming's hypothesis? How could he test his hypothesis?*

Quick Lab

Bubbles!

Purpose To test the hypothesis that bubble making can be affected by adding sugar or salt to a bubble-blowing mixture

Materials

- 3 plastic drinking cups
- measuring cup and spoons
- liquid dish detergent
- water
- table sugar
- table salt
- drinking straw

Procedure

1. Label three drinking cups 1, 2, and 3. Measure and add one teaspoon of liquid dish detergent to each cup.
2. Use the measuring cup to add two-thirds cup of water to each drinking cup. Then swirl the cups to form a clear mixture. **CAUTION** *Wipe up any spills immediately so that no one will slip and fall.*
3. Add a half teaspoon of table sugar to cup 2 and a half teaspoon of table salt to cup 3. Swirl each cup for one minute.
4. Dip the drinking straw into cup 1, remove it, and blow gently into the straw to make the largest bubble you can. Practice making bubbles until you feel you have reasonable control over your bubble production.
5. Repeat Step 4 with the mixtures in cups 2 and 3.

Analyze and Conclude

1. **Observe** Did you observe any differences in your ability to produce bubbles using the mixtures in cup 1 and cup 2?
2. **Observe** Did you observe any differences in your ability to produce bubbles using the mixtures in cup 1 and cup 3?
3. **Draw Conclusions** What can you conclude about the effects of table sugar and table salt on your ability to produce bubbles?
4. **Design an Experiment** Propose another hypothesis related to bubble making. Design an experiment to test your hypothesis.

Focus on ELL

4 LANGUAGE PRODUCTION Have students work in groups of four to complete the lab. Make sure each group has ELLs of varied language proficiencies so that more proficient students can help less proficient ones. Have students work according to their proficiency level.

BEGINNING: LOW/HIGH Model this lab and use student volunteers to help with each step. For example, ask one student to label the cups and another student to pour the detergent.

INTERMEDIATE: LOW/HIGH Provide a picture for each step of the procedure to depict what is supposed to be done. Provide a chart for answering questions 1-4.

ADVANCED: LOW/HIGH Ask students to compare and contrast the use of salt and sugar for making bubbles.

CHEMISTRY & YOU Fleming's hypothesis was that mold released a chemical that prevented the growth of bacteria. He could test his hypothesis with other types of bacteria to see if the mold had the same affect on them.

Explore

QuickLab

OBJECTIVE By completing this activity, students will be able to test the hypothesis that bubble making can be affected by adding sugar or salt to the bubble-blowing mixture.

PREP TIME 5 minutes

CLASS TIME 15 minutes

SAFETY Remind students to be careful not to draw any liquid into their mouth through the straw.

EXPECTED OUTCOME Students conclude that sugar has no effect on bubble production and that salt prevents bubble production.

ANALYZE AND CONCLUDE

1. no
2. Yes; no bubbles formed from the liquid in cup 3.
3. Sugar has no effect on bubble production, but salt stops it completely.
4. Answers might include examining the effect of temperature or dilution of the bubble-making mixture. For example, diluting the mixture can reverse the salt effect.

FOR ENRICHMENT Facilitate a class discussion about the experiments that students proposed for Question 4. Discuss whether or not the experiments will work. Perform two of the experiments and discuss the results. Emphasize the need to learn from "failed" experiments.

Answers

FIGURE 1.14 A hypothesis and a theory are both explanations. A hypothesis is only a proposed explanation; a theory is a well-tested explanation for a broad set of observations. When a hypothesis meets the test of repeated experimentation, it may be become a theory.

Explain

Collaboration and Communication

CRITICAL THINKING Explain that students can learn about research from news reports, from specialized journals, and from the Internet. The more reliable information people have, the better able they are to effectively address public issues related to science and technology. Stress that students should not avoid reading about science, but they should look for reliable sources and approach the news with a certain amount of healthy skepticism. **Ask** How can the Internet help people learn about advances in science? *(Anyone can access information on the Internet.)* **Ask** What is one disadvantage of getting information from the Internet? *(The information is not always reliable.)* Note that sites with *.gov, .edu,* and *.org* domains are usually the most reliable sources, especially those sites that are maintained by federal and state science agencies, colleges and universities, and professional organizations.

Have students conduct an Internet search on a scientific topic of their choice and print the first page of the results. Demonstrate how to locate information to verify a site's credibility, such as professional affiliations or expert contributors or authors. Then, have students check each source on their printout and note whether they believe the site to be a reliable or unreliable source of scientific information.

Extend

Have students use the Internet to research examples of successful collaborative projects that involved a multidisciplinary approach to solving a scientific problem. For instance, the series of NASA missions to the moon in the 1970s was a collaborative project. Have students orally report their findings to the class; tell students to be prepared for questions.

Figure 1.15 Teamwork
For a volleyball team to win, the players must work together.

Collaboration and Communication

What role do collaboration and communication play in science?

No matter how talented the players on a team may be, one player cannot ensure victory for the team. Individuals must collaborate, or work together, for the good of the team. Think about the volleyball players in Figure 1.15. In volleyball, the person who spikes the ball depends on the person who sets the ball. Unless the ball is set properly, the spiker will have limited success. Many sports recognize the importance of collaboration by keeping track of assists. During a volleyball game, the players also communicate with one another so it is clear who is going to do which task. Strategies that are successful in sports can work in other fields, such as science. **When scientists collaborate and communicate with one another, they increase the likelihood of a successful outcome.**

Collaboration Scientists choose to collaborate for different reasons. For example, some research problems are so complex that no one person could have all the knowledge, skills, and resources to solve the problem. It is often necessary to bring together individuals from different disciplines. Each scientist will typically bring different knowledge and, perhaps, a different approach to a problem. Just talking with a scientist from another discipline may provide insights that are helpful.

There may be a practical reason for collaboration. For example, an industry may give a university funding for pure research in an area of interest to the industry. Scientists at the university get the equipment and financing required to do the research. In exchange, the scientists provide ideas and expertise. The industry may profit from its investment by marketing applications based on the research.

Collaboration isn't always a smooth process. Conflicts can arise about use of resources, amount of work, who is to receive credit, and when and what to publish. Like the students in Figure 1.16, you will likely work in pairs or on a team in the laboratory. If so, you may face some challenges. However, you can also experience the benefits of a successful collaboration.

Figure 1.16 Lab Partners
Working in pairs or in a group can be challenging, but it can also be rewarding.
Apply Concepts ***What steps in the scientific method are these students using?***

UbD Check for Understanding

What role do collaboration and communication play in science?

Assess students' understanding of the roles of collaboration and communication in science by asking for thumbs-up or thumbs-down gestures in response to the statement *I understand the importance of collaboration and communication in science and can explain it.*

ADJUST INSTRUCTION If students use a thumbs-down response, ask students to identify what aspects of collaboration or communication are unclear. Provide a targeted review of those aspects with students.

18 Chapter 1 • Lesson 3

Communication The way scientists communicate with each other and with the public has changed over the centuries. In earlier centuries, scientists exchanged ideas through letters. They also formed societies to discuss the latest work of their members. When societies began to publish journals, scientists could use the journals to keep up with new discoveries.

Today, many scientists, like those in Figure 1.17, work as a team. They can communicate face to face. They also can exchange ideas with other scientists by e-mail, by phone, and at local and international conferences. Scientists still publish their results in scientific journals, which are the most reliable source of information about new discoveries. Most journals are now published online and are readily accessible. Articles are published only after being reviewed by experts in the author's field. Reviewers may find errors in experimental design or challenge the author's conclusions. This review process is good for science because work that is not well founded is usually not published.

The Internet is a major source of information. One advantage of the Internet is that anyone can get access to information. One disadvantage is that anyone can post information on the Internet without first having that information reviewed. To judge the reliability of information you find on the Internet, you have to consider the source. This same advice applies to articles in newspapers and magazines or the news you receive from television. If a media outlet has a reporter who specializes in science, chances are better that a report will be accurate.

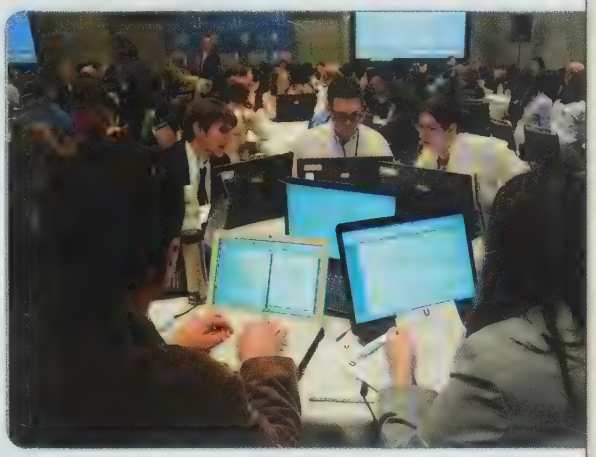

Figure 1.17 Communication Scientists often get together at professional meetings and workshops to discuss their findings and share ideas.

1.3 LessonCheck

14. Review How did Lavoisier revolutionize the science of chemistry?

15. List Name three steps in the scientific method.

16. Explain Why are collaboration and communication important in science?

17. Describe What did alchemists contribute to the development of chemistry?

18. Explain How did Lavoisier's wife help him to communicate the results of his experiments?

19. Describe What process takes place before an article is published in a scientific journal?

20. Explain Why is it important for scientists to publish a description of their procedures along with the results of their experiments?

21. Infer Why should a hypothesis be developed before experiments take place?

22. Compare What is the difference between a theory and a hypothesis?

23. Classify In Chapter 2, you will learn that matter is neither created nor destroyed in any chemical change. Is this statement a theory or a law? Explain your answer.

BIG IDEA
CHEMISTRY AS THE CENTRAL SCIENCE

24. Do the steps in the scientific method always need to be followed in order? Explain.

Evaluate

Informal Assessment

Ask students to identify an everyday type of problem that could potentially be solved by the scientific method. Then have them explain how they would use the scientific method to solve that problem. Then have students complete the 1.3 Lesson Check.

Reteach

Students may mistakenly infer that a theory grows into a law by constant testing and refinement. Or they may confuse a theory with a hypothesis. A hypothesis differs from a theory in that a hypothesis can be formed on the basis of a single set of observations. It cannot become a theory unless it explains a broad set of observations obtained from repeated experimentation. Remind students that theories can, and do, change as new information becomes available through experimentation.

Answers

FIGURE 1.16 testing a hypothesis and making observations

Lesson Check Answers

14. He helped transform chemistry from a science of observation to a science of measurement.

15. *Sample answers:* making observations, testing hypotheses, and developing theories

16. They help increase the likelihood of a successful outcome.

17. They developed the tools and techniques for working with chemicals.

18. She made drawings of his experiments and translated scientific papers.

19. Articles are reviewed by experts in the author's field of research.

20. so that other scientists can repeat the experiments and confirm the results

21. It guides the design of the experiments.

22. A theory is a well-tested explanation of a broad set of observations; a hypothesis is a proposed explanation for an observation.

23. A law; it is not an explanation.

24. BIG IDEA *Sample answer:* No; for example, most experiments do not lead directly to the development of or revision of a theory.

SMALL-SCALE LAB

Explore

Small-Scale Lab

OBJECTIVE After completing this activity, students will be able to demonstrate their knowledge of safe laboratory practices.

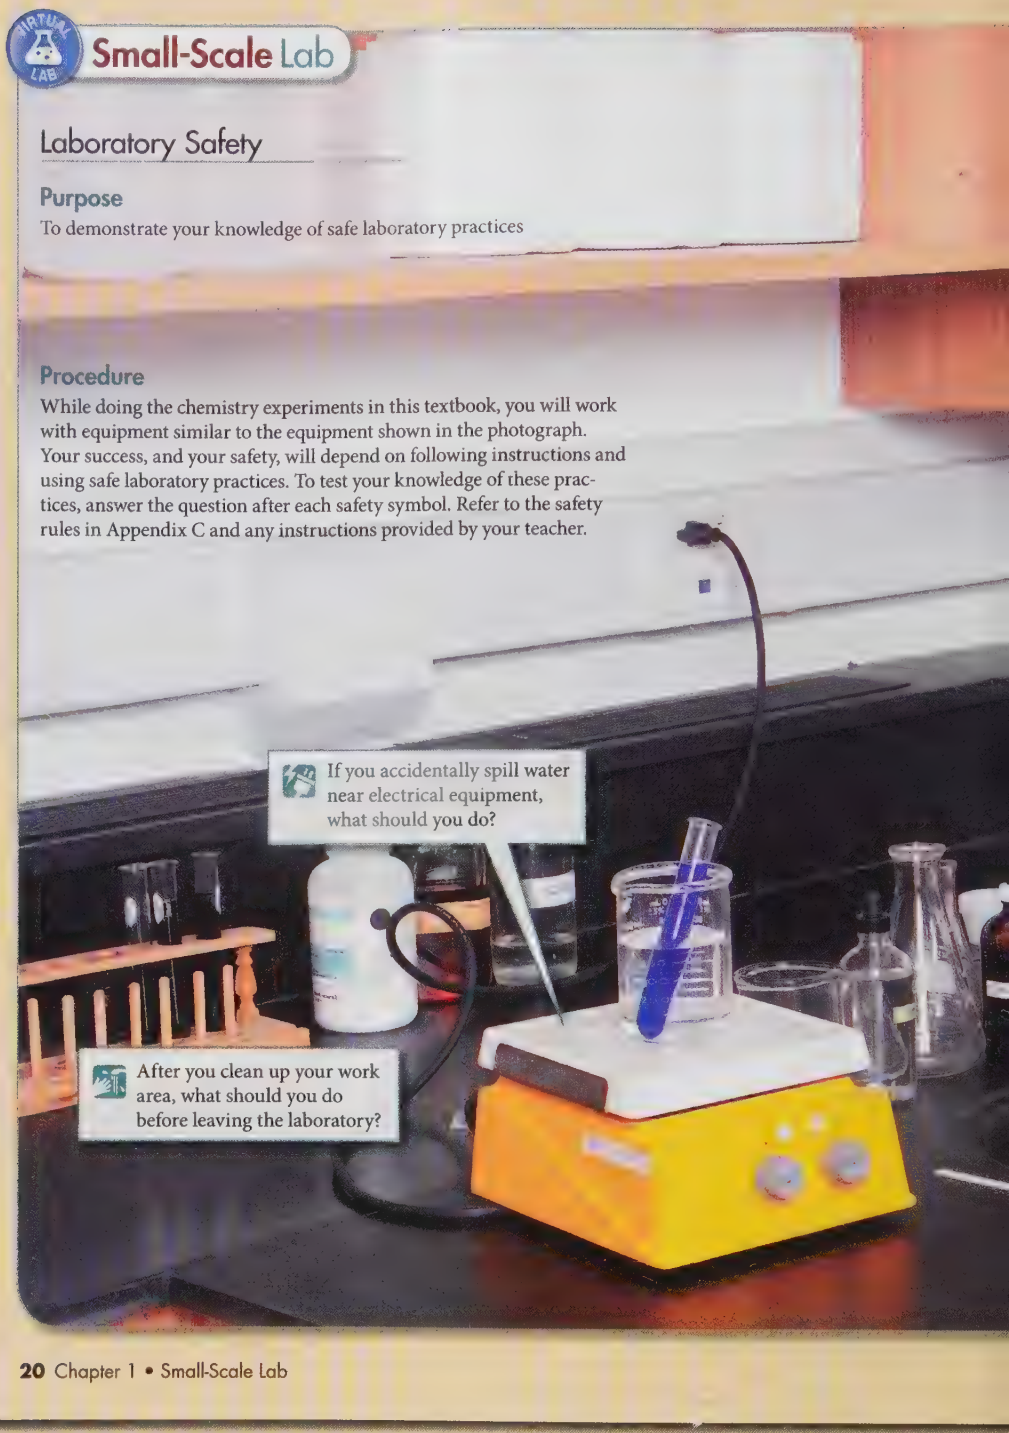
CLASS TIME 40 minutes

SKILLS FOCUS Observing, communicating results

TEACHING TIPS Students need to read Appendix C to answer the questions in the lab. Use this activity as part of an orientation in which you present your rules for working in the laboratory. Provide a floor plan of the room and have students record the location of safety equipment such as an eyewash fountain or a fire extinguisher. After you discuss the safety rules, have students sign a safety contract. For an example, see the safety contract for the small-scale chemistry labs.

ANSWERS TO QUESTIONS

Stand back, notify your teacher, and warn other students.



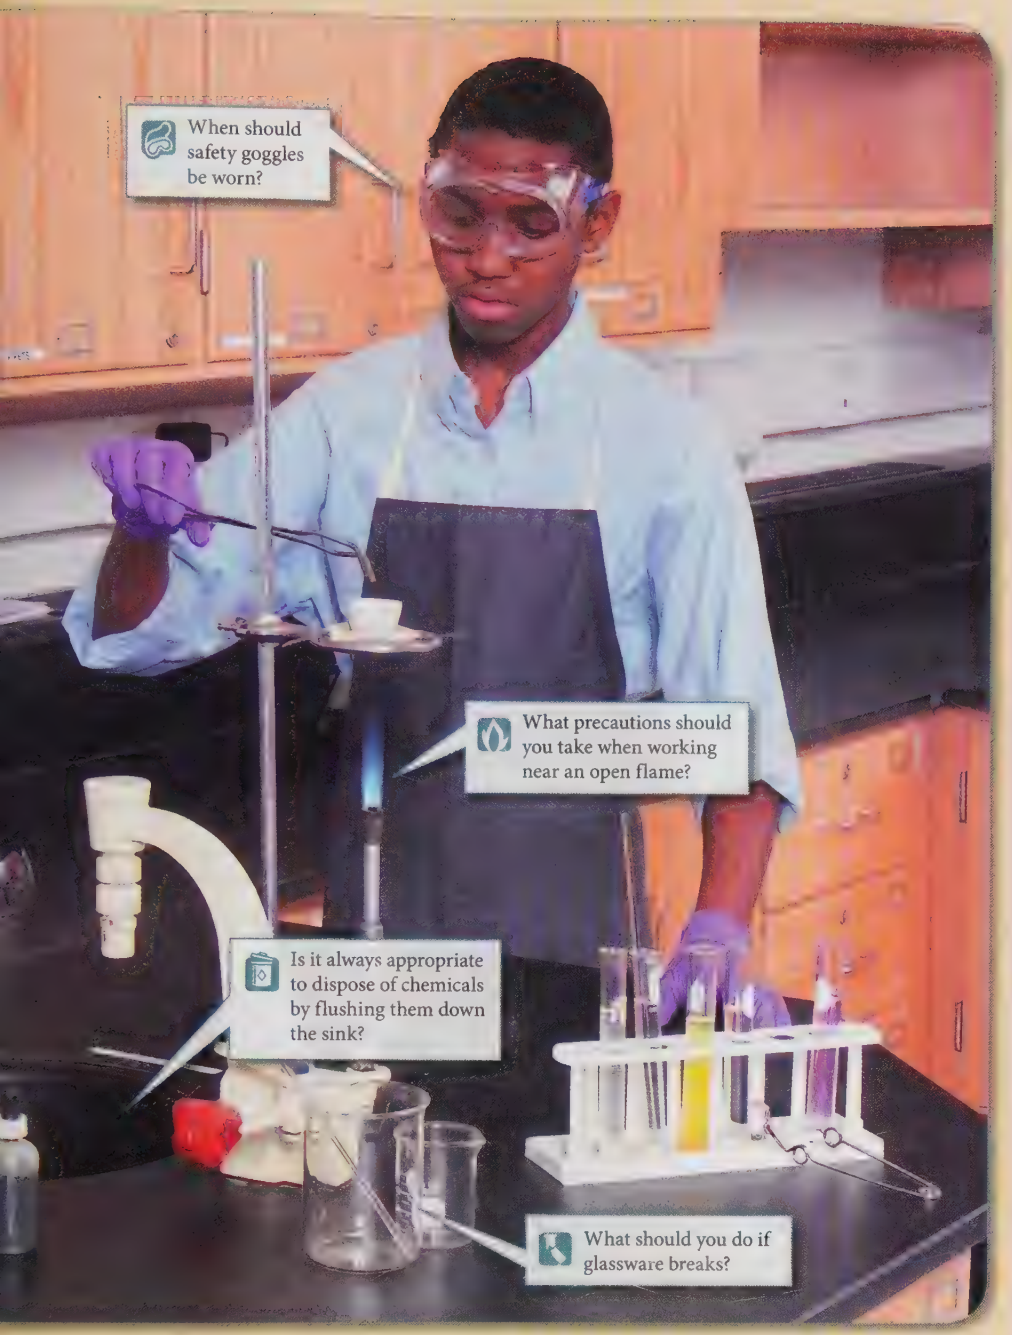
Wash your hands thoroughly with soap and water.

Wear safety goggles at all times when working in the lab.

Tie back long hair and loose clothing. Never reach across a lit burner. Keep flammable materials away from the flame.

It isn't always appropriate to dispose of chemicals by flushing them down the drain. Follow your teacher's instructions for disposal.

Tell your teacher and nearby classmates. Dispose of the glass as instructed by your teacher.



Focus on ELL

4 LANGUAGE PRODUCTION Have students work in groups of four to complete the lab. Make sure each group has ELLs of varied language proficiencies so that more proficient students can help less proficient ones. Have students work according to their proficiency level.

BEGINNING: LOW/HIGH Provide true or false pictures that represent each question on the safety test. For instance, create a picture of a student pouring a chemical into the sink. Students can circle a "thumbs up" or "thumbs down" to indicate if this is a good or bad idea.

INTERMEDIATE: LOW/HIGH Show students how to use the appendix in the textbook.

ADVANCED: LOW/HIGH Have students help students with lower proficiencies with the written answers and predictions.

Background

The small-scale chemistry experiments in this book are designed to help you teach students important chemical principles, not just process. For most experiments, the procedure is short and simple. In many cases, students are asked to construct a grid, place a small-scale reaction surface over the grid, do the experiment, and record their results in a similar grid. Sometimes the students are told to mark the grid with black X's. These X's provide black-and-white backgrounds against which students can observe reaction mixtures.

The YOU'RE THE CHEMIST activities ask students to apply what they learned in the initial experiment. Some of these activities could be used for performance-based assessment.

FOR ENRICHMENT Have students look at the safety rules in Appendix C. Have each student choose five of the rules in Appendix C and make a list of what things could happen if each rule is not followed. Organize students into groups of three and have them share their answers with each other.

Professional Development Note

Laboratory Hazard Symbols

The four-color diamond pictured on page R50 of the text is a familiar sight in every laboratory stockroom and chemical cabinet. The hazard diamond was originally developed by the National Fire Protection Association (NFPA) in response to federal requirements that information about hazardous materials must be visibly posted and easily accessible to all workers. The diamond is divided into four smaller diamonds: blue, red, yellow, and white. The colors symbolize four areas of safety concern. The blue diamond provides information on potential dangers to human health. The red diamond provides information on the flammability of the material. Yellow provides information on the reactivity of the substance. Each of these three diamonds is occupied by a number ranging from 0 to 4, with 0 representing the lowest level of danger and 4 the highest. The white diamond is reserved for special hazards. Instead of numbers, the NFPA system uses two symbols in this diamond—W and OX—to indicate hazards of particular interest to firefighters. The W, often seen with a horizontal line through it, provides information about reactivity with water, and OX indicates that the material is an oxidizer. The official NFPA hazard diamond uses only the W and OX symbols in the white diamond; other versions may have an expanded list that indicates whether a substance is an acid (ACID), a base (ALK), corrosive (COR), or radioactive (universal radioactive warning symbol).

LESSON 1.4

Key Objectives

- **1.4.1 IDENTIFY** the general approach to solving a problem.
- **1.4.2 DESCRIBE** the steps for solving numeric problems.
- **1.4.3 DESCRIBE** the steps for solving nonnumeric problems.

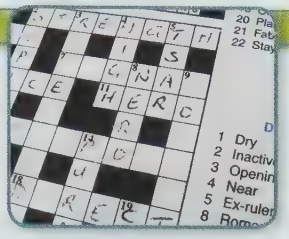
Engage



CHEMISTRY & YOU Have students study the photograph and read the text that opens the lesson. **Ask** Describe your approach to solving a crossword puzzle. *(Sample answer: I try to answer the first five clues across and the first five clues down. I continue like this until I get enough of the puzzle filled in; then I begin to randomly answer the clues.)* **Ask** What is the most effective way you have learned to solve a problem? *(Approaches vary depending on the given problem; effective approaches are generally organized and well planned.)*

Activate Prior Knowledge

Ask students to share the steps of the problem-solving plan they have learned in mathematics courses. Explain that scientists use a similar plan to approach the process of solving chemistry problems.

IN ACADEMIC STANDARDS for SCIENCE

1.4 Problem Solving in Chemistry

CHEMISTRY & YOU

Q: *How does having a plan make solving problems easier?* Have you ever tried to solve a crossword puzzle? If so, you may have found it helpful to develop a strategy before you begin. For example, you may try to fill in all the "down" clues before attempting the "across" clues. Or, you may first try to complete the fill-in-the-blank clues before moving on to the more difficult clues. In chemistry, it is helpful to develop a strategy to solve both numeric and nonnumeric problems.

Key Questions

- ***What is a general approach to solving a problem?***
- ***What are the steps for solving numeric problems?***
- ***What are the steps for solving nonnumeric problems?***

Skills Used in Solving Problems

What is a general approach to solving a problem?

Problem solving is a skill you use all the time. You are in a supermarket. Do you buy a name brand or the store brand of peanut butter? Do you buy the 1-liter bottle or the 2-liter bottle of a carbonated beverage? Do you choose the express line if there are five customers ahead of you or the non-express line with a single shopper who has a lot of items?

When you solve a problem, you may have a data table, a graph, or another type of visual to refer to. The shopper in Figure 1.18 is reading the label on a container while trying to decide whether to buy the item. She may need to avoid certain ingredients because of a food allergy. She may also want to know the number of Calories per serving.

The skills you use to solve a word problem in chemistry are not that different from those you use while shopping, cooking, or planning a party. **Effective problem solving always involves developing a plan and then implementing that plan.**

Figure 1.18 Problem Solving
A shopper must make many decisions. Some of those decisions are based on data, such as the information on a food label.

Focus on ELL

1 CONTENT AND LANGUAGE Present the objectives of the lesson by paraphrasing or using visual aids. Write the words *numeric* and *nonnumeric* on the board. **Ask** What word are you familiar with that sounds similar to *numeric*? *(number)* Explain that *numeric* is an adjective meaning "indicating a number." Tell students that the objectives tell them that they will be learning to solve problems with and without numbers.

2 FRONTLOAD THE LESSON Preview Figures 1.19 and 1.21 and Sample Problems 1.1 and 1.2. Show students how each sample problem is broken down into the steps presented in the corresponding figure. Point out that each sample problem contains hints to help students during the solution process.

3 COMPREHENSIBLE INPUT For Sample Problem 1.1, model writing down the knowns and unknowns while reading through the problem. When explaining Sample Problem 1.2, demonstrate how to use a table to organize the known information and to assist in eliminating some possibilities.

Solving Numeric Problems

What are the steps for solving numeric problems?

Most word problems in chemistry require math because measurement is such an important part of chemistry. The techniques used in this book to solve numeric problems are conveniently organized into a three-step, problem-solving approach. This approach has been shown to be very helpful and effective. We recommend that you follow this approach when working on numeric problems in this textbook. **The steps for solving a numeric word problem are analyze, calculate, and evaluate.** Figure 1.19 summarizes the three-step process, and Sample Problem 1.1 on the next page shows how the steps work in solving a numeric problem.

READING SUPPORT

Build Reading Skills: *Main Ideas* Under the heading Solving Numeric Problems, there are three main ideas presented as subheads. ***What are two details that support each main idea?***

1 Analyze To solve a word problem, you must first determine where you are starting from (identify what is known) and where you are going (identify what is unknown). What is known may be a measurement or an equation that shows a relationship between measurements. If you expect the answer (the unknown) to be a number, you need to determine what unit(s) the answer should have before you do any calculations.

After you identify the known and the unknown, you need to make a plan for using what is known to arrive at the unknown. Planning is at the heart of successful problem solving. As part of planning, you might draw a diagram that helps you visualize a relationship between the known and the unknown. You might need to use a table or graph to identify data or to identify a relationship between a known quantity and the unknown. You may need to select an equation that you can use to calculate the unknown.

2 Calculate If you make an effective plan, doing the calculations is usually the easiest part of the process. For some problems, you will have to convert a measurement from one unit to another. For other problems, you may need to rearrange an equation before you can solve for an unknown. You will be taught these math skills as needed.

3 Evaluate After you calculate an answer, you should evaluate it. Is the answer reasonable? Does it make sense? If not, reread the word problem. Did you copy the data correctly? Did you choose the right equations?

Check that your answer has the correct unit(s) and the correct number of significant figures. You may need to use scientific notation in your answer. You will study significant figures and scientific notation in Chapter 3.

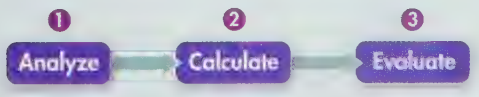


Figure 1.19 Solving Numeric Problems
This flowchart summarizes the steps for solving a numeric problem.
Identify ***In which step do you make a plan for getting from what is known to what is unknown?***

Differentiated Instruction

LPR LESS PROFICIENT READERS Use short, simple words and examples to restate the three steps of solving numeric problems. Have students use a bulleted list to rewrite the steps.

ELL ELL Create a two-column chart relating common key words and mathematical operation symbols. Clarify misinterpretations involving the fraction bar and the division bar. Guide students to understand that those two symbols mean the same thing. State the various words used to read a numerical sentence involving those symbols.

L3 ADVANCED STUDENTS Have students create a list of all the various types of problem-solving plans they have learned throughout previous mathematics and science courses. Ask the students to share and explain each method to the class. Encourage students to use skits, visual aids, and examples to present each method. Students should also note that more than one method can be used to solve a problem.

Foundations for Reading

BUILD VOCABULARY Students may benefit from a reminder that certain key words and phrases in each word problem indicate the unknown quantity and its units. These include *how much*, *determine*, *what is*, *find*, and *how long*. Have students generate a list of key words that indicate an operational symbol, such as *add*, *remove*, and *total*.

READING STRATEGY Some students are convinced they cannot do word problems because the problems are too hard. Tell students to examine one sentence at a time to locate information that will help them solve the problem and list what is already known, such as identities and quantities of substances or experimental conditions.

Explain

Skills Used in Solving Problems

MAKE A CONNECTION Explain that the memorization of facts is a relatively small part of learning chemistry. A person who succeeds in chemistry has become a good problem solver. Encourage students to share problem-solving methods and techniques. Discuss the "supermarket" problems. Stress that for these problems, unlike most problems in a chemistry course, answers can vary and still be correct.

Solving Numeric Problems

START A CONVERSATION Point out that in the laboratory, as well as during students' normal routines, students are often presented with more data than is needed to solve a problem. Explain that they will need to sort essential data from extraneous data. In cases with more than the required data, sorting the data into knowns and unknowns helps students to determine the answer to "What data do I need to solve this problem?"

Answers

READING SUPPORT

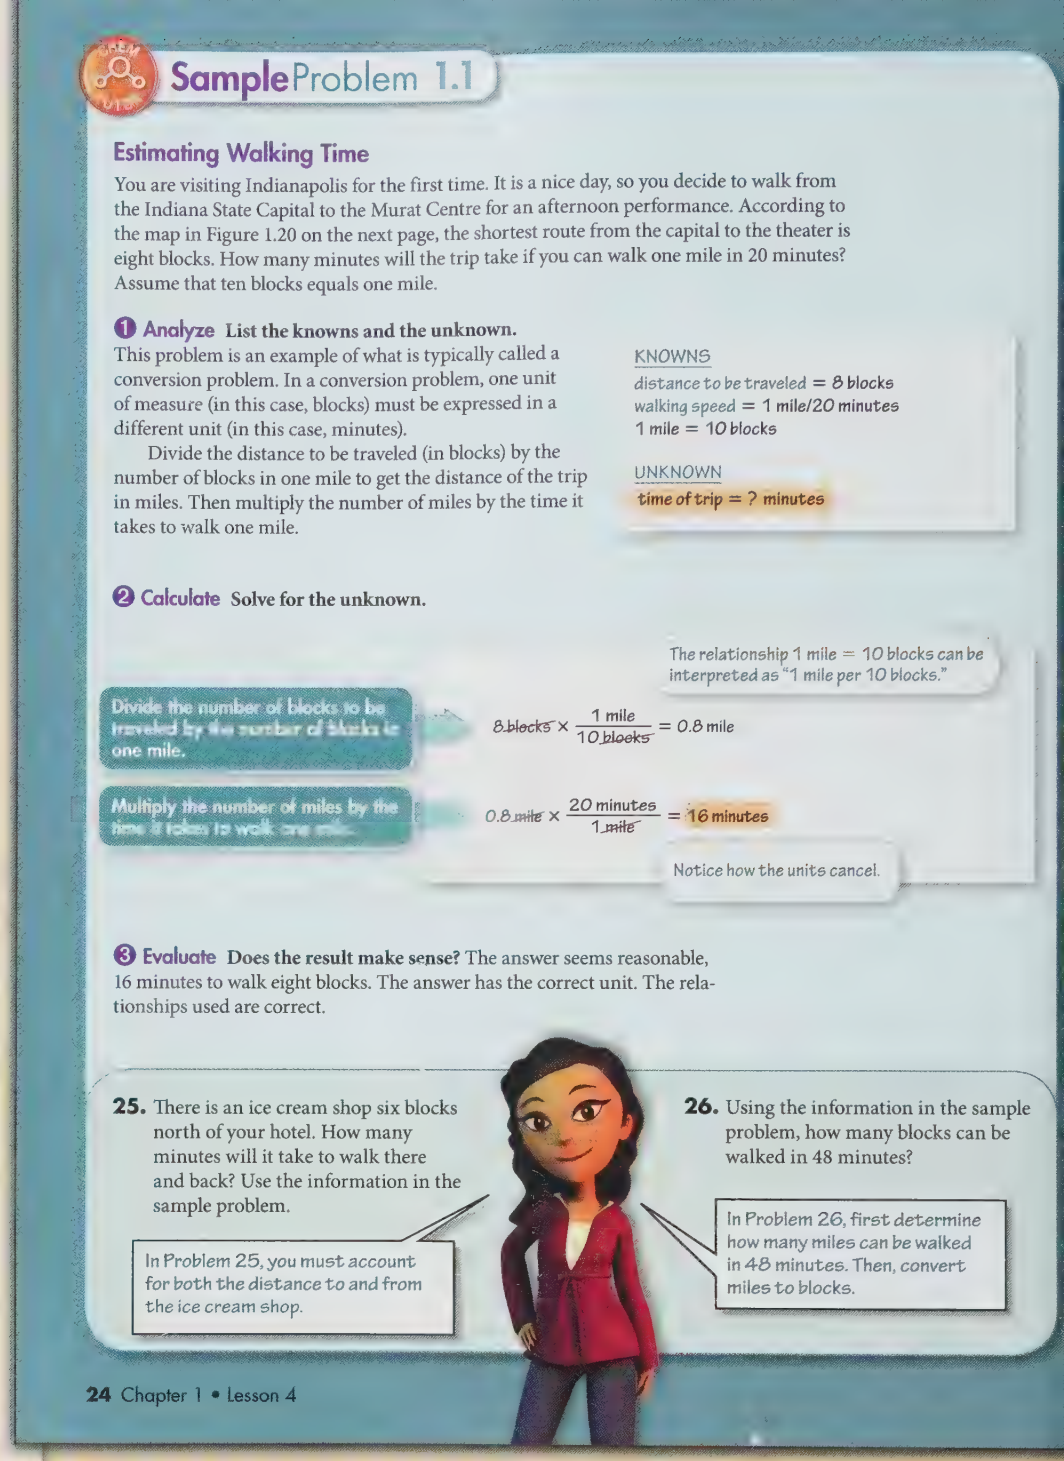
1. Determine where you are starting from and where you are going. Then, make a plan.
2. You may need to convert a measurement from one unit to another. You may need to rearrange an equation before solving for an unknown.
3. If the answer does not make sense, reread the problem. Check that the answer has the correct units.

FIGURE 1.19 Step 1, analyze

Explain

Estimating Walking Time

APPLY CONCEPTS As a class, rewrite the problem to exclude extraneous information, such as *It is a nice day*. Then list the knowns and unknowns on the board as well as the steps needed to calculate the answer. You may wish to use chalk or markers of different colors for the knowns and unknowns to make the process clearer. Stress the importance of evaluating whether the result makes sense. Students should make an initial mental estimate to compare with the final result displayed by a calculator.



Sample Practice Problem

A student maps out a 25-block jogging loop through the downtown streets of Indianapolis. She states that she ran the loop one time in about 15 minutes.

a. How many miles did the student run? *(2.5 miles)*

b. How long did it take the student to run one mile? *(6 minutes)*

c. The next day the student runs for 90 minutes. She states that she ran the loop 4 times. How many miles did she run? What was her running rate in miles per minute and miles per hour? *(10 miles; about 0.11 mile per minute; about 6.7 miles per hour)*

Sample Problem 1.1

Estimating Walking Time

You are visiting Indianapolis for the first time. It is a nice day, so you decide to walk from the Indiana State Capital to the Murat Centre for an afternoon performance. According to the map in Figure 1.20 on the next page, the shortest route from the capital to the theater is eight blocks. How many minutes will the trip take if you can walk one mile in 20 minutes? Assume that ten blocks equals one mile.

1 Analyze **List the knowns and the unknown.**

This problem is an example of what is typically called a conversion problem. In a conversion problem, one unit of measure (in this case, blocks) must be expressed in a different unit (in this case, minutes).

Divide the distance to be traveled (in blocks) by the number of blocks in one mile to get the distance of the trip in miles. Then multiply the number of miles by the time it takes to walk one mile.

KNOWNS

distance to be traveled = 8 blocks
walking speed = 1 mile/20 minutes
1 mile = 10 blocks

UNKNOWN

time of trip = ? minutes

2 Calculate **Solve for the unknown.**

The relationship 1 mile = 10 blocks can be interpreted as "1 mile per 10 blocks."

Divide the number of blocks to be traveled by the number of blocks in one mile.

$$8 \text{ blocks} \times \frac{1 \text{ mile}}{10 \text{ blocks}} = 0.8 \text{ mile}$$

Multiply the number of miles by the time it takes to walk one mile.

$$0.8 \text{ mile} \times \frac{20 \text{ minutes}}{1 \text{ mile}} = 16 \text{ minutes}$$

Notice how the units cancel.

3 Evaluate **Does the result make sense?** The answer seems reasonable, 16 minutes to walk eight blocks. The answer has the correct unit. The relationships used are correct.

25. There is an ice cream shop six blocks north of your hotel. How many minutes will it take to walk there and back? Use the information in the sample problem.

In Problem 25, you must account for both the distance to and from the ice cream shop.

26. Using the information in the sample problem, how many blocks can be walked in 48 minutes?

In Problem 26, first determine how many miles can be walked in 48 minutes. Then, convert miles to blocks.

24 Chapter 1 • Lesson 4

Foundations for Math

CONVERSION PROBLEMS Tell students that this is the most common type of numerical problem they will see in an introductory chemistry course.

IN SAMPLE PROBLEM 1.1, show students how the units in the numerator and the denominator of Step 2 cancel. It may be helpful to show 8 blocks as a fraction, with 8 blocks over 1. Make sure students write units at every step of the problems. Students need to understand that if their answers do not indicate units, the answers are not considered correct. (NOTE: Conversion problems will be discussed in detail in Chapter 3. In that chapter, students will learn how to combine the two calculate steps in Sample Problem 1.1 into a single step.)

Figure 1.20 Reading a Map
Refer to this map of Indianapolis, Indiana, while you do Sample Problem 1.1.

Solving Nonnumeric Problems

What are the steps for solving nonnumeric problems?

Not every word problem in chemistry requires calculations. Some problems ask you to apply the concepts you are studying to a new situation. To solve a nonnumeric problem, you still need to identify what is known and what is unknown. Most importantly, you still need to make a plan for getting from the known to the unknown. If your answer is not a number, you do not need to check the units, make an estimate, or check your calculations.

The three-step problem-solving approach is modified for nonnumeric problems. **The steps for solving a nonnumeric problem are analyze and solve.** Problem-solving methods, such as drawing a diagram, creating a flowchart, or building a model, may be useful. Figure 1.21 summarizes the process, and Sample Problem 1.2 on the next page shows how the steps work in an actual problem.

CHEMISTRY & YOU

Q: *Pick a game you like to play or a type of puzzle you enjoy solving. How does having a plan make playing the game or solving the puzzle easier?*

Figure 1.21 Solving Nonnumeric Problems
This flowchart summarizes the steps for solving a nonnumeric problem.
Compare *With a nonnumeric problem, why is the second step called* solve, *rather than* calculate?

UbD Check for Understanding

The Essential Question **How do chemists solve problems?**

Have students write a one-minute statement describing the steps to follow when solving a nonnumeric problem and a numeric problem.

ADJUST INSTRUCTION If students are having difficulty with the processes for solving these two types of problems, refer students back to Figures 1.19 and 1.21.

Explain

Solving Nonnumeric Problems

MAKE A CONNECTION Discuss using classification schemes as tools for organizing information. **Ask** What classification schemes have you encountered in your daily life? *(Sample answer: the ways that books organized in stores or in libraries)*

Explore

Teacher Demo

PURPOSE Students suggest different approaches for solving a problem.

MATERIALS bowl of ice cubes, empty narrow-neck bottle

PROCEDURE Place a bowl of ice cubes and an empty soda bottle in front of the class. Explain that the problem is to transfer the ice to the inside of the bottle. Have students analyze the problem and suggest different approaches.

EXPECTED OUTCOME Students may suggest crushing the ice so that pieces are small enough to fit through the mouth of the bottle; or they may suggest melting the ice, pouring the water into the bottle, and placing the bottle in a freezer.

CHEMISTRY & YOU Answers will vary, but should include specific examples of how having a plan helped.

Answers

25. 24 minutes
26. 24 blocks

FIGURE 1.21 Solving a nonnumeric problem usually does not require any calculations.

Explain

Sample Practice Problem

How would Manny's schedule change if Physical Education was offered only during 7th period? (*History would have to be moved to 4th period.*)

Evaluate

Informal Assessment

To determine student understanding of the three-step problem-solving approach, ask students to suggest ways to evaluate an answer. *(Reread the problem to be sure the answer supplies the unknown; round off the numbers and do a quick estimate.)* Then have students complete the 1.4 Lesson Check.

Reteach

Have students try working in pairs to solve problems. One student thinks aloud while trying to solve a problem. The other keeps a careful record of the process. Then they reverse roles and work on another problem.

SampleProblem 1.2

Scheduling Classes

Manny needs to schedule his classes for next year. The school day is divided into seven periods, and he must take Algebra II, Art, Chemistry, English, History, and Physical Education. Using the information from the course catalog, find a way for Manny to schedule all his classes.

- ✔ Algebra II is offered during either 1st or 2nd period.
- ✔ Art is offered during 2nd period only.
- ✔ Chemistry is offered during either 3rd or 6th period.
- ✔ English is offered during either 6th or 7th period.
- ✔ History is offered during either 4th or 7th period.
- ✔ Physical Education is offered during 4th period only.
- ✔ Lunch is scheduled for 5th period.

❶ Analyze **Identify the relevant concepts.**
Manny must take lunch during 5th period. Art is only available during 2nd period. Physical Education is only available during 4th period.

❷ Solve **Apply the concepts to this problem.**

Place lunch, Art, and Physical Education into Manny's schedule.

Manny's Schedule	
1st period	
2nd period	Art
3rd period	
4th period	P.E.
5th period	Lunch
6th period	
7th period	

Fit the remainder of the classes into Manny's schedule.

Since Art is only available during 2nd period, Manny must take Algebra II during 1st period. Since P.E. is only available during 4th period, he must take History during 7th period.

Manny's Schedule	
1st period	Algebra II
2nd period	Art
3rd period	Chemistry
4th period	P.E.
5th period	Lunch
6th period	English
7th period	History

27. How would Manny's schedule change if Art was available during 1st period, instead of 2nd period?

28. Would Manny's schedule change if Algebra II was available during 1st, 2nd, and 3rd periods? Explain.

1.4 LessonCheck

29. Review What are the two general steps in successful problem solving?

30. List What are the three steps for solving numeric problems?

31. List What are the two steps for solving nonnumeric problems?

32. Compare and Contrast How are the processes for solving numeric and nonnumeric problems similar? In what way are they different?

33. Calculate Read the following conversion problem, and then answer the questions. "There are 3600 seconds in an hour. How many seconds are there in one day?"

- **a.** Identify the known and the unknown.
- **b.** What relationship between the known and unknown do you need to solve the problem?
- **c.** Calculate the answer to the problem.
- **d.** Evaluate your answer and explain why your answer makes sense.

Lesson Check Answers

29. Develop a plan and implement the plan.

30. The three steps are analyze, calculate, and evaluate.

31. analyze and solve

32. In both cases, the solver analyzes the problem, makes a plan, and carries out the plan. Problems with numeric answers require that the answers be evaluated to see if they are reasonable.

33. **a.** known: 3600 s = 1 h; unknown: ? s = 1 day

b. 24 h = 1 day

c. 3600 s/h × 24 h/day = 86,400 s/day

d. 86,400 seconds in one day seems reasonable in relationship to 3600 seconds in one hour. The answer has the correct units, and the relationship used is correct.

1 Study Guide

BIG IDEA
CHEMISTRY AS THE CENTRAL SCIENCE

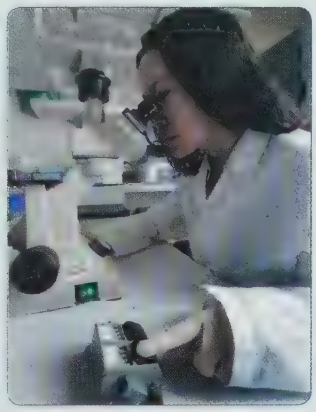
It is important to study chemistry because chemistry is fundamental to the understanding of the other sciences. Chemistry is relevant to many professions. A knowledge of chemistry can help you become an informed citizen. Chemists use the scientific method to solve problems and develop theories about the natural world.

1.1 The Scope of Chemistry

- Chemistry affects all aspects of life and most natural events because all living and nonliving things are made of matter.
- Five traditional areas of study are organic chemistry, inorganic chemistry, biochemistry, analytical chemistry, and physical chemistry.
- Some of chemistry's big ideas are as follows: chemistry as the central science, electrons and the structure of atoms, bonding and interactions, reactions, kinetic theory, the mole and quantifying matter, matter and energy, and carbon chemistry.

- matter (2)
- chemistry (2)
- organic chemistry (3)
- inorganic chemistry (3)
- biochemistry (3)
- analytical chemistry (3)
- physical chemistry (3)
- pure chemistry (3)
- applied chemistry (3)

1.2 Chemistry and You



- Chemistry can be useful in explaining the natural world, preparing people for career opportunities, and producing informed citizens.
- Modern research in chemistry can lead to technologies that aim to benefit the environment, conserve and produce energy, improve human life, and expand our knowledge of the universe.

- technology (8)

1.3 Thinking Like a Scientist

- Lavoisier helped to transform chemistry from a science of observation to the science of measurement that it is today.
- Steps in the scientific method include making observations, proposing and testing hypotheses, and developing theories.
- When scientists collaborate and communicate with one another, they increase the likelihood of a successful outcome.

- scientific method (15)
- observation (15)
- hypothesis (16)
- experiment (16)
- independent variable (16)
- dependent variable (16)
- model (16)
- theory (17)
- scientific law (17)

1.4 Problem Solving in Chemistry

- Effective problem solving always involves developing a plan and then implementing that plan.
- The steps for solving a numeric word problem are analyze, calculate, and evaluate.
- The steps for solving a nonnumeric problem are analyze and solve

Study Guide

Review and Assessment Resources

PROBLEM SETS Have students practice more problems by using the Chapter 1 Online Problem Set.

MATH SKILLS Have struggling students practice manipulating algebraic equations by using the MathXL learning module.

Study Tip

STUDY WITH A FRIEND Encourage students to find a study partner. Tell them to review each section and quiz each other on the key concepts. Suggest that they separately create a summary for each section and then compare notes.

Answers

27. Algebra II would have to move to the second period.

28. The schedule would not need to change unless the schedule for some other class changed.

Focus on ELL

5 ASSESS UNDERSTANDING Assign ELL students one of the Performance Tasks as a group for an alternative assessment. Provide guidelines for the assignment and a grading rubric.

BEGINNING

LOW Create the visual representation for the assignment.

HIGH Find specific text information needed for the assignment.

INTERMEDIATE: LOW/HIGH Provide the written explanation for the visuals.

ADVANCED: LOW/HIGH Present the assignment to the class.

UbD Performance Tasks

IN THE FIELDS Ask students to identify one important discovery and some problems researchers faced during the process of discovery. Tell students to create an oral presentation with visual aids to be presented to the class.

DEBATE Have partners use a newspaper or other media to find a scientific topic that is commonly debated. One student should take the pro side and the other, the con. Each pair of students should research facts and scientists' opinions for support, create guidelines for the debate (such as time limits), and debate the topic in front of the class.

ASSESSMENT

Evaluate

Answers

LESSON 1.1

34. Although air is "invisible," it has mass and occupies space.
35. Chemistry is concerned with the changes that matter undergoes.
36. Organic chemistry is the study of chemicals that contain carbon; inorganic chemistry is the study of chemicals that do not contain carbon.
37. applied research because the research is directed toward a practical goal or application

LESSON 1.2

38. A firefighter needs to know which chemicals to use to fight different types of fires; knowledge of chemistry will help a reporter gather information during an interview with a chemist.
39. Possible products include cups and utensils; containers and packaging for food; and bags.
40. *Sample answer:* Chemists develop medicines to treat conditions such as high blood pressure; materials to replace damaged body parts, and technology such as ways to alter genes.
41. to understand the structure of matter found in cells and chemical changes that occur in cells
42. by analyzing the light they transmit to Earth

LESSON 1.3

43. They based their conclusions on experimental evidence.
44. the scientific method
45. to test a hypothesis
46. c
47. The independent variable is changed during an experiment; the dependent variable is observed during an experiment.
48. Repeat the experiment. If you get the same result, you must propose a new hypothesis.
49. A scientific law summarizes the results of many experiments; a theory explains them.
50. to share knowledge across disciplines and resources between industry and academia

LESSON 1.4

51. b, c, and d
52. developing a plan and implementing that plan
53. Step 1, analyze
54. 54 games (one third of 162)
55. 4320 times an hour, 103,680 times a day
56. 12 days

UNDERSTAND CONCEPTS

57. Answers may vary, but possible answers are 1c, 2d, 3e, 4b, and 5a.

1 Assessment

* Solutions appear in Appendix E

Lesson by Lesson

1.1 The Scope of Chemistry

34. Explain why air is classified as matter.

***35.** The Japanese characters for chemistry literally mean "change study." Why are these appropriate characters to represent chemistry?

化学

36. Describe the main difference between inorganic chemistry and organic chemistry.

***37.** Is a scientist who is studying cancer with the goal of finding an effective treatment doing pure research or applied research?

1.2 Chemistry and You

***38.** Why would a firefighter or a reporter need to understand chemistry?

39. What are some products that could be made from the bioplastic polylactic acid (PLA)?

40. How do chemists help doctors treat patients?

41. What is the overall goal of biochemists who work in the field of medicine?

***42.** How can scientists study the composition of distant stars?

1.3 Thinking Like a Scientist

43. What did the scientists who founded the Royal Society of London have in common with Lavoisier?

***44.** What is the most powerful tool that any scientist can have?

45. What is the purpose of an experiment?

***46.** Which of the following is not a part of the scientific method?

a. hypothesis **c.** guess
b. experiment **d.** theory

47. How do an independent variable and a dependent variable differ?

***48.** You perform an experiment and get unexpected results. According to the scientific method, what should you do next?

***49.** Explain how the results of many experiments can lead to both a theory and a scientific law.

50. List two general reasons why scientists are likely to collaborate.

1.4 Problem Solving in Chemistry

***51.** Identify the statements that correctly describe good problem solvers.

a. read a problem only once
b. check their work
c. look up missing facts
d. look for relationships among the data

52. What do effective problem-solving strategies have in common?

53. In which step of the three-step problem-solving approach for numeric problems is a problem-solving strategy developed?

***54.** On average, a baseball team wins two out of every three games it plays. How many games will this team lose in a 162-game season?

55. If your heart beats at an average rate of 72 times per minute, how many times will your heart beat in an hour? In a day?

***56.** How many days would it take you to count a million pennies if you could count one penny each second?

Understand Concepts

***57.** Match each area of chemistry with a numbered statement.

a. physical chemistry **d.** inorganic chemistry
b. organic chemistry **e.** biochemistry
c. analytical chemistry

(1) measure the level of lead in blood
(2) study non-carbon-based chemicals in rocks
(3) investigate changes that occur as food is digested in the stomach
(4) study carbon-based chemicals in coal
(5) explain the energy transfer that occurs when ice melts

Use this photograph of the runners to answer Questions 58 and 59.

*58. Explain how chemistry has affected the ability of these athletes to compete.

59. What type of chemist might study how an athlete uses energy during a competition? Give a reason for your answer.

60. Explain why chemistry might be useful in a career you are thinking of pursuing.

*61. A doctor examines a patient's sore throat and suggests that the patient has strep throat. She takes a sample to test for the bacteria that cause strep throat. What parts of the scientific method is the doctor applying?

*62. You perform an experiment and find that the results do not agree with an accepted theory. Should you conclude that you made an error in your procedure? Explain.

63. A student is planning a science fair project called "Does Temperature Affect How High a Basketball Can Bounce?"
   a. Based on the project title, identify the independent variable and the dependent variable.
   b. Name at least two factors that would need to be kept constant during the experiment.

64. Describe a situation in which you used at least two steps in the scientific method to solve a problem.

*65. Pure water freezes at 0°C. A student wanted to test the effect of adding table salt to the water. The table shows the data that was collected.

Effect of Salt on Freezing Point of Water

Salt Added	Freezing Point
5 g	−4.8°C
10 g	−9.7°C
15 g	−15.1°C
20 g	15.0°C

   a. What was the independent variable?
   b. What was the dependent variable?
   c. Why must the volume of water be the same for each test?
   d. Based on the data, the student hypothesized, "As more salt is added to water, the temperature at which water freezes decreases." Is this hypothesis supported by the data? Explain.

*66. In the time a person on a bicycle travels 4 miles, a person in a car travels 30 miles. Assuming a constant speed, how far will the car travel while the bicycle travels 40 miles?

Think Critically

67. **Compare and Contrast** How is the study of chemistry similar to the study of a language? How is it different?

68. **Infer** Comment on the idea that science accepts what works and rejects what does not work.

69. **Apply Concepts** You are asked to design an experiment to answer the question: "Which paper towel is the best?"
   a. What is the independent variable in your experiment?
   b. List three possible dependent variables that could be used to define "best."
   c. Pick one of the dependent variables and rewrite the question as a hypothesis.
   d. List at least five factors that must be kept constant when you test the hypothesis.

*70. **Compare** Important discoveries in science are sometimes the result of an accident. Louis Pasteur said, "Chance favors the prepared mind." Explain how both of these statements can be true.

Answers

58. One possible answer is development of the materials to produce an artificial limb.
59. Students are likely to choose biochemist because biochemistry is the study of processes that take place in organisms. However, a student might choose physical chemist because physical chemistry includes the study of energy transfer as matter undergoes a change.
60. Answers will vary but should demonstrate an understanding that chemistry is the study of matter and the changes it undergoes.
61. The doctor's hypothesis is that the sore throat is the result of bacteria that cause strep throat. She tests the hypothesis by testing a sample for the presence of the bacteria.
62. Your experiment may be correct, but your hypothesis may be wrong. You should reexamine your hypothesis and repeat the experiment.

63. a. The independent variable is the temperature of the basketball. The depedent variable is the height of the basketball's bounce.
   b. The method for dropping the basketball before it bounces; the method for measuring the height of the bounce.
64. Answers will vary but should reflect knowledge of the steps in a scientific method including making observations and testing hypotheses.
65. a. amount of salt added
   b. freezing point
   c. Changing the volume of the water would also change the concentration of the salt solution and affect the results.
   d. Yes, to a point. The freezing point appears to be leveling off at about 15°C.
66. 300 miles

THINK CRITICALLY

67. One possible answer is that with both areas of study, students slowly build up a vocabulary and a set of concepts that relate the new terms. Both areas rely on a systematic approach—grammar versus the scientific method. Chemistry deals with matter and words do not qualify as matter. Science is independent of a specific culture; language varies from culture to culture.
68. A possible answer is that scientists accept hypotheses that are supported by experimental results and reject hypotheses that are not supported by experimental results.
69. a. the brand of paper towel
   b. Possible answers include strongest, most absorbent, strongest when wet, largest area per sheet, and easiest to tear from roll.
   c. *Sample answer:* The best towel will absorb the most liquid.
   d. Possible answers include size of paper towel sample, type of liquid, amount of liquid, method for measuring absorbency, method for measuring strength.
70. A person who is educated in the theories and practice of chemistry would be more likely to recognize the significance of an accidental discovery and have the means and motivation to develop that accidental discovery into an important scientific contribution.

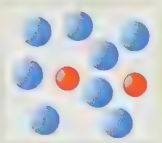
ASSESSMENT

CHEMYSTERY

START A CONVERSATION Have students read over the CHEMystery. As a class, discuss the factors students identified at the beginning of the chapter as important ones to consider before purchasing PLA utensils. **Ask** Did any of the information explained here answer your questions about the utensil material? *(Answers will vary.)* Ask students to tell whether or not they'd purchase this type of utensil, and explain how they made their decisions. Challenge students to find out if any composting facilities for PLA are located in your community.

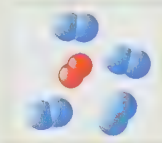
CHEMYSTERY ANSWERS

80. Possible factors in addition to the environmental issues are durability, appearance, cost, and availability.



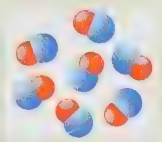
81. BIGIDEA *Sample answer:* A knowledge of chemistry might affect the priority given to environmental concerns.

*71. **Calculate** Four beakers have a total weight of 2.0 lb. Each beaker weighs 0.5 lb. Describe two different methods you could use to calculate the weight of two beakers. Then try both methods and compare the answers.

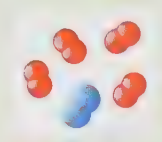


*72. **Apply Concepts** Explain what is wrong with the statement, "Theories are proven by experiments."

*73. **Interpret Diagrams** The air you breathe is composed of about 20% and 80% nitrogen. Use your problem-solving skills to decide which drawing best represents a sample of air. Explain your choice.



a.



c.

b.

d.

Oxygen Nitrogen

Enrichment

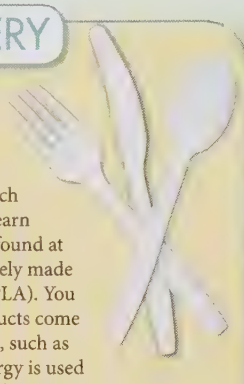
74. **Calculate** A certain ball, when dropped from any height, bounces one-half the original height. If the ball was dropped from a height of 60 inches and allowed to bounce freely, what is the total distance the ball has traveled when it hits the ground for the third time? Assume the ball bounces straight up and down.

*75. **Calculate** Eggs are shipped from a farm to a market by truck. They are packed 12 eggs to a carton and 20 cartons to a box. Four boxes are placed in each crate. Crates are stacked on a truck 5 crates wide, 6 crates deep, and 5 crates high. How many eggs are on the truck?

76. **Analyze Data** An oil tanker containing 4,000,000 barrels of oil is emptied at the rate of 5000 gallons per minute. What information do you need to figure out how long it would take to empty the tanker?

*77. **Calculate** A crate of envelopes sells for $576.00. A package of envelopes contains 250 envelopes. Six packages are packed inside a carton. Twelve cartons are packed in a box. Eight boxes are packed in a crate.

a. What does a package of envelopes cost?
b. What fact given in the problem was not needed to calculate the answer?



Write About Science

78. **Explain** Pick one activity that you can do faster or with less effort because of technology. Write a paragraph in which you describe the activity, identify the technology, and explain how the technology affects the activity.

79. **Relate Cause and Effect** Write a paragraph explaining how you can learn about the research that is done by scientists. Then explain how this information could help you be an informed citizen.

CHEMYSTERY

Is Bio Better?

When you return home from the store, you go online and search for "bioplastics." You learn that the products you found at the store were most likely made from polylactic acid (PLA). You like that the PLA products come from natural resources, such as corn, and that less energy is used in making PLA than other plastics. However, you are concerned that it would be difficult to find a facility that would be able to compost the cups and utensils when you and your friends are finished with them.

*80. **Relate Cause and Effect** What factors will affect your decision as to whether to purchase the picnic products made from PLA? Explain.

81. Connect to the BIGIDEA How would a knowledge of chemistry help you make an informed decision?

Answers

71. Divide the weight of 4 beakers by 2 or multiply the weight of 1 beaker by 2 (2.0 lb/2 or 0.5 lb × 2 = 1 lb).

72. A theory can never be proven. It is a well-tested explanation of a broad set of observations. A theory may need to be changed in the future to explain new observations.

73. c; the 1 to 4 ratio of oxygen to nitrogen corresponds to the composition of air.

ENRICHMENT

74. 150 in.

75. 144,000 eggs

76. the number of gallons in a barrel

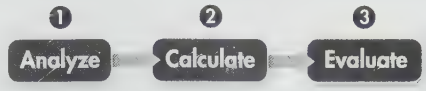
77. **a.** $1.00 per package
b. number of envelopes in a package

WRITE ABOUT SCIENCE

78. Answers will vary but should reflect an understanding of the definition of technology.

79. Students are likely to refer to multiple forms of media. They should also acknowledge the role that citizens play in influencing the direction of scientific research.

Standardized Test Prep for Indiana



Select the choice that best answers each question or completes each statement.

1. The branch of chemistry that studies chemicals containing carbon is _____ chemistry.
   (A) physical
   (B) inorganic
   (C) analytical
   (D) organic
2. An analytical chemist is most likely to
   (A) explain why paint is stirred before it is used.
   (B) explain what keeps paint attached to the steel frame of an automobile.
   (C) identify the type of paint chips found at the scene of a hit-and-run accident.
   (D) investigate the effect of leaded paint on the development of a young child.
3. Chemists who work in the biotechnology field are most likely to work with
   (A) X-ray technicians.
   (B) geologists.
   (C) physicians.
   (D) physicists.

Respond to each statement in Questions 4–6.

4. Someone who wears contact lenses does not have to wear safety goggles in the lab.
5. Eating food that is left over from an experiment is an alternative to discarding the food.
6. For a student who has read the procedure, the teacher's pre-lab instructions are unnecessary.

Use the flowchart to answer Question 7.

7. What should you do before you calculate an answer to a numeric problem, and what should you do after you calculate the answer?

Use this paragraph to answer Questions 8–10.

(A) One day, your car doesn't start. (B) You say, "The battery is dead!" (C) Your friend uses a battery tester and finds that the battery has a full charge. (D) Your friend sees rust on the battery terminals. (E) Your friend says, "Maybe rust is causing a bad connection in the electrical circuit, preventing the car from starting." (F) Your friend cleans the terminals, and the car starts.

8. Which statements are observations?
9. Which statements are hypotheses?
10. Which statements describe experiments?

Tips for Success

True-False Questions When the word *because* is placed between two statements, you must first decide if the statements are both true, both false, or if one statement is true and the other false. If both are true, you must decide if the second statement is a correct explanation for the first.

For each question, there are two statements. Decide whether each statement is true or false. Then decide whether Statement II is a correct explanation for Statement I.

	Statement I		Statement II
11.	A hypothesis may be rejected after an experiment.	BECAUSE	Experiments are used to test hypotheses.
12.	Theories help you make mental models of objects that cannot be seen.	BECAUSE	Theories summarize the results of many observations and experiments.
13.	All Internet sites that provide scientific information are equally reliable.	BECAUSE	All information on these sites is reviewed by qualified scientists.

Materials List

For the Student

Quick Lab p 39
- green marking pen
- filter paper strip
- metric ruler
- clear plastic tape
- pencil
- rubbing alcohol
- clear plastic drinking cup
- clear plastic wrap

Small Scale Lab p 51
- metric ruler
- reaction surface
- 0.1M KI
- 0.2M $CuSO_4$
- 3% H_2O_2
- 1% NaClO
- liquid starch
- cereal
- pipette
- medicine droppers
- spatulas
- iodized and non-iodized salt
- antacid tablets
- colored marking pens
- foods

For the Teacher

Teacher Demo p 35
- plastic syringe (50 mL or larger)
- balance that reads to 0.01 g
- Erlenmeyer flask with tightly fitting 1-hole rubber stopper
- funnel
- water

Class Activity p 36
- foam balls or miniature marshmallows

Teacher Demo p 36
- piece of solid chocolate
- small beaker
- large beaker
- boiling water

Teacher Demo p 40
- iron-fortified breakfast cereal
- 400-mL beaker
- distilled water
- magnetic stirrer with stirring bar

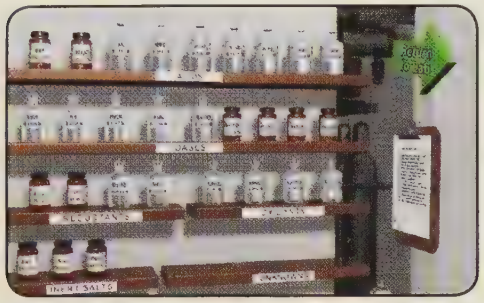
Teacher Demo p 43
- powdered sugar
- 100-mL beaker
- 18M sulfuric acid
- glass stirring rod

Class Activity p 44
- 20 index cards
- masking tape

Teacher Demo p 49
- Bunsen burner
- match
- tongs
- magnesium ribbon
- 4 test tubes
- solutions of 1M $AgNO_3$, 0.1M NaCl, 0.1M K_2CrO_4, and 3M H_2SO_4
- mossy zinc
- marble chip
- spatulas
- cobalt blue glass filters

Additional Digital Resources

Online Student Edition
Online Teacher's Edition
Chemical Reactions



What's Online

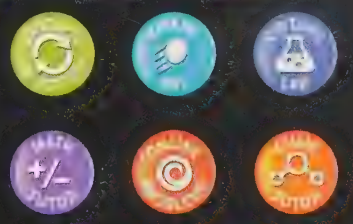
CHEM TUTOR Students access guided, step-by-step tutorials for solving various chemical reaction problems.

PROBLEM SETS Students can practice key problem-solving skills in an online problems set.

MATH HELP Identify the students that struggle with math by assigning an online math skills diagnostic test. These students can then improve and practice math skills by using the MathXL tutorial system.

VIRTUAL LAB Students go on an animated virtual lab tour in which chemical reactions are studied in a simulated laboratory environment.

KINETIC ART watch animations of a selected figures from the chapter followed by questions to check for understanding.



CONCEPTS IN ACTION Students watch an overview of a key chapter concept using real-world contexts and concrete examples and analogies. Each activity includes an interactive animation followed by analysis questions.

IN ACADEMIC STANDARDS for SCIENCE

Nature of Science

- Develop explanations based on reproducible data and observations gathered during laboratory investigations.
- Explain how scientific knowledge can be used to guide decisions on environmental and social issues.

Standard 1: Properties and States of Matter

C.1.1 Based on physical properties, differentiate between pure substances and mixtures

Also covered C.1.2, C.1.3, C.1.4, C.1.5, C.1.6

Focus on ELL

1 CONTENT AND LANGUAGE Write the word *change* on the board and pronounce it for students. Ask volunteers to define this term in their own words. Then explain that the title refers to the fact that matter is capable of undergoing change, and that these changes in matter can be either physical.

BEGINNING: LOW/HIGH Provide students with a simplified definition of change that they can write in their vocabulary notebooks. Allow students to include a native language definition as well.

INTERMEDIATE: LOW/HIGH Have students write several sentences to demonstrate an understanding of the definition.

ADVANCED: LOW/HIGH Have students identify an example of change in the classroom and write a brief paragraph describing the change. Review the paragraphs to assess students' understanding of the definition of *change*.

BIGIDEA

CHEMISTRY AS THE CENTRAL SCIENCE

Essential Questions:

1. *What properties are used to describe matter?*
2. *How can matter change its form?*

CHEMYSTERY

Which One Is Not Like the Others?

In Yellowstone National Park, there are more than 300 geysers. If you are able to witness a geyser erupting, you will see water and steam shooting out of the ground.

In Glacier National Park, the bottoms of glaciers go through melting and freezing cycles. These cycles produce valleys that are scoured into a U-shape and are flanked by steep sides of earth.

In Acadia National Park, the leaves on the deciduous trees change color each fall. The leaves go from green to red, orange, or yellow.

All three of these sights are amazing to see. They all result from changes. Are they physical or chemical changes? One of them is not like the others. But which one is different, and why?

▶ Connect to the BIGIDEA As you read about matter, think about how matter is altered by physical and chemical changes.

INDIANA'S ACADEMIC STANDARDS FOR SCIENCE

Properties and States of Matter C.1.1, C.1.2, C.1.3, C.1.4, C.1.5, C.1.6. See lessons for details.

Introduce the Chapter

CONNECT TO THE REAL WORLD Students observe changes around them on a daily basis. Use the following activities to help students think about differences in changes.

Activity 1 *You'll need a beaker with ice cubes.* Point out that one change students might observe regularly is the melting of ice. **Ask** Does the composition change as the ice melts? *(No; it is frozen water before and liquid water afterward.)*

Activity 2 *You'll need a small ball of cookie dough and a baked cookie made from the dough.* Have students examine the dough and the cookie. Point out that the cookie was baked from the same batch of dough. **Ask** How does the baked cookie differ from the cookie dough? *(Sample answers: The cookie is dry, crisp, and has a crumbly texture; the dough is moist, sticky, and has a smooth texture.)* **Ask** Do you think the composition of the cookie dough changes as it bakes? Explain. *(The composition most likely changes; otherwise the cookie it would have the same physical properties as the dough even after baking.)*

UbD

Understanding by Design

Students are building toward describing matter and change by using Chemistry as the Central Science.

PERFORMANCE GOALS At the end of Chapter 2, students will be able to answer the essential questions by applying their knowledge of matter and change. Students will also be able to describe the law of conservation of mass.

ESSENTIAL QUESTIONS Read the essential questions aloud. Display a piece of paper for the class and have students brainstorm a list of its properties. *(Sample answers: flat, solid, white, easy to bend and tear)* **Ask** What is some ways that paper's form can be changed? *(Sample answers: burning, folding, tearing, dyeing.)*

BIGIDEA Use the photo of the grilled cheese sandwich to help students connect to the concepts they will learn in this chapter. Activate prior knowledge by having them describe their experiences with grilled cheese sandwiches. **Ask** What are some ways that properties of the bread and cheese change as the sandwich is grilled? *(The bread browns and becomes crispy on the outside; the cheese melts and no longer holds its shape.)* **Ask** Do you think these changes are permanent? *(The cheese will re-solidify as the sandwich cools, but will continue to stick to the bread. The outside of the bread cannot change back to its original color or texture.)*

CHEMYSTERY Have students read over the CHEMystery. Connect the CHEMystery to the Big Idea of Chemistry as the Central Science by reminding students that chemistry is the study of the composition of matter and its changes. Have students think about how matter changes when a geyser erupts, the bottom of a glacier melts and refreezes, and leaves change color. Ask them to predict which change is different. As a hint, suggest that they consider whether the composition of matter changes during each event. Also have them predict the difference between a physical change and a chemical change.

LESSON 2.1

Key Objectives

- **2.1.1 EXPLAIN** why all samples of a substance have the same intensive properties.
- **2.1.2 IDENTIFY** three states of matter.
- **2.1.3 CLASSIFY** physical changes.

Additional Resources

Reading and Study Workbook, Lesson 2.1

Available Online or on Digital Media:

- Teaching Resources, Lesson 2.1 Review

PearsonChem.com

Engage

CHEMISTRY & YOU Have students read the opening text. **Ask** Do you know of any other substance that shares the property of transparency with glass? *(Plastic)* **Ask** Why do you think glass was chosen for the aquarium window rather than plastic? Glass has physical properties that make it a better choice for such a large window than plastic, such as transparency and strength.

Activate Prior Knowledge

Ask students to list the three types of matter they encounter every day. *(solids, liquids, and gases)* Have students visualize the structure of each type of matter when viewed under a microscope. Have students compare their mental pictures or actual sketches with the drawings in Figure 2.3.

IN ACADEMIC STANDARDS for SCIENCE

C.1.1 Based on physical properties, differentiate between pure substances and mixtures.

C.1.2 Observe and describe chemical and physical properties of different types of matter and designate them as either extensive or intensive.

C.1.4 Describe physical and chemical changes at the molecular level.

C.1.5 Describe the characteristics of solids, liquids, and gases and state changes at the molecular level.

2.1 Properties of Matter

C.1.1 Pure substance or mixture? C.1.2 Extensive and intensive properties; C.1.4 Physical and chemical changes; C.1.5 States of matter

CHEMISTRY & YOU

Q: *Why are windows made of glass?* When you think of a window, you probably think of something that you can look through. Most windows are made of glass and are transparent, meaning you can see through them. If you found a piece of broken glass on the ground, you would probably recognize it as glass. It is hard, yet easy to shatter, and it is heat resistant. In this lesson, you will learn how properties can be used to classify and identify matter.

Key Questions

- ***Why do all samples of a substance have the same intensive properties?***
- ***What are three states of matter?***
- ***How can physical changes be classified?***

Vocabulary

- mass
- volume
- extensive property
- intensive property
- substance
- physical property
- solid
- liquid
- gas
- vapor
- physical change

Describing Matter

Why do all samples of a substance have the same intensive properties?

Understanding matter begins with observation, and what you observe when you look at a particular sample of matter is its properties. Is a solid shiny or dull? Does a liquid flow quickly or slowly? Is a gas odorless, or does it have a smell? Properties used to describe matter can be classified as extensive or intensive properties.

Extensive Properties Recall that matter is anything that has mass and takes up space. The **mass** of an object is a measure of the amount of matter the object contains. The mass of the basketball in Figure 2.1 is greater than the mass of the golf ball. There is also a difference in the volume of the balls. The **volume** of an object is a measure of the space occupied by the object. The volume of the basketball is greater than the volume of the golf ball. Mass and volume are both examples of extensive properties. An **extensive property** is a property that depends on the amount of matter in a sample.

Intensive Properties Basketballs may appear to be all the same. But, there are properties to consider when selecting a basketball besides mass and volume. The outer covering may be made of leather, rubber, or a synthetic composite. Each of these materials has different properties which make the basketballs suitable for different playing situations. For example, leather balls are suitable for indoor play but not outdoor play. Leather balls absorb water and dirt more than rubber balls. Absorbancy is an example of an intensive property. An **intensive property** is a property that depends on the type of matter in a sample, not the amount of matter.

Figure 2.1 Extensive Properties Golf balls and basketballs have different masses and different volumes.

Focus on ELL

1 CONTENT AND LANGUAGE Assign small groups of mixed proficiencies one content vocabulary term each. Groups should define the term, create a visual example and a non-linguistic representation, and identify any common misinterpretations of the assigned term. Have each group present its word to the class.

2 FRONTLOAD THE LESSON Ask students to state the types of materials used for various features of their residence or classroom, such as windows, walls, and doors. Have students group the materials based on their similarities. Explain that the groupings are an example of classification of matter and that students have used the properties of these materials to classify them. Revisit the activity after the lesson to see if students wish to use their newfound knowledge of properties to change their classifications.

3 COMPREHENSIBLE INPUT Illustrate that substances can be classified in more than one way on the basis of their properties by having students create Venn diagrams to classify the substances listed in Table 2.1. Ask volunteers to share their diagrams with the class.

Identifying a Substance Each object in Figure 2.2 has a different chemical makeup, or composition. The soda can is mainly aluminum. The watering can is mainly copper. Matter that has a uniform and definite composition is called a **substance.** Aluminum and copper are examples of substances, which are also referred to as *pure substances.* **Every sample of a given substance has identical intensive properties because every sample has the same composition.**

Aluminum and copper have some properties in common, but there are differences besides their distinctive colors. Aluminum is highly reflective and is often used in silver paints. Pure copper can scratch the surface of pure aluminum because copper is harder than aluminum. Copper is better than aluminum as a conductor of heat or electric current. Copper and aluminum are both malleable, which means they can be hammered into sheets without breaking. Hardness, color, conductivity, and malleability are examples of physical properties. A **physical property** is a quality or condition of a substance that can be observed or measured without changing the substance's composition.

Table 2.1 lists physical properties for some substances. The states of the substances are given at room temperature. (Although scientists use room temperature to refer to a range of temperatures, in this book it will be used to refer to a specific temperature, 20°C.) Physical properties can help chemists identify substances. For example, a colorless substance that was found to boil at 100°C and melt at 0°C would likely be water. A colorless substance that boiled at 78°C and melted at −117°C would definitely not be water. Based on Table 2.1, it would likely be ethanol.

Figure 2.2 Aluminum and Copper
This soda can is made almost entirely of a thin sheet of aluminum. The watering can is made of copper, which has been hammered to give its textured appearance.
Analyze Data ***Which of the properties listed in Table 2.1 could not be used to distinguish copper from aluminum?***

CHEMISTRY & YOU

Q: *Glass is often used to make windows, while copper is often used in electrical wires. What properties of glass make it a desirable material to use for windows?*

Interpret Data

Physical Properties of Some Substances

Substance	State	Color	Melting point (°C)	Boiling point (°C)
Neon	Gas	Colorless	−249	−246
Oxygen	Gas	Colorless	218	−183
Chlorine	Gas	Greenish-yellow	−101	−34
Ethanol	Liquid	Colorless	−117	78
Mercury	Liquid	Silvery-white	−39	357
Bromine	Liquid	Reddish-brown	−7	59
Water	Liquid	Colorless	0	100
Sulfur	Solid	Yellow	115	445
Aluminum	Solid	Silver	660	2519
Sodium chloride	Solid	White	801	1413
Gold	Solid	Yellow	1064	2856
Copper	Solid	Reddish-yellow	1084	2562

Table 2.1 A substance can be described and identified by its physical properties.
a. Identify Which property can most easily distinguish chlorine from the other gases?
b. Identify A colorless liquid boils at 40°C. Is the substance water? Why or why not?
c. Calculate Which of the liquid substances has the highest melting point? The lowest boiling point?
d. Draw Conclusions Which of the properties would be the most helpful in identifying an unknown substance?

Differentiated Instruction

L3 ADVANCED STUDENTS Ask students to identify two states of matter other than solid, liquid, and gas. Have students prepare a report describing the general characteristics of these states and the conditions under which matter is likely to exist in these states. Students should explain why these states of matter are not common on Earth. *(Plasmas are likely at extremely high temperatures; Bose-Einstein condensates are possible at extremely low temperatures.)*

LPR LESS PROFICIENT READERS Provide steps to follow for reading and extracting information from a reference table. Then have students practice reading Table 2.1 by posing simple questions such as, *What is the boiling point of ethanol?*

L1 SPECIAL NEEDS STUDENTS Help students understand that air is matter by giving each student an air-filled balloon tied with a ribbon. Show or pass around an unfilled balloon. Untie each ribbon and slowly release the air against the student's skin. Explain that a balloon expands because air takes up space.

Foundations for Reading

BUILD VOCABULARY To help students distinguish the word *extensive* from *intensive,* explain that the prefix *in-* means "within." The related word *extend* often refers to an increase in a dimension, such as length, area, or time.

READING STRATEGY Have students strategically read the opening paragraph of the Describing Matter section. Then teach them how to use the self-questioning strategy to frontload their understanding of the content. Guide students to look for the answers to their questions as they read the rest of the section.

Explore

Describing Matter

Teacher Demo

PURPOSE Students will observe that air takes up space and has mass.

MATERIALS plastic syringe (50 mL or larger), balance that reads to 0.01 g, Erlenmeyer flask with tightly fitting 1-hole rubber stopper, funnel, water

PROCEDURE Have students predict whether or not air takes up space and has mass. Determine the mass of the empty syringe. Then determine the mass when the syringe is full of air. Subtract the two masses to find the mass of air in the syringe. Fit the a stopper and funnel into the Erlenmeyer flask. The equipment must be airtight. Quickly pour water through the funnel.

EXPECTED OUTCOME The mass of the air will be about 0.06 g. Some water will run into the flask (air can be compressed) but not very much because air takes up the space in the flask.

Explain

CHEMISTRY & YOU Some of the physical properties that make glass a good material for windows are that glass has a high melting point making it heat resistant, it is transparent, and it is hard.

USE VISUALS Direct students to Table 2.1. **Ask** What is the relationship between the state of a substance at room temperature and its boiling point? *(Substances that are gases at room temperature have boiling points below 20°C; liquids and solids have boiling points above 20°C.)* **Ask** Are the properties listed in the table intensive or extensive? *(intensive)*

Answers

FIGURE 2.2 State; both are solids.

INTERPRET DATA

a. color
b. No; water boils at 100°C.
c. water; bromine
d. melting point or boiling point

Explore

States of Matter

Student Activity

PURPOSE Students will construct models of a solid and a liquid.

MATERIALS foam balls or miniature marshmallows

PROCEDURE Use Figure 2.3 as a guide for the three-dimensional models.

EXPECTED OUTCOME The particles in each model should be closely packed, but the arrangement in the solid should be orderly.

Teacher Demo

PURPOSE Students will observe three states of matter when chocolate is heated.

MATERIALS piece of solid chocolate, small beaker, large beaker, boiling water

SAFETY Use a thermal mitt while handling the boiling water.

PROCEDURE Show students pieces of solid chocolate. Place the pieces in a small beaker surrounded by boiling water in a larger beaker. After a few minutes, **Ask** How many physical states can you discern in the mixture? *(three)*

EXPECTED OUTCOME Three states can be discerned as the chocolate melts: solid, liquid, and vapor. Remind students that their ability to smell the chocolate means that some components of the mixture must have vaporized.

States of Matter

What are three states of matter?

Depending on the circumstances, you use three different words to refer to water—water, ice, and steam. Water, which is a common substance, exists in three different physical states. So can most other substances. **Three states of matter are solid, liquid, and gas.** Certain characteristics that can distinguish these three states of matter are summarized in Figure 2.3.

Solids A **solid** is a form of matter that has a definite shape and volume. The shape of a solid doesn't depend on the shape of its container. The particles in a solid are packed tightly together, often in an orderly arrangement, as shown in Figure 2.3a. As a result, solids are almost incompressible; that is, it is difficult to squeeze a solid into a smaller volume. In addition, solids expand only slightly when heated.

Liquids Look at Figure 2.3b. The particles in a liquid are in close contact with one another, but the arrangement of particles in a liquid is not rigid or orderly. Because the particles in a liquid are free to flow from one location to another, a liquid takes the shape of the container in which it is placed. However, the volume of the liquid doesn't change as its shape changes. The volume of a liquid is fixed or constant. Thus, a **liquid** is a form of matter that has an indefinite shape, flows, yet has a fixed volume. Liquids are almost incompressible, but they tend to expand slightly when heated.

Figure 2.3
The arrangement of particles is different in solids, liquids, and gases.
Relate Cause and Effect ***Use the arrangements of their particles to explain the general shape and volume of solids and gases.***

See states of matter animated online.

Solid In a solid, the particles are packed closely together in a rigid arrangement.

Liquid In a liquid, the particles are close together, but they are free to flow past one another.

Gas In a gas, the particles are relatively far apart and can move freely.

Professional Development Note

Thixotropic Materials

Changes of state are typically associated with changes in temperature. However, the state of matter can also be affected by other variables. Thixotropic materials are solidlike materials that liquefy when subjected to shearing forces. For example, many paints are thixotropic; they thin out when brushed on a surface and thicken when the brush strokes stop, thus keeping the paint from sliding off the wall! A shearing force has an opposite effect on quicksand. Quick movements "thicken" the quicksand and make it much more difficult for a person or animal trapped in it to move. (A shearing force causes two layers to slide in opposite directions along a plane of contact.)

Gases Like a liquid, a gas takes the shape of its container. But unlike a liquid, a gas can expand to fill any volume. A **gas** is a form of matter that takes both the shape and volume of its container. Look back at Figure 2.3c. As shown in the model, the particles in a gas are usually much farther apart than the particles in a liquid. Because of the space between particles, gases are easily compressed into a smaller volume.

The words *vapor* and *gas* are sometimes used interchangeably. But there is a difference. The term *gas* is used for substances, like oxygen, that exist in the gaseous state at room temperature. (*Gaseous* is the adjective form of *gas*.) **Vapor** describes the gaseous state of a substance that is generally a liquid or solid at room temperature, as in *water vapor*.

Physical Changes

How can physical changes be classified?

The melting point of gallium metal is 30°C. Figure 2.4 shows how heat from a person's hand can melt a sample of gallium. The shape of the sample changes during melting as the liquid begins to flow, but the composition of the sample does not change. Melting is a physical change. During a **physical change,** some properties of a material change, but the composition of the material does not change.

Words such as *boil, freeze, melt,* and *condense* are used to describe physical changes. So are words such as *break, split, grind, cut,* and *crush.* However, there is a difference between these two sets of words. Each set describes a different type of physical change. **Physical changes can be classified as reversible or irreversible.** Melting is an example of a reversible physical change. If a sample of liquid gallium is cooled below its melting point, the liquid will become a solid. All physical changes that involve a change from one state to another are reversible. Cutting hair, filing nails, and cracking an egg are examples of irreversible physical changes.

Figure 2.4 Physical Change The silvery substance in the photograph is gallium, which has a melting point of 30°C.
Infer *What can you infer about the temperature of the hand holding the gallium?*

2.1 LessonCheck

1. **Explain** Explain why all samples of a given substance have the same intensive properties.
2. **Identify** Name three states of matter.
3. **Describe** Describe the two categories used to classify physical changes.
4. **Identify** Name two categories used to classify properties of matter.
5. **Interpret Tables** Which property in Table 2.1 can most easily distinguish sodium chloride from the other solids?
6. **Compare and Contrast** In what way are liquids and gases alike? In what way are liquids and solids different?
7. **Explain** Is the freezing of mercury a reversible or irreversible physical change? Explain your answer.
8. **Explain** Explain why samples of platinum and copper can have the same extensive properties but not the same intensive properties.

BIGIDEA
CHEMISTRY AS THE CENTRAL SCIENCE

9. How would understanding the properties of matter be helpful in other fields of study besides chemistry?

Lesson Check Answers

1. Every sample of a given substance has the same chemical composition.
2. solid, liquid, gas
3. Physical changes are either reversible or irreversible. Reversible changes can be "undone," or reversed. Irreversible changes cannot be undone.
4. intensive and extensive properties
5. Color; sodium chloride is the only white solid listed.
6. Liquids and gases both have an indefinite shape. The shape of a solid is definite; the shape of a liquid is indefinite.
7. The freezing of mercury is reversible because solid mercury can be melted.
8. Samples of platinum and copper can have the same mass and volume (extensive properties). They cannot have the same set of intensive properties because they have different chemical compositions.

Explain

Physical Changes

USE VISUALS Direct students to Figure 2.4. Have students study the photograph. Refer them to page 918 (Elements Handbook) for data on the properties of gallium. **Ask** Is the melting of gallium a reversible or irreversible change? *(reversible)* **Ask** What is the physical state of gallium at room temperature? *(solid)*

Evaluate

Informal Assessment

Assess students' understanding of states of matter by having them consider a lit candle. **Ask** How are three states of matter involved when a candle burns? Explain. *(Solid wax has a definite shape and volume; the melted liquid wax is shapeless and runs down the side of the candle; the vapor that forms above the wick has no shape.)* Then have students complete the 2.1 Lesson Check.

Reteach

If possible, bring samples of some of the substances listed in Table 2.1 to class. Describe the physical properties of selected samples and have students practice identifying them by referring to Table 2.1.

9. **BIG**IDEA Answers will vary; possible answers include: choosing materials for automobile parts; combining and cooking foods in a restaurant; handling products for cleaning and maintaining swimming pools.

Answers

FIGURE 2.3 Solids have a definite shape and volume because their particles are in a rigid, orderly arrangement; gases have no definite shape or volume because their particles are relatively far apart and can move freely.

FIGURE 2.4 Because gallium is shown in the liquid state, the temperature of the hand must be greater than 30°C.

LESSON 2.2

Key Objectives

- **2.2.1 EXPLAIN** how mixtures are classified.
- **2.2.2 EXPLAIN** how mixtures can be separated.

Additional Resources

Reading and Study Workbook, Lesson 2.2

Available Online or on Digital Media:

- Teacher Resources, Lesson 2.2 Review

PearsonChem.com

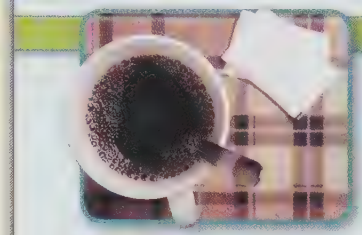
Engage

CHEMISTRY & YOU Have students study the photograph and read the opening text. Explain that the coffee in the cup is also a mixture. **Ask** Can you use a filter to separate the water from the other components of the coffee? Explain. *(no, because the particles are too small)* Point out that not all mixtures can be separated with the same method. Tell students to keep this in mind as they read the lesson.

Activate Prior Knowledge

Review the concepts from Lesson 2.1, directing students' attention back to Table 2.1. Emphasize that the substances in that table are pure substances because they do not contain impurities. Note that in this lesson, students will focus on substances that are not pure.

Foundations for Reading



BUILD VOCABULARY Have students look up the term *homogenize* and explain how this process could be used to turn a heterogeneous mixture into one that is more homogeneous.

IN ACADEMIC STANDARDS for SCIENCE

C.1.1 Based on physical properties, differentiate between pure substances and mixtures

2.2 Mixtures

IN C.1.1 Pure substance or mixture?

CHEMISTRY & YOU

Q: *Why aren't there coffee grounds in a cup of coffee?* Coffee is often brewed by mixing hot water with ground coffee beans. But when people drink coffee, the grounds are usually not in their mug. In this lesson, you will learn how to classify and separate mixtures.

Key Questions

- ***How can mixtures be classified?***
- ***How can mixtures be separated?***

Vocabulary

- mixture
- heterogeneous mixture
- homogeneous mixture
- solution
- phase
- filtration
- distillation

Classifying Mixtures

How can mixtures be classified?

A salad bar, like the one in Figure 2.5, provides a range of items, such as lettuce, tomatoes, cheese, and green peppers. Customers choose which items to use in their salads and how much of each item to use. So each salad mixture has different types and amounts of components. A **mixture** is a physical blend of two or more components.

Most samples of matter are mixtures. Some mixtures are easier to recognize than others. You can easily recognize chicken noodle soup as a mixture of chicken, noodles, and broth. Recognizing air as a mixture of gases is more difficult. But the fact that air can be drier or more humid shows that the amount of one component of air—water vapor—can vary. Chicken noodle soup and air represent two different types of mixtures. **Based on the distribution of their components, mixtures can be classified as heterogeneous mixtures or as homogeneous mixtures.**

Figure 2.5
Salads Are Mixtures
You can choose the amount of each item you select from a salad bar. So your salad is unlikely to have the same composition as other salads containing the same items.

Focus on ELL

1 CONTENT AND LANGUAGE Write the word *mixture* on the board. Have students brainstorm examples of mixtures. Create a list of their ideas. Have students use a dictionary to look up the various uses of the word *mixture*. Once the scientific definition is determined, revisit the list of examples; point to each example and ask the class if it should stay on the list.

2 FRONTLOAD THE LESSON Generate a discussion on the seasonings used in students' favorite foods. Identify seasonings that are blends rather than single herbs or spices. Explain that the blends are examples of mixtures, because they are made by combining two or more spices and/or herbs. Have students predict how this fact explains why different brands of the same spice blend often taste quite different.

3 COMPREHENSIBLE INPUT Perform as many teacher demos and class activities as possible to expose students to a variety of approaches to separating mixtures. Use crumpled and torn paper to demonstrate the difference between reversible and irreversible physical changes.

Quick Lab

Separating Mixtures

Purpose To separate a mixture using paper chromatography

Materials
- green marking pen
- filter paper strip
- metric ruler
- clear plastic tape
- pencil
- rubbing alcohol
- clear plastic drinking cup
- clear plastic wrap

Procedure

1. Use the marking pen to draw a line across a strip of filter paper, as shown in the drawing. The line should be 2 cm from one end of the strip.
2. Tape the unmarked end of the filter paper to the center of a pencil so that the strip hangs down when the pencil is held horizontally, as shown in the diagram below.
3. Working in a well-ventilated room, pour rubbing alcohol into a plastic cup to a depth of 1 cm.
4. Rest the pencil on the rim of the cup so that the ink end of the strip touches the rubbing alcohol but does not extend below its surface. Use plastic wrap to cover the top of the cup.
5. Observe the setup for 15 minutes.

Analyze and Conclude

1. **Identify** How did the appearance of the filter paper change during the procedure?
2. **Analyze Data** What evidence is there that green ink is a mixture?
3. **Apply Concepts** How could you use this procedure to identify an unknown type of green ink?

Heterogeneous Mixtures In chicken noodle soup, the ingredients in the soup are not evenly distributed throughout the mixture. There is likely to be different amounts of chicken and noodles in each spoonful. A mixture in which the composition is not uniform throughout is a **heterogeneous mixture.**

Homogeneous Mixtures The substances in the olive oil in Figure 2.6 are evenly distributed throughout the mixture. So, olive oil doesn't look like a mixture. The same is true for vinegar. Vinegar is a mixture of water and acetic acid, which dissolves in the water. Olive oil and vinegar are homogeneous mixtures. A **homogeneous mixture** is a mixture in which the composition is uniform throughout. Another name for a homogeneous mixture is a **solution.** Many solutions are liquids. But some are gases, like air, and some are solids, like stainless steel, which is a mixture of iron, chromium, and nickel.

The term **phase** is used to describe any part of a sample with uniform composition and properties. By definition, a homogeneous mixture consists of a single phase. A heterogeneous mixture consists of two or more phases. When oil and vinegar are mixed, they form a heterogeneous mixture with two layers, or phases. As shown in Figure 2.6, the oil phase floats on the water, or vinegar, phase.

Figure 2.6 Homogeneous Mixtures
Olive oil and vinegar are homogeneous mixtures. The substances in these mixtures are evenly distributed. When olive oil and vinegar are mixed, they form a heterogeneous mixture with two distinct phases.

Focus on ELL

4 LANGUAGE PRODUCTION Have students work in groups of four to complete the lab. Make sure each group has ELLs of varied language proficiencies so that more proficient students can help less proficient ones. Have students work according to their proficiency level.

BEGINNING: LOW/HIGH Have students draw a picture of their observations.

INTERMEDIATE: LOW/HIGH Allow students to orally explain their observations.

ADVANCED: LOW/HIGH Have students assist students with lower English proficiencies with the calculations and answering the questions.

Explain

Classifying Mixtures

MAKE A CONNECTION Bring orange juice or liquid salad dressing to class and compare the properties of these mixtures to those of pure water or pure NaCl. Explain that mixtures are variable in composition.

Explore

Quick Lab

OBJECTIVE After completing this activity, students will be able to separate the components of a mixture by using paper chromatography.

SKILLS FOCUS Observing, inferring, drawing conclusions

PREP TIME 15 minutes

CLASS TIME 25 minutes

ADVANCE PREPARATION Cut the paper strips in advance to save time. Strips of paper toweling can be used in place of filter paper.

SAFETY Rubbing alcohol is poisonous and flammable. It is also an irritant when inhaled. Keep containers covered and away from heat. If the room is not well ventilated, use a fume hood.

EXPECTED OUTCOME Bands of color will separate on the filter paper.

EXTENSION Students could repeat the lab by using different brands of markers, different colors, or water in place of rubbing alcohol.

ANALYZE AND CONCLUDE

1. Bands of colors appeared as the alcohol moved up the paper.
2. The bands of colors indicate that green ink is a mixture.
3. The color pattern of the unknown ink could be compared with color patterns from known types of green ink.

FOR ENRICHMENT Students can research R_f values of different dyes and how they are calculated (ratio of distance traveled by dye to distance traveled by solvent). They can then quantify this lab by calculating the R_f values of the dyes in the ink.

Explain

Separating Mixtures

USE VISUALS Direct students' attention to Figure 2.8. Review the distillation process, and describe the components of the apparatus. **Ask** What might be an advantage to having a long condenser in a distillation apparatus? *(There would be more surface area on which the vapor can condense.)* **Ask** Is distilled water that contains dissolved gases a pure substance? *(No, distilled water is not pure unless the dissolved gases are removed.)*

CHEMISTRY & YOU Filtration; the brewed coffee passes through the filter paper, but the ground coffee beans do not.

Explore

Teacher Demo

PURPOSE Students will observe the separation of iron filings from iron-fortified breakfast cereal.

MATERIALS iron-fortified breakfast cereal, 400-mL beaker, distilled water, magnetic stirrer with stirring bar

SAFETY Remind students not to eat the cereal.

PROCEDURE Place a stirring bar in a 400-mL beaker. Add about 30 g of cereal to the beaker and add distilled water until the beaker is about half full. Using a magnetic stirrer, mix gently for about 20 minutes. Retrieve the stirring bar and observe the black iron filings attached to it.

EXPECTED OUTCOME Iron filings will cover the stirring bar. They are added to cereal as an iron supplement. Explain that stomach acid changes the iron into a form the body can use.

Figure 2.7 Filtration
A filter is used to separate ground coffee beans from brewed coffee. This process is a type of filtration.

CHEMISTRY & YOU

Q: *Brewing coffee is a mixture of ground coffee beans and water. What process is used to separate ground coffee beans from brewed coffee?*

Separating Mixtures

How can mixtures be separated?

If you have a salad containing an ingredient you don't like, you can use a fork to remove the pieces of the unwanted ingredient. Many mixtures are not as easy to separate. To separate a mixture of olive oil and vinegar, for example, you could decant, or pour off, the oil layer. Or you might cool the mixture until the oil turned solid. The first method takes advantage of the fact that oil floats on water. The second method takes advantage of a difference in the temperatures at which the olive oil and vinegar freeze. **Differences in physical properties can be used to separate mixtures.**

Filtration The coffee filter in Figure 2.7 can separate ground coffee beans from brewed coffee. The liquid brewed coffee passes through the paper filter, but the solid coffee grounds cannot pass through the filter. Filter paper used in a laboratory is similar to coffee filters. Filter paper is often placed in a funnel. Then the mixture is poured into the funnel. Solid particles that cannot pass through the filter remain in the funnel. The rest of the particles in solution pass through the filter paper. The process that separates a solid from the liquid in a heterogeneous mixture is called **filtration.**

Distillation Tap water is a homogeneous mixture of water and substances that are dissolved in the water. One way to separate water from the other components in tap water is through a process called distillation. During a **distillation,** a liquid is boiled to produce a vapor that is then condensed into a liquid. Figure 2.8 shows an apparatus that can be used to perform a small-scale distillation.

As water in the distillation flask is heated, water vapor forms, rises in the flask, and passes into a glass tube in the condenser. The tube is surrounded by cold water, which cools the vapor to a temperature at which it turns back into a liquid. The liquid water is collected in a second flask. The solid substances that were dissolved in the water remain in the distillation flask because their boiling points are much higher than the boiling point of water.

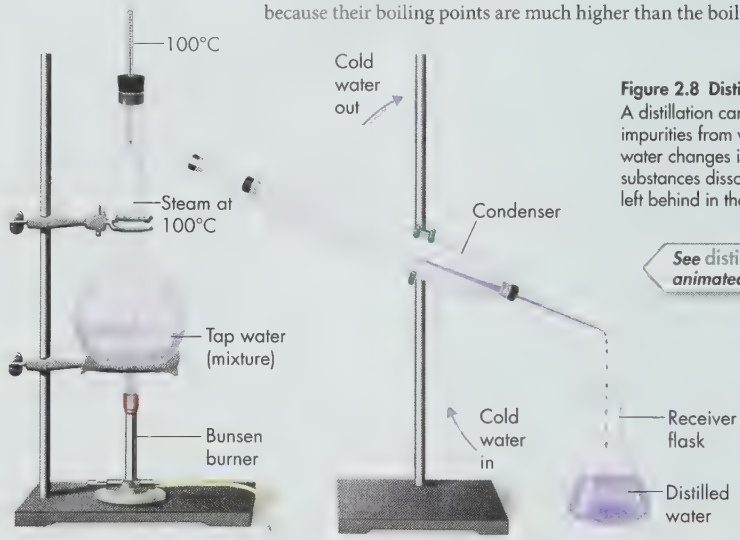


Figure 2.8 Distillation
A distillation can be used to remove impurities from water. As liquid water changes into water vapor, substances dissolved in the water are left behind in the distillation flask.

See distillation *animated online.*

Professional Development Note

Distillation

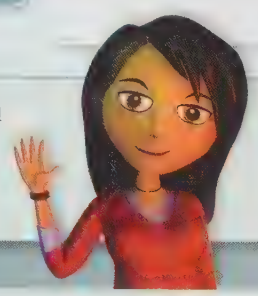
A working distillation apparatus was described in the writings of Maria of Alexandria, an alchemist who lived and worked nearly two thousand years ago. The city of Alexandria, located on the Nile River in North Africa, was a world center of science and culture at that time. Maria of Alexandria is also credited with inventing other chemical apparatus, such as the water bath to this day the water bath is often referred to as the *bain marie* in her honor.

Sample Problem 2.1

Separating a Heterogeneous Mixture

How could a mixture of aluminum nails and iron nails be separated?

1 Analyze **Identify the relevant concepts.** In order to identify how to separate aluminum and iron nails, the properties of both aluminum and iron must be known.



2 Solve **Apply concepts to this situation.**

List the properties of each substance in the mixture.

Aluminum	Iron
• metal	• metal
• gray color	• gray color
• doesn't dissolve in water	• doesn't dissolve in water
• not attracted to magnet	• attracted to magnet

Identify a property that can be used to separate different substances from each other.

The ability to be attracted by a magnet is a property that iron and aluminum do not share. You could use a magnet to remove the iron nails from a mixture of iron and aluminum.

10. What physical properties could be used to separate iron filings from table salt?

11. Air is mainly a mixture of nitrogen and oxygen, with small amounts of other gases such as argon and carbon dioxide. What property could you use to separate the gases in air?

2.2 LessonCheck

12. **Identify** How are mixtures classified?

13. **List** What type of properties can be used to separate mixtures?

14. **Explain** Explain the term *phase* as it relates to homogeneous and heterogeneous mixtures.

15. **Classify** Classify each of the following as a homogeneous or heterogeneous mixture.
- **a.** food coloring
- **b.** ice cubes in liquid water
- **c.** mouthwash
- **d.** mashed, unpeeled potatoes

16. **Compare and Contrast** How are a substance and a solution similar? How are they different?

17. **Apply Concepts** In general, when would you use filtration to separate a mixture? When would you use distillation to separate a mixture?

18. **Explain** Describe a procedure that could be used to separate a mixture of sand and table salt.

BIGIDEA
CHEMISTRY AS THE CENTRAL SCIENCE

19. Give three examples of when you have separated mixtures at home.

Lesson Check Answers

12. as heterogeneous or homogeneous

13. differences in physical properties

14. A phase is any part of a sample with uniform composition. A homogeneous mixture has one phase; a heterogeneous mixture has two or more phases.

15. **a.** homogeneous **b.** heterogeneous **c.** homogeneous **d.** heterogeneous

16. Both have a uniform composition throughout. A substance has a definite composition; a solution has a variable composition.

17. Filtration separates solids from a liquid in a heterogeneous mixture. Distillation can separate a liquid from substances dissolved in the liquid.

18. Add water to dissolve the salt. Filter the mixture to remove the sand. Evaporate the water from the liquid to isolate the solid salt.

19. **BIG**IDEA Answers will vary; examples of mixtures at home include: sorting laundry, draining cooked pasta, putting away bags of groceries.

Sample Practice Problem

Describe how you could separate metal paper clips and plastic paper clips in a bucket of paper clips. *(A magnet could be used to remove the metal paper clips.)*

Evaluate

Informal Assessment

Have students identify five items that fit each of the following categories:

1. substance
2. homogeneous mixture
3. heterogeneous mixture
4. solution

Have students select three items, one each from categories 2, 3, and 4. For each item selected, students should outline a method for separating the components. Then have students complete the 2.2 Lesson Check.

Reteach

Explain that distillation can be used to separate a mixture of gases. Show students the drawing of the fractional distillation of liquid air, on page R24 of the Elements Handbook. **Ask** What physical property is used to separate the gases? *(boiling point)*

Answers

10. Iron is magnetic; table salt is not. Table salt will dissolve in water; iron will not.

11. By lowering the temperature to below the boiling point of each gas, you could condense each substance and separate the gases.

LESSON 2.3

Key Objectives

- **2.3.1 EXPLAIN** the difference between an element and a compound.
- **2.3.2 DISTINGUISH** between a substance and a mixture.
- **2.3.3 DESCRIBE** what chemists use to represent elements and compounds.
- **2.3.4 EXPLAIN** how a periodic table is useful.

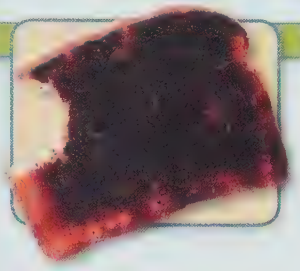
Engage

CHEMISTRY & YOU Have students examine the photo and read the opening text. Ask students who have eaten or smelled burned toast to describe its properties. Explain that the burned taste is due to a chemical reaction between sugar and amino acids, which are chemical compounds in the bread.



Activate Prior Knowledge

Review heterogeneous and homogeneous mixtures. **Ask** What are two methods that can be used to separate mixtures? *(filtration and distillation)* **Ask** Do these methods change the composition of the substances in the mixtures? *(no)* Tell students to keep this in mind as they read the lesson.

IN ACADEMIC STANDARDS for SCIENCE

- Develop explanations based on reproducible data and observations gathered during laboratory investigations.

2.3 Elements and Compounds

CHEMISTRY & YOU

Q: *Why does burned toast taste so bad?* Bread that is toasted to a nice golden brown makes for a tasty addition to breakfast. But most people would agree that bread that is cooked so long that it is burned and black is not tasty.

Key Questions

- *How are elements and compounds different?*
- *How can substances and mixtures be distinguished?*
- *What do chemists use to represent elements and compounds?*
- *Why is a periodic table useful?*

Vocabulary

- element
- compound
- chemical change
- chemical symbol
- periodic table
- period
- group

Distinguishing Elements and Compounds

How are elements and compounds different?

Substances can be classified as elements or compounds. An **element** is the simplest form of matter that has a unique set of properties. Oxygen and hydrogen are two of the more than 100 known elements. A **compound** is a substance that contains two or more elements chemically combined in a fixed proportion. For example, carbon, oxygen, and hydrogen are chemically combined in the compound sucrose. Sometimes sucrose is called table sugar to distinguish it from other sugar compounds. In every sample of sucrose, there are twice as many hydrogen particles as oxygen particles. The proportion of hydrogen particles to oxygen particles in sucrose is fixed. There is a key difference between elements and compounds. **Compounds can be broken down into simpler substances by chemical means, but elements cannot.**

Breaking Down Compounds Physical methods that are used to separate mixtures cannot be used to break a compound into simpler substances. Boil liquid water and you get water vapor, not the oxygen and hydrogen that water contains. Dissolve a sugar cube in water and you still have sucrose, not oxygen, carbon, and hydrogen. This result does not mean that sucrose or water cannot be broken down into simpler substances. But the methods must involve a chemical change.

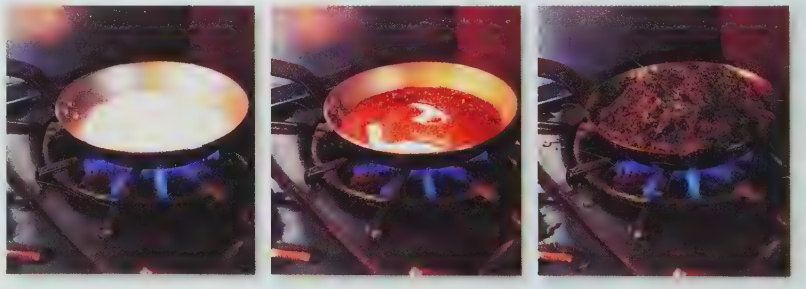


Figure 2.9 Chemical Changes When table sugar is heated, it goes through a series of chemical changes. The final products of these changes are solid carbon and water vapor.

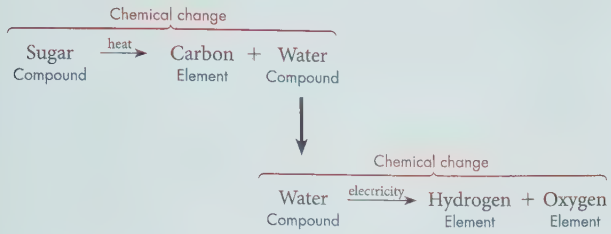
Focus on ELL



1 CONTENT AND LANGUAGE Write the words *element*, *compound*, *change* on the board and pronounce them for the students. Explain that these words have both common and scientific meanings. Provide students with the common definitions and have students write them in their vocabulary notebooks. Remind students to leave room to add the scientific definitions as they discover them in the lesson.

2 FRONTLOAD THE LESSON Write a series of recognizable two-letter abbreviations, such as those used for U.S. states, on the board. Ask for a show of hands of students who can readily identify one or more of the abbreviations. Explain that an abbreviation is a form of symbol. Have students consider how the use of symbols in chemistry might make it easier for scientists to communicate with each other.

3 COMPREHENSIBLE INPUT Guide students to use a think-aloud process as they use the flowchart in Figure 2.11 to classify various types of matter. Suggest possible lines of thought, such as, *Is the matter a pure substance or a mixture of substances?* and *Can the matter by physically separated or chemically separated?*

A **chemical change** is a change that produces matter with a different composition than the original matter. Heating is one of the processes used to break down compounds into simpler substances. The layer of sugar in Figure 2.9 is heated in a skillet until it breaks down into solid carbon and water vapor. Can the substances that are produced also be broken down?

There is no chemical process that will break down carbon into simpler substances because carbon is an element. Heat will not cause water to break down, but electricity will. When an electric current passes through water, oxygen gas and hydrogen gas are produced. The following diagram summarizes the overall process.

Properties of Compounds In general, the properties of compounds are quite different from those of their component elements. Sugar is a sweet-tasting, white solid, but carbon is a black, tasteless solid. Hydrogen is a gas that burns in the presence of oxygen—a colorless gas that supports burning. The product of this chemical change is water, a liquid that can stop materials from burning. Figure 2.10 shows samples of table salt (sodium chloride), sodium, and chlorine. When the elements sodium and chlorine combine chemically to form sodium chloride, there is a change in composition and a change in properties. Sodium is a soft, gray metal. Chlorine is a pale yellow-green poisonous gas. Sodium chloride is a white solid.

CHEMISTRY & YOU

Q: *What happens to the compounds in bread when it is overcooked that causes the changes to the taste of the bread?*

Figure 2.10 Properties of Compounds and Their Elements Compounds and the elements from which they form have different properties. The elements sodium and chlorine have different properties from each other and from the compound sodium chloride.
Observe ***Based on the photographs, describe two physical properties of sodium and two of chlorine.***

Sodium is stored under oil to keep it from reacting with oxygen or water vapor in air. Sodium vapor produces the light in some street lamps.

Chlorine is used to make compounds that kill harmful organisms in swimming pools.

Sodium chloride (commonly known as table salt) is a compound used to season or preserve food.

Differentiated Instruction

LPR LESS PROFICIENT READERS Have students list the key questions in their notebooks, leaving space after each question. As they read the lesson, they should list terms and phrases or create drawings that give the information needed for the answers. Check entries for accuracy.

L3 ADVANCED STUDENTS Other forms of energy besides electricity can be used to bring about the decomposition of water into hydrogen and oxygen. Ask students to consider whether heat could be used for this purpose. Tell them that early chemists considered water to be an element because it would not decompose when heated. Have students research the conditions necessary to decompose water using heat. Ask students to find what hazards, if any, might preclude the routine use of this method.

Foundations for Reading

BUILD VOCABULARY Compare the common meanings of *element, elemental,* and *elementary* in relation to the specific use of *element* in chemistry. In the broadest sense, the terms refer to fundamentals, first principles, or basics.

Explain

Distinguishing Elements and Compounds

USE VISUALS Have students study Figure 2.9. **Ask** What causes the chemical changes? *(the addition of heat)* **Ask** How do the photos and caption convince you that sugar is a compound and not an element? *(The photos and caption show that sugar can be broken down into simpler substances: solid carbon and water vapor. Elements cannot be broken down into simpler substances.)*

CHEMISTRY & YOU When bread overcooks, the compounds in the bread undergo a chemical change and break down into other compounds. The compounds produced have a different taste and appearance.

Explore

Teacher Demo

PURPOSE Students will observe the decomposition of sugar by acid.

MATERIALS 100-mL beaker, powdered sugar, 18*M* sulfuric acid, glass stirring rod

SAFETY Perform the demo in a fume hood or in a well-ventilated area and be sure to wear safety goggles.

CAUTION *This is an extremely exothermic reaction.*

PROCEDURE Place about 25 g of powdered sugar in a 100-mL beaker. Carefully add about 10–15 mL of 18*M* sulfuric acid and stir rapidly with a glass rod.

DISPOSAL Place the cooled beaker and its contents in a large beaker and add water. Neutralize with NaOH and pour the liquid down the drain, flushing with excess water. Throw the solid residue in the trash.

EXPECTED OUTCOME The mixture turns dark, and a column of carbon rises out of the beaker.

Answers

FIGURE 2.10 sodium: gray color, shiny, solid at room temperature; chlorine: yellow-green color, gas at room temperature

Explain

Distinguishing Substances and Mixtures

USE VISUALS Have students examine the flowchart in Figure 2.11. **Ask** Can compounds be separated into their component elements by physical processes? *(No, they must be separated by chemical processes.)* Have students suggest two other examples for each of the four classifications and explain why each example matches the definition of its classification.

Explore

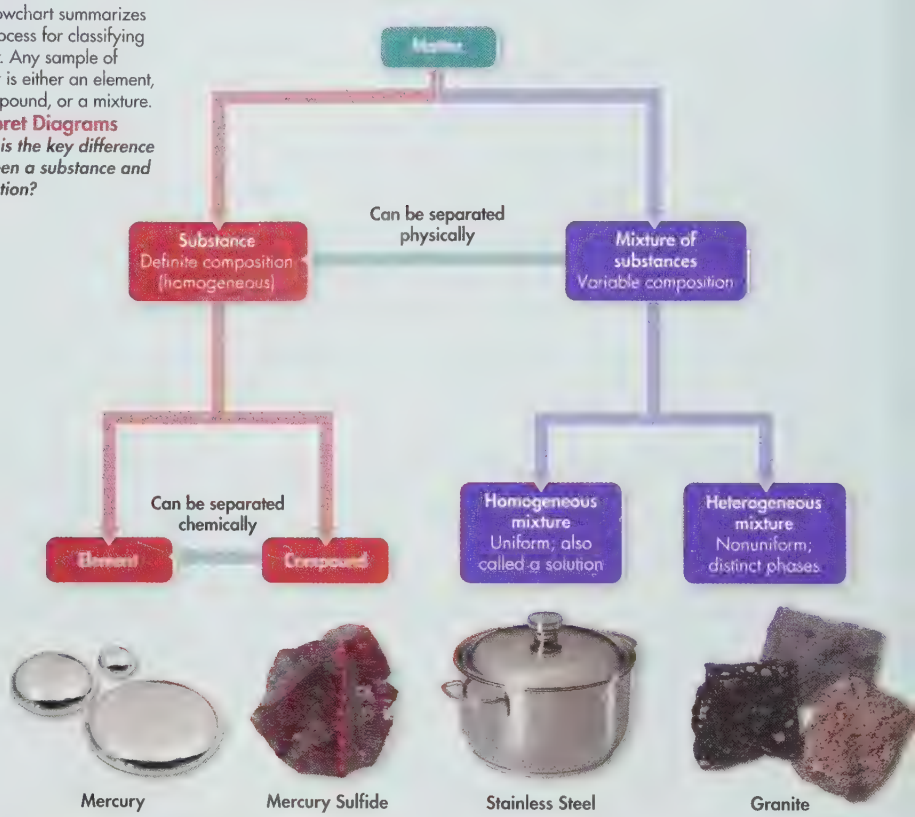
Substances

PURPOSE Students will use an inductive approacth to establish the definition of *substance*.

MATERIALS 20 index cards, masking tape

PROCEDURE Make signs with the number and name of each of these items: 1 oxygen, 2 neon, 3 apple, 4 sand, 5 iron, 6 water, 7 air, 8 paint, 9 sodium chloride, 10 sucrose, 11 carbon dioxide, 12 granite, 13 laundry detergent, 14 citric acid, 15 cereal, 16 salad, 17 salad dressing, 18 copper, 19 ocean water, 20 gold. Use masking tape to create two columns on the board or wall. Place items 1 and 2 in Column A and items 3 and 4 in Column B. Ask students to think about the criteria for each column. Then place item 5 in Column A. Students may have to change their criteria. Place item 6 in Column A. Ask students what they think the criteria are now. Continue placing one item at a time in a column until students understand the criteria. Everything in Column A has a uniform and definite composition.

EXPECTED OUTCOME Column A is for substances: 1, 2, 5, 6, 9, 10, 11, 14, 18, 20. Column B is for mixtures: 3, 4, 7, 8, 12, 13, 15, 16, 17, 19. Make sure students understand the difference between the uniform composition of a substance and the composition of a mixture. The composition of the substance is fixed. The composition of the mixture can vary.



Distinguishing Substances and Mixtures

How can substances and mixtures be distinguished?

Deciding whether a sample of matter is a substance or a mixture based solely on appearance can be difficult. After all, homogeneous mixtures and substances will both appear to contain only one kind of matter. Sometimes you can decide by considering whether there is more than one version of the material in question. For example, you can buy whole milk, low-fat milk, no-fat milk, light cream, or heavy cream. From this information, you can conclude that milk and cream are mixtures. You might infer that these mixtures differ in the amount of fat they contain. Most gas stations offer at least two blends of gasoline. The blends have different octane ratings and different costs per gallon, with premium blends costing more than regular blends. So gasoline must be a mixture.

You can use their general characteristics to distinguish substances from mixtures. **If the composition of a material is fixed, the material is a substance. If the composition of a material may vary, the material is a mixture.** Figure 2.11 summarizes the general characteristics of elements, compounds, and mixtures.

Figure 2.11 Element, Compound, or Mixture? The flowchart summarizes the process for classifying matter. Any sample of matter is either an element, a compound, or a mixture.
Interpret Diagrams ***What is the key difference between a substance and a solution?***

UbD Check for Understanding

How can substances and mixtures be distinguished?

To assess students' understanding of the difference between substances and mixtures, ask students to use a thumbs-up gesture if they are confident in their ability to distinguish between the two classifications of matter. Instruct students to use a thumbs-down gesture to indicate continuing confusion about the difference between the two classifications.

ADJUST INSTRUCTION If students indicate discomfort with their level of understanding, review Figure 2.11 with students. Then provide students with additional practice in using the flowchart to identify a group of samples as either substances or mixtures.

Sample Problem 2.2

Classifying Materials

When a certain blue-green solid is heated, a colorless gas and a black solid form. All three materials are substances. Is it possible to classify these substances as elements or compounds?

1 Analyze **Identify the relevant concepts.** A compound can be broken down into simpler substances by a chemical change, but an element cannot. Heating can cause a chemical change.

2 Solve **Apply concepts to this situation.**

List the known facts and relevant concepts.

- A blue-green solid is heated.

Determine if the substances are elements or compounds.

- A colorless gas and a black solid appear

Before heating, there was one substance. After heating, there were two substances. The blue-green solid must be a compound. Based on the information given, it isn't possible to know if the colorless gas and the black solid are elements or compounds.

20. Liquid A and Liquid B are clear liquids. They are placed in open containers and allowed to evaporate. When evaporation is complete, there is a white solid in container B but no solid in container A. From these results, what can you infer about the two liquids?

21. A clear liquid in an open container is allowed to evaporate. After three days, a solid is left in the container. Was the clear liquid an element, a compound, or a mixture? How do you know?

Symbols and Formulas

What do chemists use to represent elements and compounds?

The common names *water* and *table salt* do not provide information about the chemical composition of these substances. Also, words are not ideal for showing what happens to the composition of matter during a chemical change. **Chemists use chemical symbols to represent elements, and chemical formulas to represent compounds.**

Using symbols to represent different kinds of matter is not a new idea. For thousands of years, alchemists used symbols, such as the ones in Figure 2.12, to represent elements. The symbols used today for elements are based on a system developed by a Swedish chemist, Jöns Jacob Berzelius (1779–1848). He based his symbols on the Latin names of elements. Each element is represented by a one- or two-letter **chemical symbol.** The first letter of a chemical symbol is always capitalized. When a second letter is used, it is lowercase.

Figure 2.12 Element Symbols The symbols used to represent elements have changed over time. Alchemists and the English chemist John Dalton (1766–1844) both used drawings to represent chemical elements. Today, elements are represented by one- or two-letter symbols.

Differentiated Instruction

L1 SPECIAL NEEDS STUDENTS Work with students in creating a large game board out of Figure 2.11. Use large print and symbols for words and colored pathways for the flow options. When asking students to classify matter, have them start with a game piece at the top of the game board and follow along the pathways, pausing at each classification. Use the light from a flashlight or gently clap your hands to signal that students are on the correct path. Tell students that when the light is off or when they no longer hear clapping, they are not on the right path.

ELL ENGLISH LANGUAGE LEARNERS Have students make flashcards to help them learn the names and symbols of at least 30 elements. If an element has a different common name in a student's native country, have the student include that information on the flashcard.

Explain

Sample Practice Problem

Have students classify each of the following types of matter as an element, a compound, or a mixture and provide reasons for their answers.

a. Epsom salt (magnesium sulfate) *(Compound; it is composed of at least two elements.)*

b. hydrogen peroxide (H_2O_2) *(Compound; it is composed of two elements.)*

c. mercury (Hg) *(Element; its symbol shows that it is composed of only one kind of matter.)*

d. sweetened iced tea *(Mixture; it has a composition that can vary.)*

Symbols and Formulas

APPLY CONCEPTS Point out that the use of chemical symbols is an example of the "international language of chemistry." Discuss why people all over the world use the same set of chemical symbols. Show how symbols are used in chemical formulas. Emphasize that a compound is always made up of the same elements in the same proportions. Encourage students to begin a symbol reference sheet and place it in their notebooks where it can be accessed easily—for instance, inside the front cover.

Answers

FIGURE 2.11 The composition of a substance is fixed; the composition of a solution may vary.

20. Liquid A is probably a substance. Liquid B is a mixture.

21. The liquid was not an element because a solid was left when the liquid evaporated. A physical process, such as evaporation, cannot be used to break down a compound. Therefore, the liquid was a mixture.

Explain

The Periodic Table—A Preview

USE VISUALS Direct students to examine Table 2.2 and Figure 2.13. Have students locate the elements given in Table 2.2 on the periodic table. **Ask** Why do some elements have symbols that are similar to the spelling of their names (for example, helium, He) and others have symbols that seem to have nothing to do with names (for example, sodium, Na)? *(Only some element names are derived from their English names, and others are derived from their Latin names, Greek names, the names of scientists who discovered the elements, or other names.)* **Ask** Are the elements in alphabetical order on the periodic table? *(no)* **Ask** What do the numbers above the element symbols represent? *(atomic numbers)* Encourage students to familiarize themselves with the names and the symbols of the elements. Explain that in Chapter 4 students will explore the periodic table in depth.

Extend

Connect to HISTORY

Have students explore the history of science by asking them to work collaboratively in creating a timeline for the discovery of the chemical elements. Encourage students to use the timeline to detect shifts in naming conventions. Ask students to predict whether the timeline of element discovery has anything to do with the location of the elements on the periodic table.

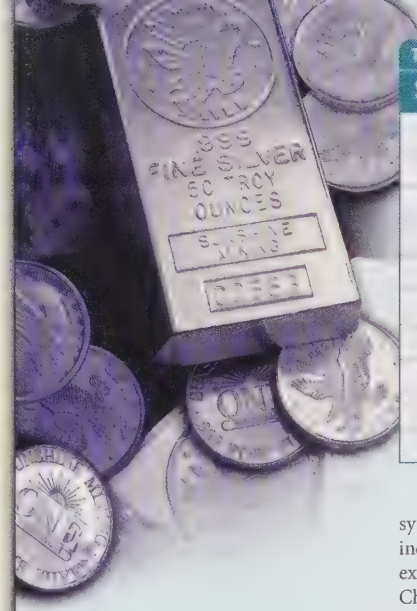


Table 2.2

Symbols and Latin Names for Some Elements

Name	Symbol	Latin name
Sodium	Na	*natrium*
Potassium	K	*kalium*
Antimony	Sb	*stibium*
Copper	Cu	*cuprum*
Gold	Au	*aurum*
Silver	Ag	*argentum*
Iron	Fe	*ferrum*
Lead	Pb	*plumbum*
Tin	Sn	*stannum*

If the English name and the Latin name of an element are similar, the symbol will appear to have been derived from the English name. Examples include Ca for calcium, N for nitrogen, and S for sulfur. Table 2.2 shows examples of elements for which the symbols do not match the English names. Chemical symbols provide a shorthand way to write the chemical formulas of compounds. The symbols for hydrogen, oxygen, and carbon are H, O, and C. The formula for water is H_2O. The formula for sucrose, or table sugar, is $C_{12}H_{22}O_{11}$. Subscripts in chemical formulas tell you how many of each type of element are in the compound. For example, the subscript 2 in H_2O indicates that there are always two parts of hydrogen for each part of oxygen in water. Because a compound has a fixed composition, the formula for a compound is always the same.

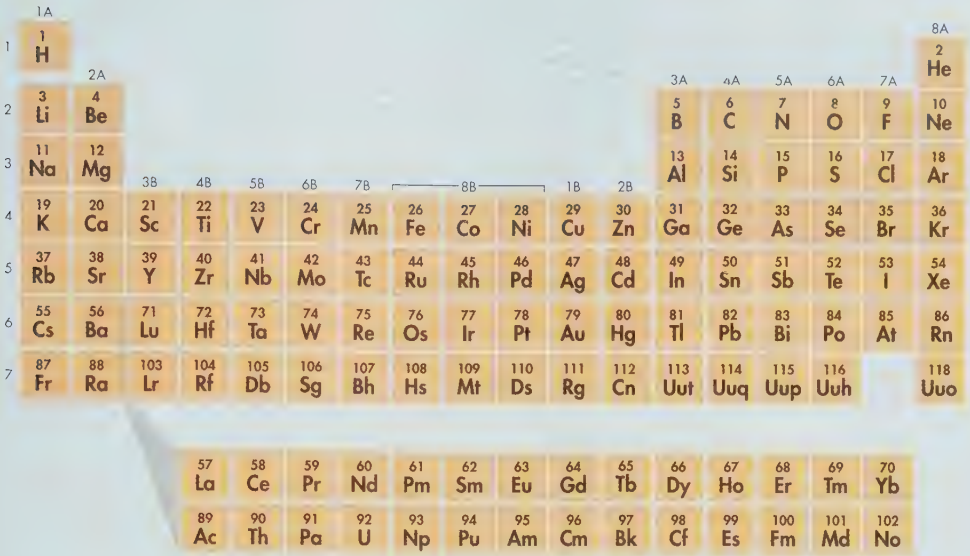
The Periodic Table—A Preview

Why is a periodic table useful?

All the known elements are organized in a special table called the periodic table. A **periodic table** is an arrangement of elements in which the elements are separated into groups based on a set of repeating properties. **The periodic table allows you to easily compare the properties of one element (or a group of elements) to another element (or group of elements).**

Figure 2.13 shows the most commonly used form of the modern periodic table, sometimes called the long form. Each element is identified by its symbol placed in a square. The elements are listed in order from left to right and top to bottom by atomic number, a number that is unique to each element. The atomic number of the element is shown centered above the symbol. You will learn more about atomic numbers in Chapter 4. Hydrogen (H), the lightest element, is in the top left corner. Helium (He), atomic number 2, is at the top right. Lithium (Li), atomic number 3, is at the left end of the second row.

Each horizontal row of the periodic table is called a **period.** There are seven periods in the periodic table. The number of elements per period ranges from 2 (hydrogen and helium) in Period 1 to 32 in Period 6. Within a period, the properties of the elements vary as you move across the period. This pattern of properties then repeats as you move to the next period.



Professional Development Note

Origins of Element Names

Many elements were named for the people who discovered them or the places where they were discovered. Some elements were given descriptive names taken from classical Latin or Greek. Others were named for figures in mythology. Polonium is named for Poland, the native land of Marie Curie, who discovered radium. Californium was discovered at the University of California. The name *chlorine* comes from the Greek *chloros*, meaning 'greenish-yellow;' it is a greenish-yellow gas. The name *calcium* is derived from the Latin *calx*, meaning 'lime'. Calcium is a major component of limestone.

Each vertical column of the periodic table is called a **group**, or family. Elements within a group have similar chemical and physical properties. Note that each group is identified by a number and the letter A or B. For example, Group 2A contains the elements beryllium (Be), magnesium (Mg), calcium (Ca), strontium (Sr), barium (Ba), and radium (Ra). You will learn more about specific trends in the periodic table in Chapter 6.

Figure 2.13 The Periodic Table
Elements are arranged in the modern periodic table in order of atomic number.
Interpret Diagrams *How many elements are in Period 2? In Group 2A?*

2.3 LessonCheck

22. Compare How is a compound different from an element?

23. Compare How can you distinguish a substance from a mixture?

24. Identify What are chemical symbols and chemical formulas used for?

25. Explain What makes the periodic table such a useful tool?

26. Identify Name two methods that can be used to break down compounds into simpler substances.

27. Classify Classify each of these samples of matter as an element, a compound, or a mixture.
a. table sugar **c.** cough syrup
b. tap water **d.** nitrogen

28. Identify Write the chemical symbol for each of the following elements:
a. lead **c.** silver **e.** hydrogen
b. oxygen **d.** sodium **f.** aluminum

29. Identify Name the chemical elements represented by the following symbols:
a. C **c.** K **e.** Fe
b. Ca **d.** Au **f.** Cu

30. Identify What elements make up the pain reliever acetaminophen, chemical formula $C_8H_9O_2N$? Which element is present in the greatest proportion by number of particles?

31. Identify Name two elements that have properties similar to those of the element calcium (Ca).

Lesson Check Answers

22. Compounds can be broken down into simpler substances by chemical means, but elements cannot.

23. A substance has a fixed composition. The composition of a mixture may vary.

24. Chemical symbols are used to represent elements. Chemical formulas are used to represent compounds.

25. It allows you to compare the properties of the elements.

26. heating or an electric current

27. **a.** compound **c.** mixture
b. mixture **d.** element

28. **a.** Pb **c.** Ag **e.** H
b. O **d.** Na **f.** Al

29. **a.** carbon **c.** potassium **e.** iron
b. calcium **d.** gold **f.** copper

30. Carbon, hydrogen, oxygen, and nitrogen; hydrogen is present in the greatest proportion by number of atoms.

31. Any two: beryllium (Be), magnesium (Mg), strontium (Sr), barium (Ba), radium (Ra).

Evaluate

Informal Assessment

Ask students to explain in their own words why a chemical change reveals that a substance is a compound. Then have students complete the 2.3 Lesson Check.

Reteach

Have students review their notes on elements, compounds, substances, and mixtures.Then, as a class, read through the flowchart in Figure 2.11. Have the class brainstorm examples of each classification and confirm their examples by using the flowchart. For any elements or compounds, have students use Table 2.2 or Figure 2.13 to identify the symbols or the words for the elements or for the elements that make up the compounds.

Answers

FIGURE 2.13 8; 6

LESSON 2.4

Key Objectives

2.4.1 DESCRIBE what happens during a chemical change.

2.4.2 IDENTIFY four possible clues that a chemical change has taken place.

2.4.3 DESCRIBE how the mass of the reactants and the mass of the products of a chemical reaction are related.

Additional Resources

Reading and Study Workbook, Lesson 2.4

Available Online or on Digital Media:

- Laboratory Manual, Labs 2 and 3
- Small-Scale Laboratory Manual, Lab 2

PearsonChem.com

Engage

CHEMISTRY & YOU Have students read the opening text and study the photograph. **Ask** What evidence do you see in the photograph that a chemical reaction has occurred? *(The burning part of the match has changed color.)*

Activate Prior Knowledge

Before students begin to read this lesson, review the concepts of physical change and chemical change. Have students predict why these concepts type of change might be related to chemical reactions.

IN ACADEMIC STANDARDS for SCIENCE

C.1.3 Recognize observable indicators of chemical changes.

C.1.4 Describe physical and chemical changes at the molecular level.

C.1.6 Explain and apply the law of conservation of mass as it applies to chemical processes.

2.4 Chemical Reactions

C.1.3 Recognize chemical changes; C.1.4 Physical and chemical changes; C.1.6 Conservation of mass: chemical changes

CHEMISTRY & YOU

Q: *What happened to the match?* Matches are often used to light candles on a cake. A match is usually lit at the tip and then burns down the match. So you better be quick, or your fingers will be burned by the lit match. A lit match is different than an unlit match. In this lesson, you will learn to recognize whether the burning match is a chemical change or physical change.

Key Questions

- ***What always happens during a chemical change?***
- ***What are four possible clues that a chemical change has taken place?***
- ***How are the mass of the reactants and the mass of the products of a chemical reaction related?***

Vocabulary

- chemical property
- chemical reaction
- reactant
- product
- precipitate
- law of conservation of mass

READING SUPPORT

Build Study Skills: *Preview Visuals* Before you start reading the lesson, preview the visuals in Figure 2.16. Then write two questions you have about the visuals. After you finish reading, answer your questions.

Chemical Changes

What always happens during a chemical change?

The compound formed when iron rusts is iron oxide (Fe_2O_3). Words such as *burn, rot, rust, decompose, ferment, explode,* and *corrode* usually signify a chemical change. The ability of a substance to undergo a specific chemical change is called a **chemical property.** Iron is able to combine with oxygen to form rust. So the ability to rust is a chemical property of iron. Chemical properties can be used to identify a substance. But chemical properties can be observed only when a substance undergoes a chemical change.

Figure 2.14 compares a physical change and a chemical change that can occur in a sample of charcoal. When charcoal is broken into smaller pieces, the change is a physical change. The substances present before the change are the same substances present after the change, although the charcoal pieces are not as large. Recall that during a physical change, the composition of matter never changes. **During a chemical change, the composition of matter always changes.** When the charcoal is heated and burned, a chemical change occurs. The substances in charcoal react with oxygen in the air to form other substances.

A chemical change is also called a chemical reaction. One or more substances change into one or more new substances during a **chemical reaction.** A substance present at the start of the reaction is a **reactant.** A substance produced in the reaction is a **product.** In the burning of charcoal, carbon and oxygen are the main reactants, and carbon dioxide is the main product.

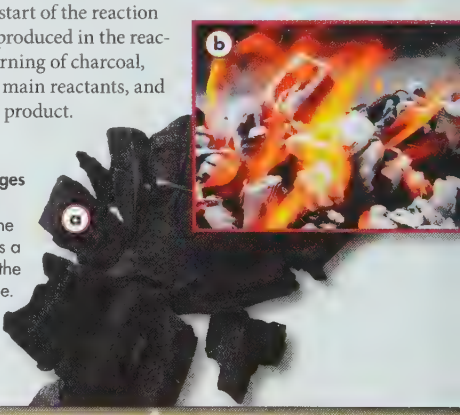


Figure 2.14
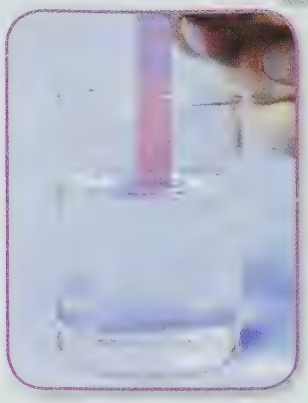
Physical and Chemical Changes
Charcoal is used as a fuel in charcoal grills. **a.** Breaking the charcoal into smaller pieces is a physical change. **b.** Burning the charcoal is a chemical change.

Focus on ELL

1 CONTENT AND LANGUAGE Write the word *reaction* on the board. Explain that this word has both common and scientific meanings. State some nonscientific examples of the word. Then have students predict the scientific meaning of the word.

2 FRONTLOAD THE LESSON Prepare a beaker of boiling water on a hot plate. Prepare a second beaker with ethanoic acid. Add a small quantity of sodium hydrogen carbonate to the ethanoic acid. Have students identify the similarities and differences between the events occurring in each beaker.



3 COMPREHENSIBLE INPUT For Figure 2.15, rewrite each caption as a word equation to reinforce that a chemical reaction is taking place in each photograph. Assist students in answering the question associated with Figure 2.16 by asking them to list the similarities and differences between the two photos.

Figure 2.15 Chemical Change
Clues to chemical change often have practical applications.

Learn more about physical and chemical changes *online.*

Production of a Gas
Bubbles of carbon dioxide gas form when two antacid tablets are dropped into a glass of water.

Color Change
When a test strip is dipped in a solution, the color change is used to determine the pH of the solution.

Formation of a Precipitate
One step in the production of cheese is a reaction that causes milk to separate into solid curds and liquid whey.

Recognizing Chemical Changes

What are four possible clues that a chemical change has taken place?

How can you tell whether a chemical change has taken place? There are four clues that can serve as a guide. **Possible clues to chemical change include a transfer of energy, a change in color, the production of a gas, or the formation of a precipitate.**

Every chemical change involves a transfer of energy. For example, energy stored in natural gas is used to cook food. When the methane in natural gas chemically combines with oxygen in the air, energy is given off in the form of heat and light. Some of this energy is transferred to and absorbed by food that is cooking over a lit gas burner. The energy causes chemical changes to take place in the food. The food may change color and brown as it cooks, which is another clue that chemical changes are occurring.

You can observe two other clues to chemical change while cleaning a bathtub. The ring of soap scum that can form in a bathtub is an example of a precipitate. A **precipitate** is a solid that forms and settles out of a liquid mixture. Some bathroom cleaners that you can use to remove soap scum start to bubble when you spray them on the scum. The bubbles are produced because a gas is released during the chemical change that is taking place in the cleaner.

If you observe a clue to chemical change, you cannot be certain that a chemical change has taken place. The clue may be the result of a physical change. For example, energy is always transferred when matter changes from one state to another. Bubbles form when you boil water or open a carbonated drink. The only way to be sure that a chemical change has occurred is to test the composition of a sample before and after the change. Figure 2.15 shows examples of practical situations in which different clues to chemical change are visible.

CHEMISTRY & YOU

Q: *Are the changes that happen to a burning match chemical changes or physical changes? How do you know?*

Focus on ELL

4 LANGUAGE PRODUCTION Have students work in groups of four to complete the lab on page 51. Make sure each group has ELLs of varied language proficiencies so that more proficient students can help less proficient ones. Have students work according to their proficiency level.

BEGINNING: LOW/HIGH Provide students with colored markers to use to indicate their observations.

INTERMEDIATE: LOW/HIGH Provide students with a checklist they can use to better guide them through the procedure. Have students verbally respond to the Analyze questions.

Foundations for Reading

BUILD VOCABULARY Ask a student volunteer to explain the term *precipitation*. Point out that just as precipitation falls from the sky, a *precipitate* "falls" out of solution.

READING STRATEGY Preview the lesson by having students examine the photographs and diagrams and read the related captions. Encourage students to predict the answers to the questions presented in the captions.

Explain

Chemical Changes

CHEMISTRY & YOU Chemical changes; clues include a transfer of energy (heat is produced), production of a gas (smoke is produced), and a color change (the match darkens).

Explore

Recognizing Chemical Changes

Teacher Demo

PURPOSE Students will practice identifying chemical changes.

MATERIALS Bunsen burner, match, tongs, magnesium ribbon, 4 test tubes, solutions of 0.1*M* $AgNO_3$, 0.1*M* NaCl, 0.1*M* K_2CrO_4, and 3*M* H_2SO_4, mossy zinc, marble chip, spatulas, cobalt blue glass filters

SAFETY For Step c, wear gloves to avoid stains on your skin from silver nitrate.

CAUTION Students should not look at burning magnesium without the cobalt blue glass filters.

PROCEDURE As you do each step, have students identify the clues for chemical change. Emphasize that the clues point to a chemical change but do not confirm that a change has taken place.

a. Light a Bunsen burner. *(Heat and light are produced.)*

b. Using tongs, hold a piece of magnesium ribbon in a burner flame until it ignites. Remove from heat and observe. *(The product is a white powder; heat and light are produced.)*

c. Put 5 mL of silver nitrate solution in each of two test tubes. Add a small amount of sodium chloride solution to one tube and potassium chromate solution to the other. *(color change, formation of a precipitate)*

d. Put 5 mL of sulfuric acid in each of two test tubes. Add a piece of mossy zinc to one tube and a marble chip ($CaCO_3$) to the other. *(formation of a gas)*

Explain

Conservation of Mass

USE VISUALS Direct students' attention to Figure 2.16. Explain that the photos are before and after views of a reaction. **Ask** Why are the containers covered? *(The covers prevent evaporation of the solutions and loss of mass.)*

Evaluate

Informal Assessment

Write this word equation on the board:

methane + oxygen → carbon dioxide + water + energy

Have students identify the reactants and products and one possible clue for a chemical change. Then have students complete the 2.4 Lesson Check.

Reteach

Write a word equation on the board for the reaction of magnesium and oxygen to produce magnesium oxide. **Ask** How is mass conserved in this reaction? *(The difference between the mass of the magnesium and the mass of the magnesium oxide is the mass of the oxygen with which the magnesium combines.)*

Conservation of Mass

How are the mass of the reactants and the mass of the products of a chemical reaction related?

When wood burns, substances in the wood combine with oxygen from the air. As the wood burns, a sizable amount of matter is reduced to a small pile of ashes. The reaction seems to involve a reduction in the amount of matter. But appearances can be deceiving. **During any chemical reaction, the mass of the products is always equal to the mass of the reactants.** Two of the products of burning wood—carbon dioxide gas and water vapor—are released into the air. When the mass of these gases is considered, the amount of matter is unchanged. Careful measurements show that the total mass of the reactants (wood and the oxygen consumed) equals the total mass of the products (carbon dioxide, water vapor, and ash).

Mass also holds constant during physical changes. For example, when 10 grams of ice melt, 10 grams of liquid water are produced. Similar observations have been recorded for all chemical and physical changes studied. The scientific law that reflects these observations is the law of conservation of mass. The **law of conservation of mass** states that in any physical change or chemical reaction, mass is conserved. Mass is neither created nor destroyed. The conservation of mass is more easily observed when a change occurs in a closed container, as in Figure 2.16.

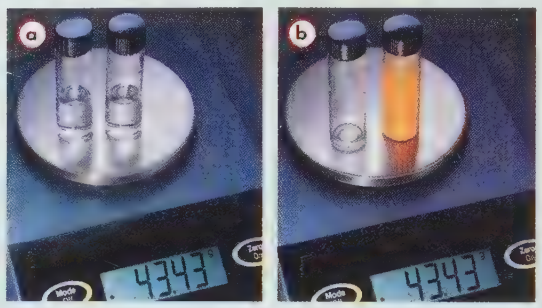


Figure 2.16
Conservation of Mass
When the liquids in **a.** are mixed, they react. None of the products are gases.
Analyze Data ***How do you know that a reaction took place and that mass was conserved during the reaction?***

2.4 LessonCheck

32. Explain How does a chemical change affect the composition of matter?

33. List Name four possible clues that a chemical change has taken place.

34. Compare In a chemical reaction, how does the mass of the reactants compare with the mass of the products?

35. Compare What is the main difference between physical changes and chemical changes?

36. Classify Classify the following changes as physical or chemical changes.
a. Water boils. **c.** Milk turns sour.
b. Salt dissolves in water. **d.** A metal rusts.

37. Explain According to the law of conservation of mass, when is mass conserved?

38. Calculate Hydrogen and oxygen react chemically to form water. How much water would form if 4.8 grams of hydrogen reacted with 38.4 grams of oxygen?

Lesson Check Answers

32. The composition of matter always changes during a chemical change.

33. a transfer of energy, a change in color, the production of a gas, the formation of a precipitate

34. The mass of the products is always equal to the mass of the reactants.

35. In a physical change, the chemical composition of a substance does not change. In a chemical change, the chemical composition of the reactants changes as one or more products form.

36. **a.** physical **c.** chemical
b. physical **d.** chemical

37. Mass is conserved in every physical change or chemical reaction.

38. 43.2 g

Small-Scale Lab

1 + 2 + 3 = Black!

Purpose

To make macroscopic observations of chemical reactions and use them to solve problems

Materials

- paper
- metric ruler
- reaction surface
- materials shown in grid
- pipette, medicine droppers, and spatulas

Procedure

1. Draw two copies of the grid on separate sheets of paper. Make each square in the grid 2 cm on each side.
2. Place a reaction surface over one of the grids. Use the second grid as a data table to record your observations.
3. Use the column and row labels to determine which materials belong in each square. Depending on the material, add one drop, one piece, or a few grains.
4. Stir each mixture by forcing air from an empty pipette as directed by your teacher.

	NaClO	H_2O_2	$CuSO_4$
KI			
KI + Starch			
KI + Paper			
KI + Cereal			

Analyze

Using your experimental data, record the answers to the following questions below your data table.

1. **Describe** What color is a mixture of sodium hypochlorite (NaClO) and potassium iodide (KI)?
2. **Describe** What happens when you mix NaClO, KI, and starch?
3. **Compare** What do NaClO, H_2O_2, and $CuSO_4$ have in common?
4. **Compare** What substance is found in both paper and cereal? How do you know?
5. **Predict** If you used NaClO instead of $CuSO_4$ in reactions other than the reaction with KI and starch, would you expect the results to always be identical? Explain your answer.

You're the Chemist

The following small-scale activities allow you to develop your own procedures and analyze the results.

1. **Analyze Data** NaClO is a bleaching agent. Such agents are used to whiten clothes and remove stains. Use different color marker pens to draw several lines on a piece of white paper. Add one drop of NaClO to each line. What happens? Try inventing a technique that you can use to make "bleach art."
2. **Design an Experiment** Design and carry out an experiment to see which foods contain starch.
3. **Design an Experiment** Read the label on a package of iodized salt. How much KI does iodized salt contain? Design an experiment to demonstrate the presence of KI in iodized salt and its absence in salt that is not iodized.
4. **Design an Experiment** Antacid tablets often contain starch as a binder to hold the ingredients in the tablet together. Design and carry out an experiment to explore various antacid tablets to see if they contain starch.

5. The results may be the same in reactions that are similar to the one with KI and starch but different in other reactions.

YOU'RE THE CHEMIST

1. The color fades. A picture can be drawn with colored ink. Areas can be treated with NaClO to bleach parts of the picture.
2. Add KI + NaClO to various foods. A black color indicates the presence of starch.
3. Most table salt contains 0.01% KI. Wet only a portion of a small pile of salt with starch. Add $CuSO_4$ or H_2O_2. A black color indicates the presence of KI.
4. If an antacid tablet contains starch, it will turn black when treated with KI + NaClO.

Small-Scale Lab

OBJECTIVE In this activity, students will begin to familiarize themselves with small-scale equipment and methodology. They will also observe and analyze some chemical reactions

SKILLS FOCUS Observing, classifying

PREP TIME 1 hour

CLASS TIME 40 minutes

MATERIALS paper, metric ruler, reaction surface, pipette, dropper, spatulas, KI, liquid starch, cereal, NaClO, H_2O_2, $CuSO_4$, foods, iodized and non-iodized salt, antacid tablets, color marker pens

ADVANCE PREPARATION

Solution	Preparation
0.1*M* KI	4.2 g KI in 250 mL water
0.2*M* $CuSO_4$	12.5 g $CuSO_4 \cdot 5H_2O$ in 250 mL water
1% NaClO	50 mL household bleach in 200 mL water
3% H_2O_2	Use undiluted household hydrogen peroxide
20% starch	50 mL liquid starch in 200 mL water

TEACHING TIPS Demonstrate how to use a pipette as a stirrer. This information, as well as a discussion of reaction surfaces, can be found in the *Small-Scale Chemistry Laboratory Manual.* Explain that using a mixture of KI and NaClO to test for starch is an example of qualitative analysis.

EXPECTED OUTCOME

	NaClO	H_2O_2	$CuSO_4$
KI	yellow	yellow	brown ppt
KI + starch	black	black	black
KI + paper	black	black	black
KI + cereal	black	black	black

FOR ENRICHMENT Have students design and carry out an experiment to quantify the amount of KI in iodized salt.

ANALYZE AND CONCLUDE

1. yellow
2. The mixture turns a blue-black color.
3. They all turn a mixture of KI and starch black.
4. Starch; both turn blue-black, which suggests the presence of starch.

Answers

FIGURE 2.16 Change of color and formation of a precipitate; the balance reading did not change.

CHEMISTRY & YOU Draw students' attention to the container of recyclables in the photo. Point out that most communities and businesses now actively participate in recycling, particularly of glass, paper, and plastic products. Explain that recycling guidelines vary from municipality to municipality, depending upon how the garbage/recyclables collection process is set up in their community. Some cities might mandate recycling as a part of city-wide garbage pickup. Other communities might rely on private haulers to collect garbage and recyclables.

Engage students in a discussion of the types of recycling they commonly do in their homes or workplaces, and create a list of the types of recyclables their hauler will accept. For example, some waste management authorities will accept only glass, metal cans, certain plastics, and newspapers. Others might accept these items as well as pasteboard, cardboard, and magazines. Still other communities accept all of the previously mentioned items as well as used motor oil, lead batteries, and appliances.

Pose the following question to students: *What factors determine they types of materials that a community waste management authority or private hauler collects for recycling?*

You may need to guide students in the following ways:

- Some recycled materials have stronger market demands than other materials.
- Certain materials, such as used motor oil and lead batteries, are or contain environmental hazards.
- Equipment upgrades are often necessary if a new type of recyclable is added to the list or if the collection method changes from drop-off centers to curbside recycling.

21st Century Learning To be successful in the 21st century, students need skills and learning experiences that extend beyond subject matter mastery. This project helps students build the following 21st Century Skills: *Global Awareness; Financial, Economic, Business and Entrepreneurial Literacy; Critical Thinking and Problem Solving; Communication and Collaboration; Information Literacy; Media Literacy; Productivity and Accountability.*

BUILD A COMPOST PILE Pose the following challenge to your students. *A rural community in your state has received a grant to begin a recycling program, and approaches your company to develop a recycling plan.* Form a "company" of four to six students to develop a plan that is suited to a rural community with a widely dispersed population and present your plan as an audio slideshow on digital media. Plans should include a determination as to whether curbside or drop-off recycling is most appropriate for the community, a comparison of the types of sorting systems available, a list of the most accessible markets for recycled materials, and a determination of the financial and environmental impact of enacting the plan.

Take It Further

1. Identify What are three properties of matter that are used to help sort materials during the single-stream recycling process?

2. Describe What are some possible benefits of single-stream recycling vs. regular recycling?

7. BALERS After the products are separated, they're stored and fed into balers, which bundle the materials together. The materials are then shipped out to recycling plants, where they will be made into new products.

Differentiated Instruction

L1 ENGLISH LANGUAGE LEARNERS Have students translate the words *recycle, compost, plastic,* and *landfill* into their native language and teach the class how to pronounce each word. As a class use creative ways such as act it out or photographs to teach the meaning of these words.

LPR LESS PROFICIENT READERS Divide the class into groups of 3 to 4 students. Have students independently read a paragraph or caption on the page and then discuss it with others in their group. Then have them independently write a sentence summarizing what they have read. Repeat for the remaining paragraphs and captions.

L3 ADVANCED STUDENTS Provide students with a list of plastic recycling codes. Have students choose one type of plastic from the list and research the specific method used to recycle it. Then have them make a small poster explaining the method. Students should include details about physical and chemical changes used in the recycling process as well as an economic summary outlining cost associated with the process.

Explain

START A CONVERSATION Engage students in a conversation of the different methods of recycling. Have them consider the steps needed to recycle different materials. Point out the following:

- Soda cans are an alloy (homogeneous mixture) of metals, but the tops do not have the same percentages of metals as the rest of the can. After the can is melted, more of some metals must be added before using the recycled metal to make new cans.
- One of the misconceptions of recycling is that paper products degrade quickly in a landfill. In fact, all products degrade slowly because it is an anaerobic (low oxygen) environment.
- Yard trimmings should not be placed in garbage that will go to landfills because they take up so much room. Instead, yard trimmings are easily composted.

Extend

Connect to BIOLOGY Remind students that decomposers are nature's recyclers. Explain to students that vermicomposting is a type of composting that uses worms to break down yard and food wastes. Explain that worms placed in a compost pile eat and digest the materials, and then excrete a nutrient-rich soil. Have students determine the physical and chemical changes in the materials. *(Physical change: During digestion, the food passes through the worm's gizzard where stones the worm has previously ingested grind the food into smaller pieces. Chemical change: The food then moves into the intestine where it is chemically broken down.)*

Answers

TAKE IT FURTHER

1. Magnetism, color, conductivity.
2. Single-stream recycling makes recycling easier and more convenient, so people may be more likely to recycle. Single-stream recycling centers may accept more types of materials for recycling.

STUDY GUIDE

Evaluate

Review and Assessment Materials

PROBLEM SETS Have students practice more chemical quantity problems by using the Chapter 2 Online Problem Set.

MATH SKILLS REVIEW Have struggling students practice solving algebraic equations by using the MathXL learning module.

VIRTUAL LABS Have students complete a virtual lab as an in-class or take-home assignment to help reinforce the concepts involved in recognizing signs of chemical change.

Study Tip

ORGANIZE NEW INFORMATION Have students learn new vocabulary terms by making vocabulary flashcards. Students should write a vocabulary term on one side of a card and its definition on the other side. The cards can be used by students to quiz each other.

UbD

Understanding by Design

Performance Tasks

SECRET MATTER Direct students to create a secret mixture and record the items used in the mixture. Have students exchange mixtures with a partner. Students should determine a method to separate their partner's mixture into its various components. Have students submit their findings and written descriptions of the substance properties and the processes used to separate the mixture, along with a copy of the ingredient list for the mixture they created.

MATTER OF FACT! Have students create and perform a science experiment about physical and chemical changes. Students should submitte a written report that includes the purpose, the materials, the procedure, the expected outcome, safety issues, and an Analyze and Conclude question section. The procedure should demonstrate at least one physical change and at least one chemical change.

2 Study Guide

BIGIDEA

CHEMISTRY AS THE CENTRAL SCIENCE

Physical properties, such as melting point and boiling point, and chemical properties, such as whether a substance will corrode or burn, are used to describe matter. Matter may be made of elements or compounds. Elements and compounds are pure substances but can be physically combined to make heterogenous or homogeneous mixtures. These different forms of matter may undergo physical or chemical changes.

2.1 Properties of Matter

- Every sample of a given substance has identical intensive properties because every sample has the same composition.
- Three states of matter are solid, liquid, and gas.
- Physical changes can be classified as reversible or irreversible.

- mass (34)
- volume (34)
- extensive property (34)
- intensive property (34)
- substance (35)
- physical property (35)
- solid (36)
- liquid (36)
- gas (37)
- vapor (37)
- physical change (37)

2.2 Mixtures

- Mixtures can be classified as heterogeneous mixtures or as homogeneous mixtures, based on the distribution of their components.
- Differences in physical properties can be used to separate mixtures.

- mixture (38)
- heterogeneous mixture (39)
- homogeneous mixture (39)
- solution (39)
- phase (39)
- filtration (40)
- distillation (40)

2.3 Elements and Compounds

- Compounds can be broken down into simpler substances by chemical means, but elements cannot.
- If the composition of a material is fixed, the material is a substance. If the composition may vary, the material is a mixture.
- Chemists use chemical symbols to represent elements, and chemical formulas to represent compounds.
- The periodic table allows you to easily compare the properties of one element (or a group of elements) to another element (or group of elements).

- element (42)
- compound (42)
- chemical change (43)
- chemical symbol (45)
- periodic table (46)
- period (46)
- group (47)

2.4 Chemical Reactions

- During a chemical change, the composition of matter always changes.
- Four possible clues to chemical change include a transfer of energy, a change in color, the production of a gas, or the formation of a precipitate.
- During any chemical reaction, the mass of the products is always equal to the mass of the reactants.

- chemical property (48)
- chemical reaction (48)
- reactant (48)
- product (48)
- precipitate (49)
- law of conservation of mass (50)

FOCUS ON ELL

5 ASSESS UNDERSTANDING Have ELL students keep a content log to track their progress during this chapter. Provide suggestions for the log and follow up often with students to determine the material that needs further explanation.

BEGINNING: LOW/HIGH Provide students with two colors of small sticky notes, one color indicating they understand a topic, the other color indicating that they do not understand the topic. Have students mark each major section with the appropriately colored sticky note. Review areas of concern with students.

INTERMEDIATE: LOW/HIGH Provide students with a two-column chart with headings that read *What I Understand* and *What I Do Not Understand*. Have students complete the chart by using symbols, page numbers, simple sentences, or their native languages.

ADVANCED: LOW/HIGH Group students in small topic circles and lead a discussion of the common areas of struggle. Allow extra time for ELL students to explain or to show the concepts requiring additional help.

2 Assessment

* Solutions appear in Appendix E

Lesson by Lesson

2.1 Properties of Matter

39. Describe the difference between an extensive property and an intensive property and give an example of each.

40. List three physical properties of copper.

41. Name two physical properties that could be used to distinguish between water and ethanol.

***42.** Name one physical property that could not be used to distinguish chlorine from oxygen.

43. What is the physical state of each of these materials at room temperature?

a. gold
b. gasoline
c. oxygen
d. neon
e. olive oil
f. sulfur
g. mercury

***44.** Fingernail-polish remover (mostly acetone) is a liquid at room temperature. Would you describe acetone in the gaseous state as a vapor or a gas? Explain your answer.

45. Compare the arrangements of individual particles in solids, liquids, and gases.

46. Use Table 2.1 to identify four substances that undergo a physical change if the temperature is reduced from 50°C to −50°C. What is the physical change that takes place in each case?

***47.** Explain why sharpening a pencil is a different type of physical change than freezing water to make ice cubes.

2.2 Mixtures

48. What is the difference between homogeneous mixtures and heterogeneous mixtures?

49. How many phases does a solution have? Explain your answer.

***50.** Classify each of the following as a homogeneous or heterogeneous mixture.

a. chocolate-chip ice cream
b. green ink
c. cake batter
d. cooking oil
e. granite rock
f. salt water
g. paint
h. a silver ring

51. What is the goal of a distillation? Describe briefly how this goal is accomplished.

2.3 Elements and Compounds

52. How could you distinguish an element from a compound?

***53.** Classify the following materials as an element, compound, or mixture. Give reasons for your answers.

a. table salt (NaCl)
b. salt water
c. sodium (Na)

54. Describe the relationship between the three items in each of the following groups. Identify each item as an element, compound, or mixture.

a. hydrogen, oxygen, and water
b. nitrogen, oxygen, and air
c. sodium, chlorine, and table salt
d. carbon, water, and table sugar

55. Name the elements found in each of the following compounds.

a. ammonia (NH_3)
b. potassium oxide (K_2O)
c. sucrose ($C_{12}H_{22}O_{11}$)
d. calcium sulfide (CaS)

56. Not all element names come from English or Latin words. The symbol for tungsten is W from the German word *wolfram*. The symbol for mercury is Hg from the Greek word *hydragyrum*. Use the symbols W and Hg to explain the system of symbols for elements.

***57.** What does the formula H_2O tell you about the composition of water?

54. Hydrogen and oxygen are the elements that make up the compound water.
b. Nitrogen and oxygen are elements present in the mixture air.
c. Sodium and chlorine are elements in the compound sodium chloride (table salt).
d. The element carbon and the compound water are the final products of heating table sugar.

55. **a.** nitrogen, hydrogen **b.** potassium, oxygen **c.** carbon, hydrogen, oxygen **d.** calcium, sulfur

56. In W, the single letter is capitalized. In Hg, the first letter is a capital and the second letter is lowercase.

57. The compound water contains two parts hydrogen to one part oxygen.

Evaluate

Answers

LESSON 2.1

39. An extensive property depends on the amount of matter; an intensive property depends on the type of matter. Mass and volume are extensive properties. Color and hardness are intensive properties.

40. Answers could include reddish-yellow color, conductor of heat and electricity, malleable, melting point of 1084°C, and boiling point of 2562°C.

41. melting point and boiling point

42. State; both are gases.

43. **a.** solid **b.** liquid **c.** gas **d.** gas **e.** liquid **f.** solid **g.** liquid

44. A vapor; the term *vapor* is used to refer to the gaseous state of a substance which normally exists as a liquid or solid at room temperature.

45. The particles in a solid are packed tightly together in an orderly arrangement. Particles in a liquid are in close contact, but not in a orderly arrangement. The particles in a gas are relatively far apart.

46. Chlorine condenses. Mercury, bromine and water freeze.

47. Sharpening a pencil is an irreversible change. Making ice cubes is a reversible change.

LESSON 2.2

48. Heterogeneous mixtures have a non-uniform composition with two or more phases. Homogeneous mixtures have a uniform composition.

49. one; Solutions are homogeneous mixtures with uniform composition throughout.

50. **a.** heterogeneous **b.** homogeneous **c.** depends on how well the batter is mixed **d.** homogeneous **e.** heterogeneous **f.** homogeneous **g.** heterogeneous **h.** homogeneous

51. The goal is to separate the components of a solution. The solution is boiled to produce a vapor, which is condensed to a liquid. Dissolved solids are left behind.

LESSON 2.3

52. Compounds can be separated by chemical means into simpler substances. Elements cannot.

53. **a.** Compound; formula indicates its made of more than one element, but only one compound so its not a mixture. **b.** Mixture; made of two compounds, salt and water. **c.** Element; formula indicates its made of only one element.

ASSESSMENT

Evaluate

Answers

58. Sample answer: The table is set up so that chemical properties of elements recur at regular intervals.

LESSON 2.4

59. When heated, sulfur and iron react and form iron sulfide. The composition of the reactants in a chemical change is different from the composition of the products. In a physical change, the chemical composition of a sample doesn't change.

60. **a.** physical **b.** chemical (color change) **c.** chemical (production of a gas) **d.** physical

61. chemical property

62. 18 g of water

UNDERSTAND CONCEPTS

63. ethanol

64. neon

65. sulfur

66. sulfur

67. Mass is an extensive property, which depends only on the amount of matter in the sample, not on the composition of the sample.

68. Malleability is an intensive property, which depends on the type of matter in a sample.

70. The particles in solids are packed tightly together. The particles in a gas are spaced relatively far apart.

71. kitchen, mixtures; park, mixtures

72. **a.** heterogeneous mixture
b. compound
c. homogeneous mixture
d. heterogeneous mixture

73. **a.** physical **c.** physical **e.** chemical
b. physical **d.** physical

74. **a.** Both are elements and solids at room temperature; they are a different color and have different melting points and boiling points.
b. Both are clear liquids at room temperature; distilled water is an element and saltwater is a mixture.
c. Both are white, solid compounds. Sugar is composed of carbon, hydrogen, and oxygen. Salt is composed of sodium and chlorine.

75. **a.** element **c.** mixture **e.** mixture
b. compound **d.** element **f.** compound

58. Look up the word *periodic* in the dictionary. Propose a reason for the naming of the periodic table.

2.4 Chemical Reactions

59. Use the word equation below to explain how a chemical change differs from a physical change.

$$\text{iron} + \text{sulfur} \xrightarrow{\text{heat}} \text{iron sulfide}$$

***60.** Classify each of the following as a physical or chemical change. For any chemical change, list at least one clue to support your answer.
a. A copper wire is bent.
b. Charcoal burns in a grill.
c. Bread dough rises when yeast is added.
d. Sugar dissolves in water.

61. Which type of property cannot be observed without changing the composition of a substance?

***62.** When ammonium nitrate (NH_4NO_3) explodes, the products are nitrogen, oxygen, and water. When 40 grams of ammonium nitrate explode, 14 grams of nitrogen and 8 grams of oxygen form. How many grams of water form?

Understand Concepts

Use the data table to answer Questions 63–66.

Substance	Color	Melting point (°C)	Boiling point (°C)
Bromine	Red-brown	−7	59
Chlorine	Green-yellow	−101	−34
Ethanol	Colorless	−117	78
Mercury	Silvery-white	39	357
Neon	Colorless	−249	−246
Sulfur	Yellow	115	445
Water	Colorless	0	100

63. Which colorless substance is a liquid at −30°C?

64. Which colorless substance is a gas at 60°C?

65. Which substance is a solid at 7°C?

***66.** As the temperature rises, which solid will melt before mercury boils?

***67.** Explain why mass cannot be used as a property to identify a sample of matter.

68. Is malleability an extensive property or an intensive property? Explain.

69. The state of a substance can change when the substance is heated or cooled. So what does it mean to say that a certain substance is a solid, liquid, or gas?

***70.** Use the arrangement of particles in solids and gases to explain why solids are not as easy to compress as gases.

71. You are standing in a kitchen and then in the middle of a park. When you view your surroundings in each location, do you see mostly elements, compounds, or mixtures?

72. Identify each of the following items as a mixture or compound. Classify the mixtures as homogeneous or heterogeneous.
a. raw egg
b. ice
c. gasoline
d. blood

73. Classify the following properties of the element silicon as chemical or physical properties:
a. blue-gray color
b. brittle
c. doesn't dissolve in water
d. melts at 1410°C
e. reacts vigorously with fluorine

74. How are the items in each of the following pairs similar? How are they different?
a. copper and silver
b. distilled water and salt water
c. table sugar and table salt

75. Identify each of the following as an element, compound or mixture.
a. iron
b. distilled water
c. laundry detergent
d. sulfur
e. chicken broth
f. sodium fluoride

*76. Describe clues you might observe during the following events that could support the conclusion that a chemical change is occurring.
   a. An antacid tablet is dropped into water.
   b. A ring of scum forms around a bathtub.
   c. Iron rusts.
   d. A firecracker explodes.
   e. Bubbles form when hydrogen peroxide is poured onto an open wound.
   f. A hamburger cooks.

77. In photograph A, a coil of zinc metal is in a solution of sulfuric acid. In photograph B, a yellow solution of sodium chromate is being added to a colorless solution of silver nitrate. What clues in the photographs indicate that a chemical change is probably occurring?

A. 

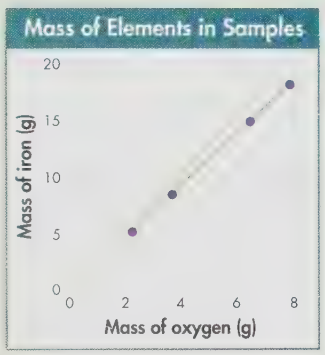
B. 

78. Classify each of the following as a chemical change or a physical change.
   a. Plastic drink bottles are burned in an incinerator to generate electricity.
   b. Digesting a cereal bar.
   c. Water in a rain puddle evaporates.
   d. Slicing a tomato for a sandwich.
   e. Plastic drink bottles are recycled to make fiberfill for ski jackets.

79. Explain why the production of a gas does not always mean that a chemical reaction has occurred.

*80. The wax seems to disappear as a candle burns. How can the law of conservation of mass apply to this reaction?

Think Critically



*81. **Apply Concepts** Devise a way to separate sand from a mixture of charcoal, sand, sugar, and water.

82. **Sequence** Assume that water, mercury, and gallium are all at 40°C. As the temperature drops, which substance will freeze first? Which will be the last to freeze?

83. **Apply Concepts** A change in odor can also be a clue that a chemical change has occurred. Describe at least one situation in which you might be likely to detect such a change in odor in a kitchen.

84. **Explain** Explain why this statement is false. "Because there is no change in composition during a physical change, the appearance of the substance will not change."

*85. **Interpret Graphs** The mass of the elements iron and oxygen in four samples of a rust-colored substance was measured in grams (g). The amount of iron and oxygen in each sample is shown on the graph.

   a. Do you think all four samples are the same compound? Explain.
   b. Another sample of similar material was found to contain 9.9 grams of iron and 3.4 grams of oxygen. Is this sample the same substance as the other four samples? Explain.

86. **Explain** When powdered iron is left exposed to the air, it rusts. Explain why the mass of the rust is greater than the mass of the powdered iron.

87. **Explain** Discuss the statement "A gas requires a container, but a solid is its own container."

ASSESSMENT

Evaluate

Answers

76. **a.** gas is produced.
b. formation of a precipitate
c. color and texture change
d. energy change, odor change
e. gas is produced
f. energy change, color change, odor change

77. In photograph A, bubbles indicate the production of a gas. In photograph B, there is a color change and a precipitate.

78. **a.** chemical **c.** physical **e.** physical
b. chemical **d.** physical

79. A gas may be released during a physical change. For example, bubbles form when water boils.

80. The wax appears to disappear because the products of the reaction—carbon dioxide and water vapor—are colorless gases.

THINK CRITICALLY

81. Add sufficient water to dissolve all of the sugar. Separate the charcoal and sand from the sugar water by filtration. Large pieces of charcoal could be separated on the basis of color. Small pieces of charcoal could be burned.

82. Gallium (c) will freeze first; mercury (b) will freeze last.

83. Smelling something burning is one possible answer.

84. The appearance of a substance will change during a change of state, which is a physical change.

85. **a.** Yes; because the graph is a straight line, the proportion of iron to oxygen is a constant, which is true for a compound.
b. No; a point for the values given wouldn't fall on the line. The mass ratio of iron to oxygen is different.

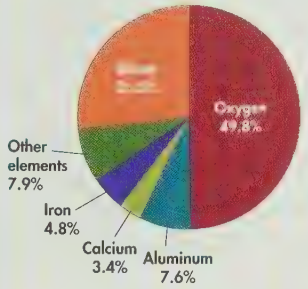
86. Iron rusts when it reacts with oxygen in the air to form an oxide (Fe_2O_3). The mass of the rust is the sum of the mass of the iron and the mass of the oxygen that combined with the iron.

87. A gas expands to fill any space; a gas has no shape or volume without a container. A solid has a definite shape and volume; a solid doesn't need a container to maintain its shape and volume.

CHEMYSTERY **START A CONVERSATION** After students have read through the CHEMystery, call on volunteers to describe how matter changes in each of the three scenarios. **Ask** How can you determine whether a change is physical or chemical? *(You consider whether the composition of matter is the same before and after the change. If the composition changes, matter has changed chemically.)*

Have students think about water boiling to form water vapor. **Ask** Is the formation of bubbles always a sign that a physical change is occurring? *(no)* **Ask** What is an example of bubbles occurring during a chemical change? *(Sample answer: Bubbles might form during the production of a gas, as when vinegar and baking soda react.)*

Have students think about leaves changing color in the fall. **Ask** Is color change always a sign that a chemical change is occurring? *(no)* **Ask** What is an example of a color change during a physical change? *(Sample answer: You can change the color of your room by painting it.)* Point out that even though paint is a chemical substance, the color change of the wall is not the result of a chemical reaction between the new paint and the old paint. The change occurs because a new mixture of pigments is applied to the wall.



CHEMYSTERY ANSWERS

94. The physical changes are reversible. The water in the geyser can change from steam to liquid water and the water in the glacier can freeze and melt.

95. **BIG**IDEA If rangers have knowledge of physical and chemical changes then they will have a better understanding of the changes they see occurring in the park. This might help them assess whether the changes are normal or possibly harmful.

Enrichment

*88. **Interpret Graphs** Five elements make up 98% of the mass of the human body. These elements are oxygen (61%), carbon (23%), hydrogen (10.0%), nitrogen (2.6%), and calcium (1.4%). Compare these data with those in the pie graph below, which shows the five most abundant elements by mass in Earth's crust, oceans, and atmosphere.

a. Which elements are abundant both in the human body and Earth's crust, oceans, and atmosphere?
b. Which elements are abundant in Earth's crust, oceans, and atmosphere, but not in the human body?
c. Would you expect the compounds found in the human body to be the same as or different from those found in rocks, seawater, and air? Use the data to explain your answer.

89. Evaluate Each day you encounter some chemical changes that are helpful and some that are harmful to humans or the environment. Cite three examples of each type. For each example, list the clues that identified the change as a chemical change.

90. Interpret Tables Use Table 2.1 on page 35 to answer this question.
a. Which substances in the table are in the liquid state at 125°C?
b. Use the physical properties of one of these substances to explain how you figured out the answer to Question 90a.
c. The substances in the table are listed in order of increasing melting point. Propose another way that these data could be arranged.

Write About Science

91. Explain Write a paragraph in support of this statement: "Dry tea is a mixture, not a substance." Include at least two pieces of evidence to support your argument.

92. Explain Lavoisier proposed the law of conservation of mass in 1789. Write a paragraph describing, in general, what Lavoisier must have done before he proposed this law. Use what you have learned about the scientific method.

93. Connect to the **BIG**IDEA Compare elements and compounds by saying how they are alike. Contrast elements and compounds by describing how they are different.

CHEMYSTERY

Which One Is Not Like the Others?

The eruption of geysers in Yellowstone National Park is caused by a physical change. Underground water is heated to temperatures hot enough to turn the water into steam. This steam causes an increase in pressure underground. In the cases of geysers, the steam is at first unable to escape. But, when the pressure reaches a critical level, an eruption occurs, producing the geyser.

The shaping of valleys by melt-refreeze cycles is also a physical change. The melting and refreezing of water is a physical change, and as the earth underneath the glacier is broken apart and moved, this is also a physical change.

The changing of the color of leaves is a chemical change. As the temperature and hours of sunlight change in the fall, chemical changes occur. Therefore, leaves changing color, a chemical change, is not like the physical changes of geysers erupting or glaciers moving.

94. Identify Are the physical changes in the mystery reversible or irreversible physical changes? Explain your answer.

95. Connect to the **BIG**IDEA Why would it be important for rangers at national parks to have knowledge of physical and chemical changes?

ENRICHMENT

88. **a.** oxygen and calcium
b. silicon, aluminum, and iron
c. Different; the second most abundant element in Earth's crust, silicon, is not present in the human body, and the second most abundant element in the human body, carbon, is not among the most abundant elements in Earth's crust. If the elements are different, then the compounds must also be different.

89. Many answers are possible. Cooking food (color change, odor change) is an example of a helpful change; the burning of gasoline in a gasoline engine (production of a gas, energy change) is an example of a harmful change.

90. **a.** mercury and sulfur
b. Sulfur melts at 113°C and boils at 445°C. Between 113°C and 445°C, it exists as a liquid. Mercury melts at −39°C and boils at 357°C. Between these temperatures, it exists as a liquid.
c. Possibilities include: by color, by boiling point, or in alphabetical order.

WRITE ABOUT SCIENCE

91. Answers will vary. Possible evidence includes the fact that only some substances in the tea dissolve in water, and tea is sold both with and without caffeine.

92. Before he proposed the law of conservation of mass, Lavoisier would have done a series of experiments in which he measured the masses of reactants and products.

93. Elements and compounds are alike in that they both are substances of fixed composition. They are different in that elements cannot be separated into simpler substances through chemical changes.

Standardized Test Prep for Indiana

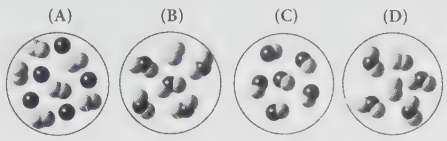
Standards: C.1.1, C.1.5

Select the choice that best answers each question or completes each statement.

1. Which of the following is not a chemical change?
   (A) paper being shredded
   (B) steel rusting
   (C) charcoal burning
   (D) a newspaper yellowing in the sun
2. Which phrase best describes an apple?
   (A) heterogeneous mixture
   (B) homogeneous compound
   (C) heterogeneous substance
   (D) homogeneous mixture
3. Which element is paired with the wrong symbol?
   (A) sulfur, S
   (B) potassium, P
   (C) nitrogen, N
   (D) calcium, Ca
4. Which of these properties could not be used to distinguish between table salt and table sugar?
   (A) boiling point
   (B) melting point
   (C) density
   (D) color
5. The state of matter characterized by a definite volume and an indefinite shape is a
   (A) solid. (C) mixture.
   (B) liquid. (D) gas.

The lettered choices below refer to Questions 6–9. A lettered choice may be used once, more than once, or not at all.

(A) compound
(B) heterogeneous mixture
(C) element
(D) homogeneous mixture



Which description correctly identifies each of the following materials?

6. air
7. carbon monoxide
8. zinc
9. mushroom pizza

Tips for Success

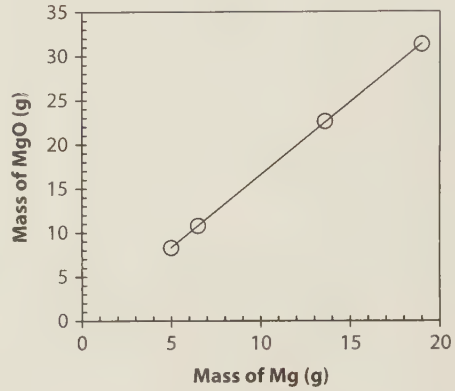
Using Models To answer some test questions, you will be asked to use visual models. At first the models may look very similar. Decide which information will help you answer the question. The number of particles, their colors, or their shapes may or may not be important.

Use the atomic windows to answer Question 10.

10. The species in window A react. Use the law of conservation of mass to determine which window best represents the reaction products.

Use the data table to answer Questions 11–14.

Mass of magnesium (g)	Mass of oxygen (g)	Mass of magnesium oxide (g)
5.0	3.3	8.3
6.5	(a)	10.8
13.6	9.0	(b)
(c)	12.5	31.5



11. Magnesium metal burns vigorously in oxygen to produce the compound magnesium oxide. Use the law of conservation of mass to identify the masses labeled (a), (b), and (c) in the table.
12. Use the data in the completed table to construct a graph with mass of magnesium on the *x*-axis and mass of magnesium oxide on the *y*-axis.
13. How many grams of magnesium oxide form when 8.0 g of magnesium are burned?
14. How many grams of magnesium and oxygen react to form 20.0 g of magnesium oxide?

If You Have Trouble With . . .

- aluminum can
- calculator
- small-scale pipet
- a pre- and post-1982 penny
- 8-well strip
- plastic cup

For the Teacher

Class Activity p 64
- a small object, such as a lead fishing weight
- triple-beam balance

Class Activity p 67
- almanacs or Internet access

Class Activity p 68
- scientific literature
- index cards

Class Activity p 76
- sets of Erlenmeyer flasks
- buret
- graduated cylinder beaker
- volumetric flask
- water
- food coloring

Class Activity p 77
- balance with a precision of at least 0.01 g
- sets of 10 pennies each separated according to minting dates between 1970 and the present (Be sure that sets include pre- and post-1982 minting dates.)

Class Activity p 81
- 3 or 4 different-sized cubes of a material such as wood, metal, or marble
- metric ruler
- balance

Class Activity p 85
- recipe
- lists of equivalents and conversions among the following measurements: teaspoon, tablespoon, 1/4 cup, 1/2 cup, and 1 cup

Class Activity p 89
- media guides containing vital statistics, such as heights and weights, of sports players

Online Teacher's Edition
Chemical Reactions

CHAPTER 3

What's Online

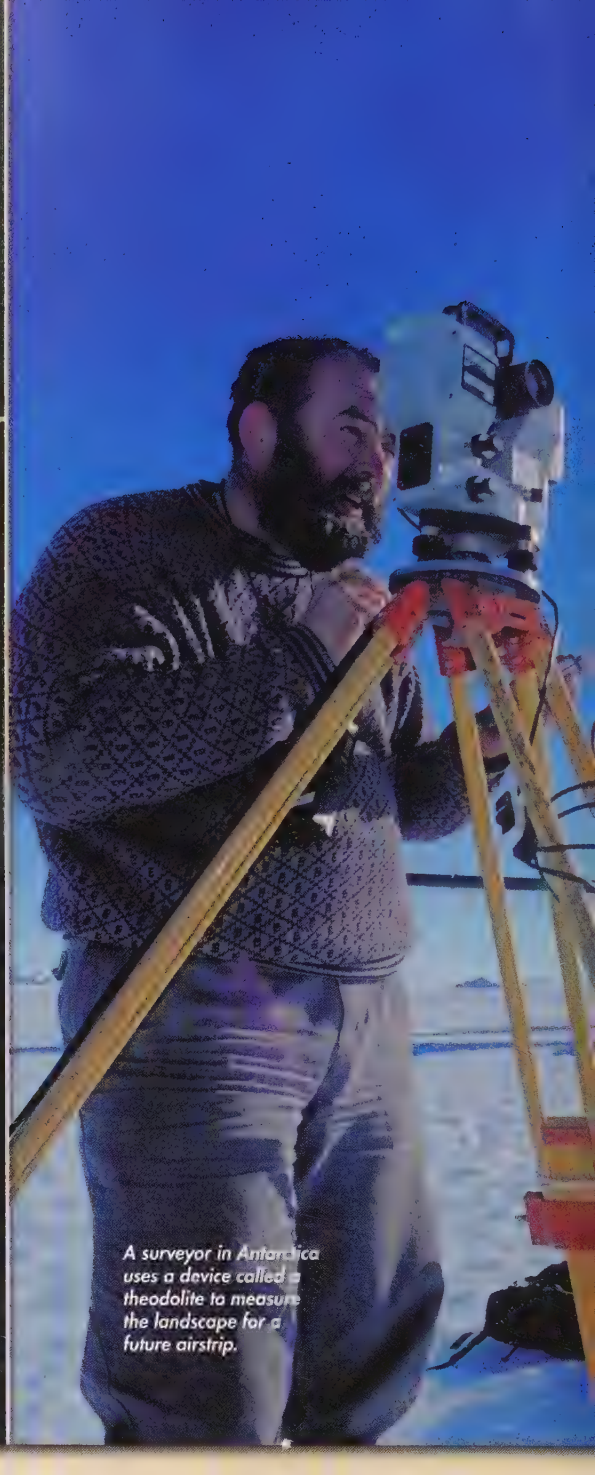
Students access guided, step-by-step tutorials for solving various measurement and conversion problems.

Students can practice key problem-solving skills in an online problem set.

Identify the students who struggle with math by assigning an online math skills diagnostic test. These students can then improve and practice math skills using the MathXL tutorial system.

Students go on an animated virtual lab tour in which density is studied in a simulated laboratory environment.

Student watch animations of a selected figures from the chapter followed by questions to check for understanding.



Watch an overview of a key chapter concept using real-world contexts and concrete examples and analogies. Each activity includes an interactive animation followed by analysis questions.

3 Scientific Measurement

INSIDE:

- **3.1** Using and Expressing Measurements
- **3.2** Units of Measurement
- **3.3** Solving Conversion Problems

PearsonChem.com

A surveyor in Antarctica uses a device called a theodolite to measure the landscape for a future airstrip.

60

IN ACADEMIC STANDARDS for SCIENCE

Nature of Science

- Clearly communicate their ideas and results of investigations verbally and in written form using tables, graphs, diagrams, and photographs.
- Apply standard techniques in laboratory investigations to measure physical quantities in appropriate units and convert known quantities to other units as necessary.

Standard 1: Properties and States of Matter

C.1.7 Define density and distinguish between materials based on densities. Perform calculations involving density.

Focus on ELL

1 CONTENT AND LANGUAGE Read the title of the chapter aloud to the class. List reasons why the word *scientific* is in front of the word *measurement*. Discuss what it means if a measurement is *not* scientific. Have students document the discussion with a KWL chart.

BEGINNING: LOW/HIGH Have students identify tools used to measure distance, mass, volume, and time, and order the tools based on their accuracy for small measurements.

INTERMEDIATE: LOW/HIGH Have students relate the measures provided with various tools to a familiar object, such as: the mass of a paperclip is about one gram.

ADVANCED: LOW/HIGH Have students practice identifying measurements as a length, a mass, a time, a temperature, or a volume.

BIG IDEA

QUANTIFYING MATTER

Essential Questions:

1. *How do scientists express the degree of uncertainty in their measurements?*
2. *How is dimensional analysis used to solve problems?*

CHEMYSTERY

Just Give Me a Sign

While traveling in a foreign country, you happen to get lost, as many tourists do. But then you spot these signs along the road. If you know the distance to your destination, you can find your way. However, in the signs shown here, the distances are listed as numbers with no units attached. For example, is Preston 8 kilometers away or 8 miles away? Is there any way to know for sure?

▶ Connect to the BIG IDEA As you read the chapter, try to familiarize yourself with common metric units used in science.

INDIANA'S ACADEMIC STANDARDS FOR SCIENCE

Properties and States of Matter C.1.7. See lessons for details.

Introduce the Chapter

IDENTIFYING PRECONCEPTIONS Students may think that measurements are either correct or incorrect. Use the activity to help them realize that measurements can be correct but have degrees of uncertainty.

Activity Divide the class into groups of two or three students, and provide each group with a meter stick and a metric ruler. Have different groups measure and record the length of a wall to the nearest meter, decimeter, centimeter, or millimeter. Afterwards, have groups compare their measurements. **Ask** Were the measurements for each type of unit the same? *(Answers will vary.)* **Ask** Which units do you think gave measurements closest to the actual length of the wall? *(millimeters)*

UbD

Understanding by Design

Students are building toward understanding how to use scientific measurement as a method of quantifying matter.

PERFORMANCE GOALS At the end of Chapter 3, students will be able to answer the essential questions by applying their knowledge of scientific measurement. Students will also be able to convert between common units of measurement and solve problems involving density.

ESSENTIAL QUESTIONS Read the essential questions aloud. **Ask** When you make a measurement, what are some possible sources of uncertainty? *(Sample answers: You might make a mistake when reading the measurement. The instrument you use might have increments so large that you are unable to obtain an accurate measurement.)* **Ask** What do the terms "dimension" and "analysis" mean? Based on this, what do you think "dimensional analysis" is? *("Dimension" is a unit of measurement, such as meter or liter. "Analysis" is trying to explain something by examining its parts. "Dimensional analysis" is trying to explain something by using its units.)*

BIG IDEA Use the photo of the surveyor to help students connect to the concepts they will learn in this chapter. Activate prior knowledge by asking students how they decide which units to use when making a measurement. Explain that the surveyor in the photo is using the theodolite to make very accurate measurements of angles. **Ask** Why is it important for his measurements to be so accurate? *(Sample answer: The airstrip needs to be located on a flat surface for safety.)* **Ask** What are some sources of uncertainty in his measurements? *(Sample answers: He could read the instrument markings incorrectly. The instrument may not have very small increments.)*

CHEMYSTERY Have students read over the CHEMystery. Connect the CHEMystery to the Big Idea of Quantifying Matter by engaging students in a discussion of different units they might use for different types of measurements. Point out that some descriptions of distances are not quantified. Examples include *far, close, and nearby*. When descriptions are quantified, a unit is needed to avoid ambiguity. Have students suggest ways that they might know for sure whether the distances on the sign are in kilometers or miles. As a hint, have them try to draw a map showing the locations of the cities relative to each other.

LESSON 3.1

Key Objectives

- **3.1.1 WRITE** numbers in scientific notation.
- **3.1.2 EVALUATE** accuracy and precision.
- **3.1.3 EXPLAIN** why measurements must be reported to the correct number of significant figures.

Additional Resources

- Reading and Study Workbook, Lesson 3.1

Core Teaching Resources, Lesson 3.1 Review

PearsonChem.com

Engage

CHEMISTRY & YOU Have students study the photograph and read the text that opens the section. **Ask** How do you think scientists ensure measurements are accurate and precise? *(Acceptable answers include that scientists make multiple measurements by using the most precise equipment available. They use samples with known values to check the reliability of the equipment.)*

Activate Prior Knowledge

Discuss the various everyday activities that involve measuring, as well as the tools used to make those measurements. Ask a volunteer to be measured for height. Hand out a tape measure, a yardstick, and a metric ruler to three students. Have each of these students measure the height of the volunteer with their tool and state aloud their measures. **Ask** Which measurement appears to be the most accurate? Why? *(The tool that seems to be the most appropriate for measuring height is probably the most accurate in this case.)*

IN ACADEMIC STANDARDS for SCIENCE

- Develop explanations based on reproducible data and observations gathered during laboratory investigations.

3.1 Using and Expressing Measurements

CHEMISTRY & YOU

Q: *How do you measure a photo finish?* You probably know that a 100-meter dash is timed in seconds. But if it's a close finish, measuring each runner's time to the nearest second will not tell you who won. That's why sprint times are often measured to the nearest hundredth of a second (0.01 s). Chemistry also requires making accurate and often very small measurements.

Key Questions

- ***How do you write numbers in scientific notation?***
- ***How do you evaluate accuracy and precision?***
- ***Why must measurements be reported to the correct number of significant figures?***

Vocabulary

- measurement
- scientific notation
- accuracy • precision
- accepted value
- experimental value
- error • percent error
- significant figures

Figure 3.1 Just a Hair
A hair's width expressed in meters is a very small measurement.

$0.00007\ \text{m} = 7 \times 10^{-5}\ \text{m}$

Decimal point moves 5 places to the right. Exponent is −5

Scientific Notation

How do you write numbers in scientific notation?

Everyone makes and uses measurements. A **measurement** is a quantity that has both a number and a unit. Your height (66 inches), your age (15 years), and your body temperature (37°C) are examples of measurements.

Measurements are fundamental to the experimental sciences. For that reason, it is important to be able to make measurements and to decide whether a measurement is correct. In chemistry, you will often encounter very large or very small numbers. A single gram of hydrogen, for example, contains approximately 602,000,000,000,000,000,000,000 hydrogen atoms. The mass of an atom of gold is 0.000 000 000 000 000 000 000 327 gram. Writing and using such large and small numbers is cumbersome. You can work more easily with these numbers by writing them in scientific notation.

In **scientific notation,** a given number is written as the product of two numbers: a coefficient and 10 raised to a power. For example, the number 602,000,000,000,000,000,000,000 can be written in scientific notation as 6.02×10^{23}. The coefficient in this number is 6.02. The power of 10, or exponent, is 23. **In scientific notation, the coefficient is always a number greater than or equal to one and less than ten. The exponent is an integer.** A positive exponent indicates how many times the coefficient must be multiplied by 10. A negative exponent indicates how many times the coefficient must be divided by 10. Figure 3.1 shows a magnified view of a human hair, which has a diameter of about 0.00007 m, or 7×10^{-5} m.

When writing numbers greater than ten in scientific notation, the exponent is positive and equals the number of places that the original decimal point has been moved to the left.

$6{,}300{,}000. = 6.3 \times 10^{6}$ $\qquad$ $94{,}700. = 9.47 \times 10^{4}$

Numbers less than one have a negative exponent when written in scientific notation. The value of the exponent equals the number of places the decimal has been moved to the right.

$0.000\,008 = 8 \times 10^{-6}$ $\qquad$ $0.00736 = 7.36 \times 10^{-3}$

Focus on ELL

1 CONTENT AND LANGUAGE Review the abbreviations used in the lesson. Supply the class with a listing for each abbreviation and its meaning. Read aloud each abbreviation and have students repeat.

2 FRONTLOAD THE LESSON Put together a display of common and uncommon measuring tools that students can examine prior to the lesson. Ask students to group the tools on the basis of the type of measurement for which they believe the tools are used: distance, time, volume, and so forth. Have students predict which tools in each group are the most and least accurate. Revisit students' predictions after completing the lesson.

3 COMPREHENSIBLE INPUT When discussing Figure 3.2, assist students in completing the associated analogy by allowing them to test their answers with an unzeroed balance.

Multiplication and Division To multiply numbers written in scientific notation, multiply the coefficients and add the exponents.

$$(3 \times 10^4) \times (2 \times 10^2) = (3 \times 2) \times 10^{4+2} = 6 \times 10^6$$

$$(2.1 \times 10^3) \times (4.0 \times 10^{-7}) = (2.1 \times 4.0) \times 10^{3+(-7)} = 8.4 \times 10^{-4}$$

To divide numbers written in scientific notation, divide the coefficients and subtract the exponent in the denominator from the exponent in the numerator.

$$\frac{3.0 \times 10^5}{6.0 \times 10^2} = \left(\frac{3.0}{6.0}\right) \times 10^{5-2} = 0.5 \times 10^3 = 5.0 \times 10^2$$

Addition and Subtraction If you want to add or subtract numbers expressed in scientific notation and you are not using a calculator, then the exponents must be the same. In other words, the decimal points must be aligned before you add or subtract the numbers. For example, when adding 5.4×10^3 and 8.0×10^2, first rewrite the second number so that the exponent is a 3. Then add the numbers.

$$\begin{aligned}(5.4 \times 10^3) + (8.0 \times 10^2) &= (5.4 \times 10^3) + (0.80 \times 10^3) \\ &= (5.4 + 0.80) \times 10^3 \\ &= 6.2 \times 10^3\end{aligned}$$

Sample Problem 3.1

Using Scientific Notation

Solve each problem and express the answer in scientific notation.

a. $(8.0 \times 10^{-2}) \times (7.0 \times 10^{-5})$ **b.** $(7.1 \times 10^{-2}) + (5 \times 10^{-3})$

1 Analyze **Identify the relevant concepts.** To multiply numbers in scientific notation, multiply the coefficients and add the exponents. To add numbers in scientific notation, the exponents must match. If they do not, then adjust the notation of one of the numbers.

2 Solve **Apply the concepts to this problem.**

Multiply the coefficients and add the exponents.

a. $(8.0 \times 10^{-2}) \times (7.0 \times 10^{-5}) = (8.0 \times 7.0) \times 10^{-2+(-5)}$
$= 56 \times 10^{-7}$
$= 5.6 \times 10^{-6}$

Rewrite one of the numbers so that the exponents match. Then add the coefficients.

b. $(7.1 \times 10^{-2}) + (5 \times 10^{-3}) = (7.1 \times 10^{-2}) + (0.5 \times 10^{-2})$
$= (7.1 + 0.5) \times 10^{-2}$
$= 7.6 \times 10^{-2}$

1. Solve each problem and express the answer in scientific notation.
a. $(6.6 \times 10^{-8}) + (5.0 \times 10^{-9})$
b. $(9.4 \times 10^{-2}) - (2.1 \times 10^{-2})$

2. Calculate the following and write your answer in scientific notation:
$$\frac{6.6 \times 10^6}{(8.8 \times 10^{-2}) \times (2.5 \times 10^3)}$$

Foundations for Math

CALCULATIONS INVOLVING SCIENTIFIC NOTATION Tell students that solving problems in chemistry often involves numbers written in scientific notation. Explain that when multiplying or dividing numbers written in scientific notation, the exponents do not have to be the same. However, when adding or subtracting without a calculator, the exponents must be the same. Point out that another way to combine numbers written in scientific notation is to write both numbers in standard form first, perform the operation, and then convert the resulting answer back to scientific notation.

In **Sample Problem 3.1b**, each number can be written in standard form first. Some students may find this easier than changing the exponent for one of the numbers to make them match.

$$7.1 \times 10^{-2} = 0.071$$

$$5 \times 10^{-3} = 0.005$$

Now add: $0.071 + 0.005 = 0.076 = 7.6 \times 10^{-2}$

Foundations for Reading

BUILD VOCABULARY Have students write definitions of the words *accurate* and *precise* in their own words. As they read the text, have students compare the definitions with those of *accuracy* and *precision* given in the text.

READING STRATEGY After reading each section, create a bulleted list summarizing the meaning of the key words or summarizing the rules to follow. Have students compare their lists with others. Break the class into small groups and have each group consolidate their individual efforts into a group summary.

Explain

Scientific Notation

USE VISUALS Have students study Figure 3.1.
Ask How is the exponent of a number expressed in scientific notation related to the number of places the decimal point is moved to the right in a number smaller than 1? *(They are equal.)*

Sample Practice Problem

Calculate the following and express your answers in scientific notation.

1. $(3.0 \times 10^{-3}) \times (2.5 \times 10^{-4}) = ?$
(7.5×10^{-7})
2. $(4.2 \times 10^{-3}) + (7.0 \times 10^{-4}) = ?$
(4.9×10^{-3})

Answers

1. **a.** 7.1×10^{-8} **b.** 7.3×10^{-2}
2. 3.0×10^4

LESSON 3.1

Explain

Accuracy, Precision, and Error

USE VISUALS Have students inspect Figure 3.2. **Ask** If one dart in Figure 3.2c were closer to the bull's-eye, what would happen to the accuracy? *(The accuracy would increase.)* **Ask** What would happen to the precision? *(The precision would increase.)* **Ask** What is the operational definition of error implied by this figure? *(The error is the distance between the dart and the bull's-eye.)*

Explore

Class Activity

PURPOSE Students will explore the concepts of precision and accuracy.

MATERIALS a small object (such as a lead fishing weight), triple-beam balance

PROCEDURE Place the object and a triple-beam balance in a designated area. Set a deadline by which each student will have measured the mass of the object. After everyone has had an opportunity, have students compile a summary of all the measurements. Illustrate precision by having the students find the average and compare their measurement to it.

EXPECTED OUTCOME Measured values should be similar, but not necessarily identical, for all students.

USE ANALOGIES Guide students to think of other analogies that may be useful in explaining precision vs. accuracy, such as casting a fishing line, pitching horseshoes, or marching in a precision marching band.

Accuracy, Precision, and Error

How do you evaluate accuracy and precision?

Your success in the chemistry lab and in many of your daily activities depends on your ability to make reliable measurements. Ideally, measurements should be both correct and reproducible.

Accuracy and Precision Correctness and reproducibility relate to the concepts of accuracy and precision, two words that mean the same thing to many people. In chemistry, however, their meanings are quite different. **Accuracy** is a measure of how close a measurement comes to the actual or true value of whatever is measured. **Precision** is a measure of how close a series of measurements are to one another, irrespective of the actual value. **To evaluate the accuracy of a measurement, the measured value must be compared to the correct value. To evaluate the precision of a measurement, you must compare the values of two or more repeated measurements.**

Darts on a dartboard illustrate accuracy and precision in measurement. Let the bull's-eye of the dartboard in Figure 3.2 represent the true, or correct, value of what you are measuring. The closeness of a dart to the bull's-eye corresponds to the degree of accuracy. The closer it comes to the bull's-eye, the more accurately the dart was thrown. The closeness of several darts to one another corresponds to the degree of precision. The closer together the darts are, the greater the precision and the reproducibility.

Figure 3.2 Accuracy vs. Precision
The distribution of darts illustrates the difference between accuracy and precision.
Use Analogies ***Which outcome describes a scenario in which you properly measure an object's mass three times using a balance that has not been zeroed?***

Good Accuracy, Good Precision
Closeness to the bull's-eye indicates a high degree of accuracy. The closeness of the darts to one another indicates high precision.

Poor Accuracy, Good Precision
Precision is high because of the closeness of grouping—thus, the high level of reproducibility. But the results are inaccurate.

Poor Accuracy, Poor Precision
The darts land far from one another and from the bull's-eye. The results are both inaccurate and imprecise.

Determining Error Suppose you use a thermometer to measure the boiling point of pure water at standard pressure. The thermometer reads 99.1°C. You probably know that the true or accepted value of the boiling point of pure water at these conditions is actually 100.0°C.

Professional Development Note

Striving for Scientific Accuracy

The French chemist Antoine Lavoisier worked hard to establish the importance of accurate measurement in scientific inquiry. Lavoisier devised an experiment to test the Greek scientists' idea that when water was heated, it could turn into earth. For 100 days, Lavoisier boiled water in a glass flask constructed to allow steam to condense without escaping. He weighed the water and the flask separately before and after boiling. He found that the mass of the water had not changed. The flask, however, lost a small mass equal to the sediment he found in the bottom of it. Lavoisier proved that the sediment was not earth, but part of the flask etched away by the boiling water.

There is a difference between the **accepted value,** which is the correct value for the measurement based on reliable references, and the **experimental value,** the value measured in the lab. The difference between the experimental value and the accepted value is called the **error.**

$$\text{Error} = \text{experimental value} - \text{accepted value}$$

Error can be positive or negative, depending on whether the experimental value is greater than or less than the accepted value. For the boiling-point measurement, the error is 99.1°C − 100.0°C, or −0.9°C.

The magnitude of the error shows the amount by which the experimental value differs from the accepted value. Often, it is useful to calculate the relative error, or percent error. The **percent error** of a measurement is the absolute value of the error divided by the accepted value, multiplied by 100%.

$$\text{Percent error} = \frac{|\text{error}|}{\text{accepted value}} \times 100\%$$

READING SUPPORT

Build Reading Skills: ***Inference***
As you read, try to identify some of the factors that cause experimental error. ***What factors might result in inaccurate measurements? What factors might result in imprecise measurements?***

SampleProblem 3.2

Calculating Percent Error

The boiling point of pure water is measured to be 99.1°C. Calculate the percent error.

1 Analyze **List the knowns and unknown.**
The accepted value for the boiling point of pure water is 100°C. Use the equations for error and percent error to solve the problem.

KNOWNS	UNKNOWN
Experimental value = 99.1°C	Percent error = ?
Accepted value = 100.0°C	

2 Calculate **Solve for the unknown.**

Start with the equation for percent error.

$$\text{Percent error} = \frac{|\text{error}|}{\text{accepted value}} \times 100\%$$

Substitute the equation for error, and then plug in the known values.

$$\text{Percent error} = \frac{|\text{experimental value} - \text{accepted value}|}{\text{accepted value}} \times 100\%$$

$$= \frac{|99.1°C - 100.0°C|}{100.0°C} \times 100\%$$

$$= \frac{0.9°C}{100.0°C} \times 100\% = 0.9\%$$

3 Evaluate **Does the result make sense?** The experimental value was off by about 1°C, or $\frac{1}{100}$ of the accepted value (100°C). The answer makes sense.

3. A student measures the depth of a swimming pool to be 2.04 meters at its deepest end. The accepted value is 2.00 m. What is the student's percent error?

Think about it: Using the absolute value of the error means that percent error will always be a positive value.

Foundations for Math

ABSOLUTE VALUE Remind students that the absolute value of a number is its distance from zero on a number line and is always written as a positive number. So, |4.2| = 4.2 and |–4.2| = 4.2.

In **Sample Problem 3.2**, the numerator in the fraction of the formula is the absolute value of the error. Regardless of whether the experimental value or the accepted value is larger, the percent error will always be a positive value.

Explain

START A CONVERSATION Review the concept of absolute value. **Ask** What is the meaning of a *positive* error? *(The measured value is greater than the accepted value.)* **Ask** What is the meaning of a *negative* error? *(The measured value is less than the accepted value.)* Explain that the absolute value of the error is a positive value that describes the difference between the measured value and the accepted value, but not which is greater.

Sample Practice Problem

Diamonds and other gemstones are measured in carats. The accepted value for the weight of a carat is 0.2 gram. A jeweler measured the weight of a carat of opals to be 0.192 gram. What is the percent error? (4%)

Answers

READING SUPPORT Inaccurate measurements may be due to uncalibrated instruments or incorrect experimental procedure; imprecise measurements may be due to poor instrument operation, variable experimental conditions, or errors in reading output values.

FIGURE 3.2 poor accuracy, good precision

3. 2%

Explain

Significant Figures

START A CONVERSATION Point out that the concept of significant figures applies only to measured quantities. If students ask why an estimated digit is considered significant, tell them a significant figure is one that is known to be reasonably reliable. A careful estimate fits this definition.

USE VISUALS Direct students' attention to Figure 3.3. Point out that when calibration marks on an instrument are spaced very close together (e.g., on certain thermometers and graduated cylinders), it is sometimes more practical to estimate a measurement to the nearest half of the smallest calibrated increment, rather than to the nearest tenth.

CRITICAL THINKING As students inspect Figure 3.4, model the use of the top meter stick by pointing out that one can be certain that the width of the door is between 0 and 1 m, and one can say that the actual width is closer to 1 m. Thus, one can estimate the width as 0.8 m. Similarly, using the middle meter stick, one can say with certainty that the width is between 70 and 80 cm. Because the width is very close to 80 cm, one should estimate the width as 77 cm or 0.77 m. Have students study the bottom meter stick and use similar reasoning to describe the measurement and estimation process. **Ask** If the bottom meter stick were divided into 0.001 m intervals, as are most meter sticks, what would be the estimated width of the door in meters? *(Acceptable answers range from 0.7715 to 0.7724 m.)* In millimeters? *(771.5 to 772.4)*

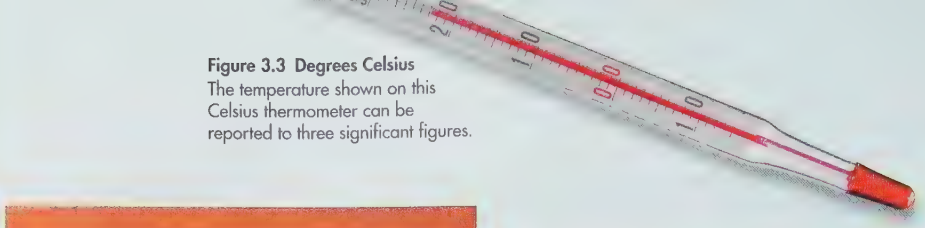


Figure 3.3 Degrees Celsius
The temperature shown on this Celsius thermometer can be reported to three significant figures.

Significant Figures

Why must measurements be reported to the correct number of significant figures?

Look at the reading of the thermometer shown in Figure 3.3. If you use a liquid-filled thermometer that is calibrated in 1°C intervals, you can easily read the temperature to the nearest degree. With the same thermometer, however, you can also estimate the temperature to about the nearest tenth of a degree by noting the closeness of the liquid inside to the calibrations. Looking at Figure 3.3, suppose you estimate that the temperature lies between 22°C and 23°C, at 22.9°C. This estimated number has three digits. The first two digits (2 and 2) are known with certainty. But the rightmost digit (9) has been estimated and involves some uncertainty. These reported digits all convey useful information, however, and are called significant figures. The **significant figures** in a measurement include all of the digits that are known, plus a last digit that is estimated. **Measurements must always be reported to the correct number of significant figures because calculated answers often depend on the number of significant figures in the values used in the calculation.**

Instruments differ in the number of significant figures that can be obtained from their use and thus in the precision of measurements. The three meter sticks in Figure 3.4 can be used to make successively more precise measurements.

More on precision in measurements *online.*

Figure 3.4 Increasing Precision
Three differently calibrated meter sticks are used to measure a door's width. A meter stick calibrated in 0.1-m (1 dm) intervals is more precise than one calibrated in a 1-m interval but less precise than one calibrated in 0.01-m (1 cm) intervals. **Measure** ***How many significant figures are reported in each measurement?***

UbD Check for Understanding

The Essential Question **How do scientists express their uncertainty in measurement?**

Assess students' understanding of the Essential Question by asking students to complete the following statement:

A measured value's uncertainty is expressed by its _____ digit. *(final; last; rightmost)*

ADJUST INSTRUCTION If students are having difficulty answering, refer them to Figure 3.3. Point out that the rightmost digit in each measurement is an estimated value. The fact that the rightmost digit is estimated gives the digit its uncertainty.

Determining Significant Figures in Measurements To determine whether a digit in a measured value is significant, you need to apply the following rules.

1. Every nonzero digit in a reported measurement is assumed to be significant.

24.7 meters
0.743 meter
714 meters

Each of these measurements has three significant figures.

2. Zeros appearing between nonzero digits are significant.

7003 meters
40.79 meters
1.503 meters

Each of these measurements has four significant figures.

3. Leftmost zeros appearing in front of nonzero digits are not significant. They act as placeholders. By writing the measurements in scientific notation, you can eliminate such placeholding zeros.

0.0071 meter = 7.1×10^{-3} meter
0.42 meter = 4.2×10^{-1} meter
0.000099 meter = 9.9×10^{-5} meter

Each of these measurements has only two significant figures.

4. Zeros at the end of a number and to the right of a decimal point are always significant.

43.00 meters
1.010 meters
9.000 meters

Each of these measurements has four significant figures.

5. Zeros at the rightmost end of a measurement that lie to the left of an understood decimal point are not significant if they serve as placeholders to show the magnitude of the number.

300 meters (one significant figure)
7000 meters (one significant figure)
27,210 meters (four significant figures)

The zeros in these measurements are not significant.

If such zeros were known measured values, however, then they would be significant. Writing the value in scientific notation makes it clear that these zeros are significant.

300 meters = 3.00×10^2 meters (three significant figures)

The zeros in this measurement are significant.

6. There are two situations in which numbers have an unlimited number of significant figures. The first involves counting. A number that is counted is exact.

23 people in your classroom

This measurement is a counted value, so it has an unlimited number of significant figures.

The second situation involves exactly defined quantities such as those found within a system of measurement.

60 min = 1 hr
100 cm = 1 m

Each of these numbers has an unlimited number of significant figures.

Differentiated Instruction

LPR LESS PROFICIENT READERS Have students write in their own words the rules for determining the number of significant digits. Help them if necessary. Direct them to make several measurements, and then use their rules to correctly determine the correct number of significant digits in the measurements.

L1 STRUGGLING STUDENTS Create one set of flash cards for each rule. Write three numerical values on each card—two values that follow the rule and one that does not follow the rule. Have students identify the two values that follow the rule and explain why the third values does not.

ELL ADVANCED LEARNERS Have students determine how a measurement, such as area or volume, can be precise without being accurate.

Explore

Class Activity

PURPOSE Students will explore how similar measurements from different eras may vary in precision.

MATERIALS Almanacs or Internet access

PROCEDURE Have students look up the winning times for the men's and women's 100-meter dashes at the 1948 and 2008 Olympic Games. **Ask** Why do the more recently recorded race times contain more digits to the right of the decimal? *(The technology used for timekeeping improved to allow for more precise measurements.)*

EXPECTED OUTCOME Students should find that the race times from 1948 were recorded to the nearest tenth of a second. The race times from 2008 were recorded to the nearest hundredth of a second.

Answers

FIGURE 3.4 0.8 m, one significant figure; 0.77 m, two significant figures; 0.772 m, three significant figures

Explore

Class Activity

PURPOSE Students will practice applying the rules governing the significance of zeros in measurements.

MATERIALS textbook and scientific literature, index cards

PROCEDURE Have students search their textbooks and other sources for length, mass, volume, or temperature measurements that contain zeros. Have them include some examples written in scientific notation. Ask them to write each measurement on the front of an index card; on the back of each card, have them write (1) all the rules governing the significance of zeros that apply to the measurement, and (2) the number of significant figures in the measurement. Have pairs of students exchange index cards and agree on the appropriateness of the rules and the answers.

EXPECTED OUTCOME Students should be able to apply correctly rules 2–5 listed on page 69.

Explain

DRAW A CONCLUSION Explain that due to rounding, there will often be discrepancies between actual values and calculated values derived from measurements. Ask students to draw a conclusion about whether following the rules for significant figures introduces error in calculated values. *(Although rounding errors are generally small, they should be acknowledged when performing calculations.)*

CHEMISTRY & YOU The time of 9.98 seconds has three significant figures, and the time of 10.05 seconds has four significant figures. Both times have the same accuracy because they are measured to the nearest 0.01 second.

Sample Practice Problem

How many significant figures does the number 103,400 have? (*4*)

Sample Problem 3.3

Counting Significant Figures in Measurements

How many significant figures are in each measurement?

a. 123 m
b. 40,506 mm
c. 9.8000×10^4 m
d. 22 meter sticks
e. 0.070 80 m
f. 98,000 m

Make sure you understand the rules for counting significant figures (on the previous page) before you begin, okay?

1 Analyze **Identify the relevant concepts.** The location of each zero in the measurement and the location of the decimal point determine which of the rules apply for determining significant figures. These locations are known by inspecting each measurement value.

2 Solve **Apply the concepts to this problem.**

Apply the rules for determining significant figures. All nonzero digits are significant (rule 1). Use rules 2 through 5 to determine if the zeros are significant.

a. three (rule 1)
b. five (rule 2)
c. five (rule 4)
d. unlimited (rule 6)
e. four (rules 2, 3, 4)
f. two (rule 5)

4. Count the significant figures in each measured length.
a. 0.057 30 meter
b. 8765 meters
c. 0.000 73 meter
d. 40.007 meters

5. How many significant figures are in each measurement?
a. 143 grams
b. 0.074 meter
c. 8.750×10^{-2} gram
d. 1.072 meters

CHEMISTRY & YOU

Q: *Suppose that the winner of a 100-meter dash finishes the race in 9.98 seconds. The runner in second place has a time of 10.05 seconds. How many significant figures are in each measurement? Is one measurement more accurate than the other? Explain your answer.*

Significant Figures in Calculations Suppose you use a calculator to find the area of a floor that measures 7.7 meters by 5.4 meters. The calculator would give an answer of 41.58 square meters. However, each of the measurements used in the calculation is expressed to only two significant figures. As a result, the answer must also be reported to two significant figures (42 m^2). In general, a calculated answer cannot be more precise than the least precise measurement from which it was calculated. The calculated value must be rounded to make it consistent with the measurements from which it was calculated.

Rounding To round a number, you must first decide how many significant figures the answer should have. This decision depends on the given measurements and on the mathematical process used to arrive at the answer. Once you know the number of significant figures your answer should have, round to that many digits, counting from the left. If the digit immediately to the right of the last significant digit is less than 5, it is simply dropped and the value of the last significant digit stays the same. If the digit in question is 5 or greater, the value of the digit in the last significant place is increased by 1.

Foundations for Math

ZEROS IN SIGNIFICANT FIGURES Remind students that a number may contain both significant and nonsignificant zeros. In this situation, more than one rule must be applied to determine which zeros are significant and which zeros are not significant.

In **Sample Problem 3.3e,** the number 0.07080 contains both significant and nonsignificant zeros. Rewriting this number in scientific notation makes it easier to determine which zeros are significant figures, by removing the nonsignificant zeros from immediate view:

$$0.07080 = 7.080 \times 10^{-2}$$

Now it is obvious that the zeros to the left of the 7 act as placeholders and are not significant, while the remaining two zeros *are* significant because of their location.

Sample Problem 3.4

Rounding Measurements

Round off each measurement to the number of significant figures shown in parentheses. Write the answers in scientific notation.

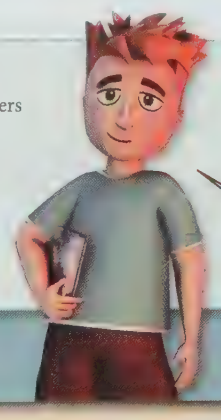
a. 314.721 meters (four)
b. 0.001 775 meter (two)
c. 8792 meters (two)

1 Analyze **Identify the relevant concepts.** Using the rules for determining significant figures, round the number in each measurement. Then apply the rules for expressing numbers in scientific notation.

2 Solve **Apply the concepts to this problem.**

Starting from the left, count the first four digits that are significant. The arrow points to the digit immediately following the last significant digit.

a. 314.721 meters
↑
2 is less than 5, so you do not round up.
314.7 meters = 3.147×10^2 meters



Starting from the left, count the first two digits that are significant. The arrow points to the digit immediately following the second significant digit.

b. 0.001 775 meters
↑
7 is greater than 5, so round up.
0.0018 meter = 1.8×10^{-3} meter

Starting from the left, count the first two digits that are significant. The arrow points to the digit immediately following the second significant digit.

c. 8792 meters
↑
9 is greater than 5, so round up.
8800 meters = 8.8×10^3 meters

6. Round each measurement to three significant figures. Write your answers in scientific notation.
a. 87.073 meters
b. 4.3621×10^8 meters
c. 0.01552 meter
d. 9009 meters
e. 1.7777×10^{-3} meter
f. 629.55 meters

7. Round each measurement in Problem 6 to one significant figure. Write each of your answers in scientific notation.

If you're already familiar with rounding numbers, you can skip to Sample Problems 3.5 and 3.6.

Foundations for Math

COMMON ERROR Stress to students that rounding to a given number of significant figures is not necessarily the same thing as rounding to that many decimal places. For example, if 7.376 is rounded to two significant figures, the result is 7.4. Students often confuse this process with rounding to two decimal places, in which case the result would be 7.38. This number has three significant figures, not two.

In **Sample Problem 3.4b,** none of the zeros are significant. Stress that the answer is not rounded to two decimal places. Rather, the number will be rounded to four decimal places because the second significant figure (7) is in the ten ten-thousandths place.

Explain

Significant Figures

SUMMARIZE As a class, summarize the rules for significant figures in a bulleted list or a fishbone map. Students should state the rules in their own words and provide an example for each rule.

Misconception Alert

Some students may think that because they use a calculator, that there results are shown with the proper number of significant figures. Explain that this is not the case, and even scientific calculators or graphing calculators do not round answers to the correct number of significant figures.

Sample Practice Problem

Round each measurement to two significant figures. Write your answer in scientific notation.

a. 94.592 grams *(9.5×10^1 g)*
b. 2.4332×10^3 grams *(2.4×10^3 g)*
c. 0.007438 grams *(7.4×10^{-3} g)*
d. 54,752 grams *(5.5×10^4 g)*
e. 6.0289×10^{-3} grams *6.0×10^{-3} g)*
f. 405.11 grams *(4.1×10^2 g)*

Answers

4. **a.** 4 **c.** 2
b. 4 **d.** 5
5. **a.** 3 **c.** 4
b. 2 **d.** 4
6. **a.** 8.71×10^1 m
b. 4.36×10^8 m
c. 1.55×10^{-2} m
d. 9.01×10^3 m
e. 1.78×10^{-3} m
f. 6.30×10^2 m
7. **a.** 9×10^1 m
b. 4×10^8 m
c. 2×10^{-2} m
d. 9×10^3 m
e. 2×10^{-3} m
f. 6×10^2 m

Explain

START A CONVERSATION The rules for rounding calculated numbers can be compared with the old adage, "A chain is only as strong as its weakest link." Explain that an answer cannot be more precise than the least precise value used to calculate the answer. **Ask** In addition and subtraction, what is the least precise value? *(The measurement with the fewest digits to the right of the decimal point.)* **Ask** In multiplication and division, what is the least precise value? *(The measurement with the fewest significant figures.)* If students wonder why addition and subtraction rules differ from multiplication and division rules, point out that in addition and subtraction of measurements, the measurements are of the same property, such as length or volume. However, in the multiplication and division of measurements, new quantities or properties are being described, such as speed (length ÷ time), area (length × length), or density (mass ÷ volume).

Misconception Alert

Students may argue that making one measurement of a dimension, such as length, is adequate. **Ask** What possible errors may occur when making only one length measurement? *(Acceptable answers include misreading the ruler or not holding the ruler parallel to the length of the object.)*

Sample Practice Problem

What is the total mass of three rock samples that have measured masses of 20.72 grams, 24.8 grams, and 17.35 grams? *(62.9 grams)*

Addition and Subtraction The answer to an addition or subtraction calculation should be rounded to the same number of decimal places (not digits) as the measurement with the least number of decimal places. Sample Problem 3.5 gives examples of rounding in addition and subtraction.

Multiplication and Division In calculations involving multiplication and division (such as those in Sample Problem 3.6), you need to round the answer to the same number of significant figures as the measurement with the least number of significant figures. The position of the decimal point has nothing to do with the rounding process when multiplying and dividing measurements. The position of the decimal point is important only in rounding the answers of addition or subtraction problems.

SampleProblem 3.5

Significant Figures in Addition and Subtraction

Perform the following addition and subtraction operations. Give each answer to the correct number of significant figures.

a. 12.52 meters + 349.0 meters + 8.24 meters

b. 74.626 meters − 28.34 meters

1 Analyze **Identify the relevant concepts.** Perform the specified math operation, and then round the answer to match the measurement with the least number of decimal places.

2 Solve **Apply the concepts to this problem.**

Align the decimal points and add the numbers.

```
a.   12.52  meters
     349.0  meters
+      8.24 meters
     369.76 meters
```

The second measurement (349.0 meters) has the least number of digits (one) to the right of the decimal point. So the answer must be rounded to one digit after the decimal point.

369.8 meters = 3.698×10^2 meters

Align the decimal points and subtract the numbers.

```
b.   74.626 meters
   − 28.34  meters
     46.286 meters
```

The second measurement (28.34 meters) has the least number of digits (two) to the right of the decimal point. So the answer must be rounded to two digits after the decimal point.

46.29 meters = 4.629×10^1 meters

8. Perform each operation. Express your answers to the correct number of significant figures.

a. 61.2 meters + 9.35 meters + 8.6 meters

b. 9.44 meters − 2.11 meters

c. 1.36 meters + 10.17 meters

d. 34.61 meters − 17.3 meters

9. Find the total mass of three diamonds that have masses of 14.2 grams, 8.73 grams, and 0.912 gram.

Foundations for Math

ADDITION AND SIGNIFICANT FIGURES Explain to students that when performing calculations that involve measurements with significant figures, the final result must be rounded to be consistent with the measurements. When adding and subtracting, if the measurements have different numbers of significant figures, the final result should be rounded to the same number of decimal places as the number with the least number of decimal places.

In **Sample Problem 3.5,** the first step should be to identify the measurement with the least number of decimal places. Encourage students to underline or circle this measurement. The result of the calculation should be rounded to the same number of decimal places (not digits) as this measurement.

Sample Problem 3.6

Significant Figures in Multiplication and Division

Perform the following operations. Give the answers to the correct number of significant figures.

a. 7.55 meters × 0.34 meter
b. 2.10 meters × 0.70 meter
c. 2.4526 meters^2 ÷ 8.4 meters
d. 0.365 meter^2 ÷ 0.0200 meter

1 Analyze **Identify the relevant concepts.** Perform the specified math operation, and then round the answer to match the measurement with the least number of significant figures.

2 Solve **Apply the concepts to this problem.**

The second measurement (0.34 meter) has the least number of significant figures (two). So the answer must be rounded to two significant figures.

a. 7.55 meters × 0.34 meter = 2.567 (meter)^2
= 2.6 meters^2

The second measurement (0.70 meter) has the least number of significant figures (two). So the answer must be rounded to two significant figures.

b. 2.10 meters × 0.70 meter = 1.47 (meter)^2
= 1.5 meters^2

The second measurement (8.4 meters) has the least number of significant figures (two). So the answer must be rounded to two significant figures.

c. 2.4526 meters^2 ÷ 8.4 meters = 0.291 976 meter
= 0.29 meter

Both measurements have three significant figures. So the answer must be rounded to three significant figures.

d. 0.365 meters^2 ÷ 0.0200 meter = 18.25 meters
= 18.3 meters

10. Solve each problem. Give your answers to the correct number of significant figures and in scientific notation.

a. 8.3 meters × 2.22 meters
b. 8432 meters^2 ÷ 12.5 meters
c. 35.2 seconds × $\frac{1 \text{ minute}}{60 \text{ seconds}}$

11. Calculate the volume of a warehouse that has measured dimensions of 22.4 meters by 11.3 meters by 5.2 meters. (Volume = $l \times w \times h$)

In Problem 11, the measurement with the fewest significant figures is 5.2 meters. What does this tell you?

Focus on ELL

4 LANGUAGE PRODUCTION Have students work in pairs to complete the lab. Make sure each pair has ELLs of varied language proficiencies, so that more proficient students can help less proficient ones. Have students work according to their proficiency level.

BEGINNING: LOW/HIGH Underline the action verbs in each step of the procedure. Work with a partner to follow each step.

INTERMEDIATE: LOW/HIGH Use a chart to keep track of the different measurements needed for the lab.

ADVANCED: LOW/HIGH With the help of a partner, answer #2 of the Analyze and Conclude section of the lab.

Explain

Sample Practice Problem

A small rectangular container has measured dimensions of 4.25 inches by 8.5 inches by 1.75 inches. What is the volume of the container? *(63 cubic inches)*

Evaluate

Informal Assessment

Write the following sets of measurements on the board.

(1) 70°C, 70°C, 80°C

(2) 77°C, 78°C, 78°C

(3) 80.25°C, 84.50°C, 86.00°C

Ask The temperature of a liquid under similar conditions was measured every ten minutes by three different students. Which student had the most precise measuring instrument? *(Set 3 is the most precise because the measurements have the greatest number of significant figures.)* **Ask** What would have to be known to determine which set is the most accurate? *(the accepted value of the liquid's boiling point)*

Reteach

Use Figure 3.4 to reteach the method of correctly recording the number of significant figures in a measurement. Then have students convert each measurement into scientific notation. *(8×10^{-1} m, 7.7×10^{-1} m, 7.72×10^{-1} m)*

Answers

8. **a.** 79.2 m **b.** 7.33 m **c.** 11.53 m **d.** 17.3 m
9. 23.8 g
10. **a.** 1.8×10^1 m^2
b. 6.75×10^2 m
c. 5.87×10^{-1} min
11. 1.3×10^3 m^3

Explore

QuickLab

OBJECTIVES After completing this activity, students will be able to measure length with accuracy and precision, apply rules for rounding answers calculated from measurements, and determine experimental error and express it as percent error.

SKILLS FOCUS Measuring, calculating

PREP TIME 5 minutes

CLASS TIME 15 minutes

MATERIALS 3 inch × 5 inch index cards, metric rulers

TEACHING TIPS Emphasize that students should use an interior, marked line, such as 10.0 cm, as the initial point, instead of the end of the ruler, which may be damaged.

EXPECTED OUTCOME Measured values should be similar, but not necessarily identical, for all students.

ANALYZE AND CONCLUDE

1. Four for length; three for width
2. See Expected Outcome.
3. Significant digits for rounded-off answers are area, 3, and perimeter, 4. Some students may not round to the proper number of digits.
4. Errors of ±0.03 cm are acceptable. Such errors yield percent errors of 0.2% for length and 0.4% for width.

FOR ENRICHMENT Have students devise methods of calculating the volume of one card. Point out that measuring the thickness of one card with a ruler would be very inaccurate. **Ask** How might the measurement of the thickness of the card be improved? *(Use a more precise instrument, such as a micrometer, or measure the thickness of a stack of cards and divide by the number of cards.)* Have students determine the thickness of one card and calculate its volume. Using the class average of the calculated volumes, have each student determine the percent error using the average as the accepted value.

QuickLab

Accuracy and Precision

Purpose To measure the dimensions of an object as accurately and precisely as possible and to apply rules for rounding answers calculated from the measurements

Materials

- 3-inch × 5-inch index card
- metric ruler

Procedure

1. Use a metric ruler to measure in centimeters the length and width of an index card as accurately as you can. The hundredths place in your measurement should be estimated.
2. Calculate the area ($A = l \times w$) and the perimeter [$P = 2 \times (l + w)$] of the index card. Write both your unrounded answers and your correctly rounded answers on the chalkboard.

Analyze and Conclude

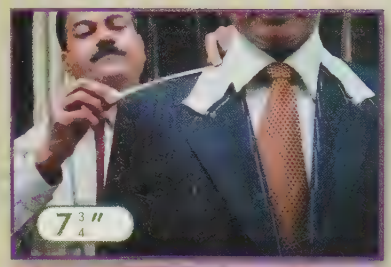
1. **Identify** How many significant figures are in your measurements of length and of width?
2. **Compare** How do your measurements compare with those of your classmates?
3. **Explain** How many significant figures are in your calculated value for the area? In your calculated value for the perimeter? Do your rounded answers have as many significant figures as your classmates' measurements?
4. **Evaluate** Assume that the correct (accurate) length and width of the card are 12.70 cm and 7.62 cm, respectively. Calculate the percent error for each of your two measurements.

3.1 LessonCheck

12. **Review** How can you express a number in scientific notation?
13. **Review** How are accuracy and precision evaluated?
14. **Explain** Why must a given measurement always be reported to the correct number of significant figures?
15. **Calculate** A technician experimentally determined the boiling point of octane to be 124.1°C. The actual boiling point of octane is 125.7°C. Calculate the error and the percent error.
16. **Evaluate** Determine the number of significant figures in each of the following measurements:
    - **a.** 11 soccer players
    - **b.** 0.070 020 meter
    - **c.** 10,800 meters
    - **d.** 0.010 square meter
    - **e.** 5.00 cubic meters
    - **f.** 507 thumbtacks
17. **Calculate** Solve the following and express each answer in scientific notation and to the correct number of significant figures.
    - **a.** $(5.3 \times 10^4) + (1.3 \times 10^4)$
    - **b.** $(7.2 \times 10^{-4}) \div (1.8 \times 10^3)$
    - **c.** $10^4 \times 10^{-3} \times 10^6$
    - **d.** $(9.12 \times 10^{-1}) - (4.7 \times 10^{-2})$
    - **e.** $(5.4 \times 10^4) \times (3.5 \times 10^9)$

BIG IDEA QUANTIFYING MATTER

18. Write a brief paragraph explaining the differences between the accuracy, precision, and error of a measurement.



Lesson Check Answers

12. Write the number as a product of two numbers: a coefficient greater than or equal to one and less than ten, and 10 raised to an integer power.
13. Accuracy compares the measured value to the correct value. Precision compares more than one measurement.
14. The significant figures in a calculated answer depend on the number of significant figures of the measurements and the mathematical operation used in the calculation.
15. error = −1.6°C; percent error = 1.3%
16. **a.** unlimited **b.** 5 **c.** 3 **d.** 2 **e.** 3 **f.** unlimited
17. **a.** 6.6×10^4 **b.** 4.0×10^{-7} **c.** 10^7 **d.** 8.65×10^{-1} **e.** 1.9×10^{14}
18. **BIG IDEA** Accuracy compares a measured value to an accepted value of the measurement; precision compares a measured value to a set of measurements made under similar conditions; and error is the difference between the measured and accepted values.

Watch What You Measure

Just because you live in a digital age doesn't mean that you no longer have to do things by hand. In fact, manually measuring quantities remains an important everyday skill in a number of professions and activities. For example, chefs measure volumes of ingredients in cups (C) or liters (L). Tailors use a tape measure calibrated in inches (in. or ″) to measure length, while biologists use metric rulers or calipers calibrated in centimeters (cm). A ship's navigator uses a sextant to measure the angle between the sun and the horizon. The angle is expressed in degrees (°) and minutes (′).

The next time you make a measurement in lab, keep in mind that lots of other measurers are rounding and noting significant figures, just like you are.

Take It Further

1. Measure What is the measured height of the tomato shown above? How many significant figures does your answer have?

2. Identify What are some other activities that involve measurements done by hand? What units and measuring tools are used?

Differentiated Instruction

L1 STRUGGLING STUDENTS Have students produce a list of several tools used to manually take measurements. The list should include both the name of the tool and what quantity it is used to measure.

ELL ENGLISH LANGUAGE LEARNERS Have students print out pictures of tools commonly used measure and arrange them on a poster board. Students should write a description of the tool and people who might use such a tool for their work or everyday lives.

L3 ADVANCED STUDENTS Have students choose a trade that commonly utilizes computerized measuring tools and research how the systems of measurement have evolved over time in that trade. Encourage students to be creative in what format they use to display their findings.

CHEMISTRY & YOU Have students study the photographs closely. Point out that the most important decision these professionals make when they begin their measurement is not whether to use a manual tool or a technologically advanced tool—the most important decision is to determine the correct tool for the task. The choice of tool helps determine the overall accuracy of the measurement.

Explain to students that the flexible cloth tape measure used by the tailor is divided into increments of 1/16 of an inch. Pose the following question to students: *Imagine that the only tool the tailor had available was a wooden ruler divided into 1-inch increments. How might the use of the wooden ruler affect the outcome of the custom-tailored suit the tailor is constructing?* You may need to assist students in the following ways:

- Custom-tailored clothing is designed to fit the body measurements of the intended wearer.
- Many of the measurements a tailor makes involve curves or circumferences.
- A typical non-retractable cloth tape measure ranges in length from 60 to 96 inches.

Extend

Connect to ARCHITECTURE

Explain to students that one field which makes use of manual systems of measurement is architecture. Discuss how manual tools are utilized by an architect during both the design stages of a project (such as making blueprints or producing models) and by the various tradesmen during the implementation of the architect's design and blueprints. Have students think of a specific example of an architectural project and write a brief paragraph discussing how, during each stage of construction, various manual systems of measurement might be utilized to create a finished product.

Answers

TAKE IT FURTHER

1. 32.72 mm (four significant figures)
2. Answers may vary; possibilities include measuring length of fabric (yards and yardsticks), measuring weight of a letter (ounces and a scale), measuring weight of produce in a store (pounds and a scale).

LESSON 3.2

Key Objectives

- **3.2.1 EXPLAIN** why metric units are easy to use.
- **3.2.2 IDENTIFY** the temperature units scientists commonly use.
- **3.2.3 CALCULATE** the density of a substance.

Engage

CHEMISTRY & YOU Have students study the weather forecast and read the text that opens the section. **Ask** Does the forecast show measurements? *(No; the forecast shows only numbers. A measurement contains both a number and a unit.)*

Activate Prior Knowledge

As a class, create an itemized list of units of measures learned in mathematics and other science courses. Have students classify these measures as linear, squared, cubic, and rate measurements.

Foundations for Reading

BUILD VOCABULARY Have students predict the meanings of the SI prefixes *deci-*, *centi-*, and *milli-* from their knowledge of the words *decimal*, *century*, and *millennium*.

IN ACADEMIC STANDARDS for SCIENCE

C.1.7 Define density and distinguish between materials based on densities. Perform calculations involving density.

3.2 Units of Measurement

C.1.7 Density

CHEMISTRY & YOU

Q: *What's the forecast for tomorrow—hot or cold?* In the weather forecast shown here, the temperatures are in degrees, but without a temperature scale. Will the high temperature tomorrow be 28°C, which is very warm? Or 28°F, which is very cold? Without the correct units, you can't be sure. When you make a measurement, you must assign the correct units to the number. Without the units, it's impossible to communicate the measurement clearly to others.

Key Questions

- *What makes metric units easy to use?*
- *What temperature units do scientists commonly use?*
- *What determines the density of a substance?*

Vocabulary

- International System of Units (SI)
- meter (m) • liter (L)
- kilogram (kg) • gram (g)
- weight • energy
- joule (J) • calorie (cal)
- temperature • Celsius scale
- Kelvin scale • absolute zero
- density

Using SI Units

What makes metric units easy to use?

All measurements depend on units that serve as reference standards. The standards of measurement used in science are those of the metric system. The metric system is important because of its simplicity and ease of use. **All metric units are based on multiples of 10. As a result, you can convert between units easily.** The metric system was originally established in France in 1795. The **International System of Units** (abbreviated **SI**, after the French name, *Le Système International d'Unités*) is a revised version of the metric system. The SI was adopted by international agreement in 1960. There are seven SI base units, which are listed in Table 3.1. From these base units, all other SI units of measurement can be derived. Derived units are used for measurements such as volume, density, and pressure.

All measured quantities can be reported in SI units. Sometimes, however, non-SI units are preferred for convenience or for practical reasons. In this textbook you will learn about both SI and non-SI units.

Learn more about SI units online.

Table 3.1

SI Base Units

Quantity	SI base unit	Symbol
Length	meter	m
Mass	kilogram	kg
Temperature	kelvin	K
Time	second	s
Amount of substance	mole	mol
Luminous intensity	candela	cd
Electric current	ampere	A

Focus on ELL

1 CONTENT AND LANGUAGE For 30 seconds, have students call out what they think of when they hear the words *units of measurement*. Record every response in a list and use the list to create a wordle. Pass out a copy of the wordle to each student. Ask students to deduce the type of measurement with which the class is most and least familiar.

2 FRONTLOAD THE LESSON Ask students to share the common units of measurement used in the country they are from. If the common units are not metric, have the students compare them to metric units.

3 COMPREHENSIBLE INPUT Make some of the items (listed in tables 3.3, 3.4, and 3.5) that represent the dimensions commonly stated in metric units available for students to see and touch. Have each item labeled with the unit that it represents.

Table 3.2

Commonly Used Metric Prefixes

Prefix	Symbol	Meaning	Factor
mega	M	1 million times larger than the unit it precedes	10^6
kilo	k	1000 times larger than the unit it precedes	10^3
deci	d	10 times smaller than the unit it precedes	10^{-1}
centi	c	100 times smaller than the unit it precedes	10^{-2}
milli	m	1000 times smaller than the unit it precedes	10^{-3}
micro	μ	1 million times smaller than the unit it precedes	10^{-6}
nano	n	1 billion times smaller than the unit it precedes	10^{-9}
pico	p	1 trillion times smaller than the unit it precedes	10^{-12}

Units of Length Size is an important property of matter. In SI, the basic unit of length, or linear measure, is the **meter (m).** All measurements of length can be expressed in meters. (The length of a page in this book is about one fourth of a meter.) For very large and very small lengths, however, it may be more convenient to use a unit of length that has a prefix. Table 3.2 lists the prefixes in common use. For example, the prefix *milli-* means 1/1000 (one-thousandth), so a millimeter (mm) is 1/1000 of a meter, or 0.001 m. A hyphen (-) measures about 1 mm.

For large distances, it is usually most appropriate to express measurements in kilometers (km). The prefix *kilo-* means 1000, so 1 km equals 1000 m. A standard marathon distance race of about 42,000 m is more conveniently expressed as 42 km (42 × 1000 m). Table 3.3 summarizes the relationships among metric units of length.

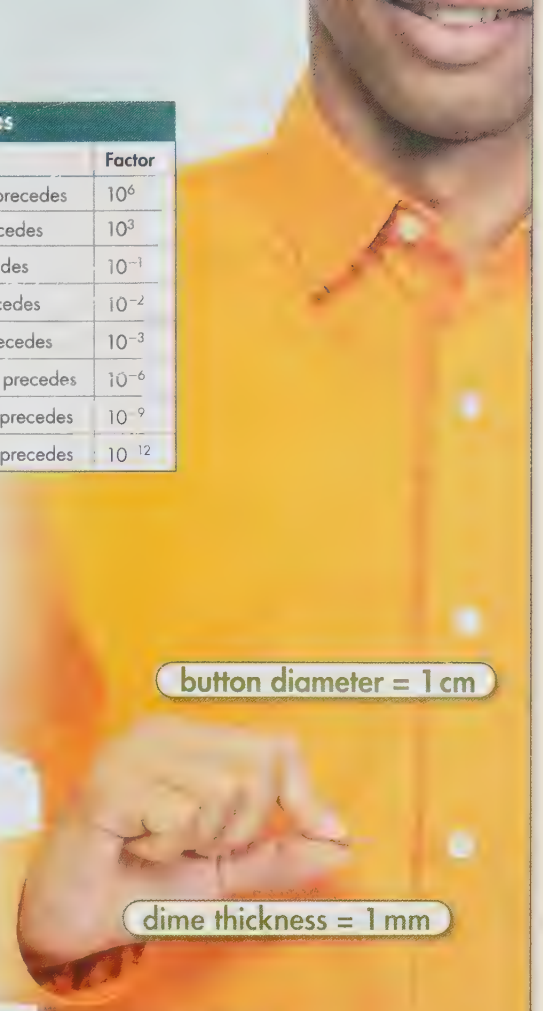

Table 3.3

Metric Units of Length

Unit	Symbol	Relationship	Example	
Kilometer	km	1 km = 10^3 m	length of about five city blocks	≈ 1 km
Meter	m	base unit	height of doorknob from the floor	≈ 1 m
Decimeter	dm	10^1 dm = 1 m	diameter of large orange	≈ 1 dm
Centimeter	cm	10^2 cm = 1 m	diameter of shirt button	≈ 1 cm
Millimeter	mm	10^3 mm = 1 m	thickness of dime	≈ 1 mm
Micrometer	μm	10^6 μm = 1 m	diameter of bacterial cell	≈ 1 μm
Nanometer	nm	10^9 nm = 1 m	thickness of RNA molecule	≈ 1 nm

READING STRATEGY Have students look at Tables 3.1, 3.3, 3.4, and 3.5. Tell students to read the title of each table and the column heads before looking at the information in the table. Have students write in their vocabulary notebook any words from these tables with which they are unfamiliar.

Explain

Using SI Units

MAKE A CONNECTION Explain that with the exception of those working in the sciences, the United States is the only country *not* using the metric system as a routine method of measurement. **Ask** What are some real-world examples of applications in the United States in which the metric system is the commonly accepted unit of measure? *(Acceptable answers include 35-mm film; meter distances in track and field; the dimensions of tools (wrenches) and hardware (bolts); power rating in watts of appliances, and the occasional road sign.)*

USE VISUALS Have students examine Table 3.2. Discuss with students how SI prefixes are always in increments of ten and can be expressed using scientific notation. **Ask** What does the prefix *kilo-* mean? *(The prefix* kilo- *means 1000 times larger than the unit it precedes.)* **Ask** How is this prefix represented in scientific notation? *(10^3)* **Ask** How much larger is the prefix *centi-* compared to the prefix *micro-?* Show students how to make this comparison by writing the following on the board:

$$\frac{\text{centi-}}{\text{micro-}} = \frac{10^{-2}}{10^{-6}}$$
$$= 10^{-2-(-6)}$$
$$= 10^{(-2+6)}$$
$$= 10^4$$

Remind students that when dividing numbers in scientific notation, the exponent of the denominator is subtracted from the exponent of the numerator. Convey the importance of knowing how to interpret an answer. For instance, point out that the difference of 10^4 means that the *centi-* is a measure that is 10,000 times larger than the *micro-*.

Professional Development Note

SI Units of Distance and Time

In 1790, with the establishment of the metric system, the French became the first to adopt measurement standards that were close to being precise. The meter was defined as one ten-millionth of the distance from the equator to the North Pole along the meridian that passes through Paris. The second was defined as 1/86,400 of the average day. The definitions of these and other base units have since become more precise. The meter is now defined as the distance traveled by light in a vacuum in 1/299,792,458 of a second. The second is now defined in terms of the number of cycles of radiation given off by a specific isotope of the element cesium.

Explain

Using SI Units

APPLY CONCEPTS Point out that data can be reported accurately in various related units (mm, cm, m), but it is best to choose the unit closest in scale to the object being measured—a unit that may or may not be an SI base unit. Share with the class the following:

- the unit of mass most often used by chemists is the gram—not the kilogram. Explain that kilograms of chemicals are too large for most laboratory experiments.
- the density of a gas is typically measured in grams per liter; the densities of most solids and liquids are typically measured in grams per cubic centimeter.
- the milliliter is the most common unit of volume used by laboratory chemists. The cubic meter is much too large a volume for most laboratory experiments.

Explore

Teacher Demo

PURPOSE Students will be introduced to laboratory equipment used to measure volume.

MATERIALS sets of Erlenmeyer flasks, buret, graduated cylinder, beaker, and volumetric flask; water; food coloring

SAFETY Have students wear goggles to emphasize safety in the laboratory.

PROCEDURE Before the demonstration, fill the glassware with water and add a few drops of food coloring. Place the sets at various stations around the classroom. Assign groups of students to each station. As students inspect the glassware, explain that beakers, Erlenmeyer flasks, and graduated cylinders are used to measure approximate volumes. Volumetric flasks and burets allow measurements that are more precise. **Ask** What is the appropriate instrument to use to measure a large volume, such as 1 L, accurately? *(Students should choose the volumetric flask.)*

EXPECTED OUTCOME Students should be able to select the appropriate glassware when presented with the volumetric parameters for an experiment.

Figure 3.5 Volumetric Units The volume of 20 drops of liquid from a medicine dropper is about 1 mL. This is the same volume as that of a sugar cube, which is 1 cm on each edge; 1 cm^3 = 1 mL. A liter bottle has a volume of 1 L, or 1000 mL. **Describe** *What is the volume of a 2-L bottle in cubic centimeters?*

Units of Volume The space occupied by any sample of matter is called its volume. You calculate the volume of any cubic or rectangular solid by multiplying its length by its width by its height. The unit for volume is thus derived from units of length. The SI unit of volume is the amount of space occupied by a cube that is 1 m along each edge. This volume is a cubic meter (m^3). An automatic dishwasher has a volume of about 1 m^3.

A more convenient unit of volume for everyday use is the liter, a non-SI unit. A **liter (L)** is the volume of a cube that is 10 centimeters (10 cm) along each edge (10 cm × 10 cm × 10 cm = 1000 cm^3 = 1 L). A decimeter (dm) is equal to 10 cm, so 1 L is also equal to 1 cubic decimeter (dm^3). A smaller non-SI unit of volume is the milliliter (mL); 1 mL is 1/1000 of a liter. Thus, there are 1000 mL in 1 L. Because 1 L is defined as 1000 cm^3, 1 mL and 1 cm^3 are the same volume. The units milliliter and cubic centimeter are thus used interchangeably. Figure 3.5 gives you some idea of the relative sizes of a liter and a milliliter. Table 3.4 summarizes the relationships among common metric units of volume.

There are many devices for measuring liquid volumes, including graduated cylinders, pipets, burets, volumetric flasks, and syringes. Note that the volume of any solid, liquid, or gas will change with temperature (although the change is much more dramatic for gases). Consequently, accurate volume-measuring devices are calibrated at a given temperature—usually 20 degrees Celsius (20°C), which is about normal room temperature.

Table 3.4

Metric Units of Volume

Unit	Symbol	Relationship	Example
Liter	L	base unit	quart of milk ≈ 1 L
Milliliter	mL	10^3 mL = 1 L	20 drops of water ≈ 1 mL
Cubic centimeter	cm^3	1 cm^3 = 1 mL	cube of sugar ≈ 1 cm^3
Microliter	µL	10^6 µL = 1 L	crystal of table salt ≈ 1 µL

Differentiated Instruction

L1 STRUGGLING STUDENTS Recreate Table 3.2 on the board, adding a fifth column that shows the factor of each prefix as a whole number or fraction. For example, *mega-* represents a factor of 1,000,000 and *deci-* represents a factor of 1/10.

LPR LESS PROFICIENT READERS Have students search magazines and newspapers for examples of SI units. Have them report seasonal day/night temperature ranges for their countries of origin.

L3 ADVANCED STUDENTS Have students research the efforts to make the metric system standard in the United States. Who has promoted the change? What progress has been made? What obstacles remain?

Table 3.5

Metric Units of Mass

Unit	Symbol	Relationship	Example	
Kilogram (base unit)	kg	1 kg = 10^3 g	small textbook	≈ 1 kg
Gram	g	1 g = 10^{-3} kg	dollar bill	≈ 1 g
Milligram	mg	10^3 mg = 1 g	ten grains of salt	≈ 1 mg
Microgram	μg	10^6 μg = 1 g	particle of baking powder	≈ 1 μg

Units of Mass The mass of an object is measured in comparison to a standard mass of 1 **kilogram (kg),** which is the basic SI unit of mass. A kilogram was originally defined as the mass of 1 L of liquid water at 4°C. A cube of water at 4°C measuring 10 cm on each edge would have a volume of 1 L and a mass of 1000 grams (g), or 1 kg. A **gram (g)** is 1/1000 of a kilogram; the mass of 1 cm^3 of water at 4°C is 1 g. The relationships among units of mass are shown in Table 3.5.

You can use a platform balance to measure the mass of an object. The object is placed on one side of the balance, and standard masses are added to the other side until the balance beam is level. The unknown mass is equal to the sum of the standard masses. Laboratory balances range from very sensitive instruments with a maximum capacity of only a few milligrams to devices for measuring quantities in kilograms. An analytical balance is used to measure objects of less than 100 g and can determine mass to the nearest 0.0001 g (0.1 mg).

Weight is a force that measures the pull on a given mass by gravity. Weight, a measure of force, is different from mass, which is a measure of the quantity of matter. The weight of an object can change with its location. For example, an astronaut on the surface of the moon weighs one sixth of what he weighs on Earth. The reason for this difference is that the force of Earth's gravity is about six times greater than that of the moon. The astronaut in Figure 3.6 is in free fall as he orbits Earth and is therefore weightless. Although it's possible for an object to become weightless, it can never become massless.

Figure 3.6 Weightlessness
An astronaut in orbit is weightless, but not massless. The astronaut's mass remains constant regardless of location or motion.

Units of Energy The capacity to do work or to produce heat is called **energy.** Like any other quantity, energy can be measured. The SI unit of energy is the **joule (J),** named after the English physicist James Prescott Joule (1818–1889). A common non-SI unit of energy is the calorie. One **calorie (cal)** is the quantity of heat that raises the temperature of 1 g of pure water by 1°C. Conversions between joules and calories can be carried out using the following relationships:

$$1\ J = 0.2390\ cal \qquad 1\ cal = 4.184\ J$$

In this book, you will see energy values expressed in both joules and calories, as well as kilojoules (kJ) and kilocalories (kcal). A kilojoule is 1000 joules; a kilocalorie is 1000 calories.

UbD Check for Understanding

BIGIDEA **QUANTIFYING MATTER** Assess students' understanding of the appropriate choice of units for a given measurement by listing the following measurements on the board: liquid volume, body temperature, height, and body mass. Ask students to identify the appropriate SI unit for the measurement and indicate whether the unit is a base unit or derived unit. *(liquid volume: liter, derived; body temperature: Kelvin, base; height: meter, base; body mass: kilogram, base)*

ADJUST INSTRUCTION If students are still struggling with the concept of derived units, have students reread the first paragraph of the Using SI Units section, and then review the derivation of the liter for volume as an example of how an SI unit can be used to calculate a common non-SI unit.

Explore

Class Activity

PURPOSE Students will practice weighing groups of objects.

MATERIALS balance with a precision of at least 0.01 g, sets of 10 pennies each separated according to minting dates between 1970 and the present. Make sure that sets include pre- and post-1982 minting dates.

SAFETY Have student wear goggles when weighing the pennies.

PROCEDURE Have students weigh three five-penny samples from each set of pennies and record their data. Have students calculate the average mass of a penny and plot the average mass versus the year it was minted.

EXPECTED OUTCOME Students should observe slight variations in mass from year to year due to chance error, and a dramatic decrease in mass between 1982 and 1983. Note that pennies minted before 1982 are mostly copper; pennies minted after 1982 are mostly zinc, which is less dense than copper. Ask students to propose a hypothesis for their findings. *(Acceptable answers include a change in the composition of the penny.)* Instruct students to keep their graph, results, and hypothesis for the discussion of density on page 80.

Answers

FIGURE 3.5 2000 cm^3

Explain

Temperature Scales

USE VISUALS Have students inspect the thermometers in Figure 3.7. **Ask** Which thermometer is more precise? *(the bulb thermometer)* **Ask** Which is the least precise? *(the bimetallic strip thermometer)* **Ask** Why do you think a chef would choose the less precise thermometer for determining when the turkey is done? *(The range of the bimetallic strip thermometer is greater than that of the bulb thermometer and more appropriate for an oven environment.)*

Temperature Scales

What temperature units do scientists commonly use?

When you hold a glass of hot water, the glass feels hot because heat transfers from the glass to your hand. When you hold an ice cube, it feels cold because heat transfers from your hand to the ice cube. **Temperature** is a measure of how hot or cold an object is. An object's temperature determines the direction of heat transfer. When two objects at different temperatures are in contact, heat moves from the object at the higher temperature to the object at the lower temperature. In Chapter 13, you will learn how the temperature of an object is related to the energy and motion of particles.

Almost all substances expand with an increase in temperature and contract as the temperature decreases. (A very important exception is water.) These properties are the basis for the common bulb thermometer. The liquid in the thermometer expands and contracts more than the volume of the glass, producing changes in the column height of liquid. Figure 3.7 shows two different types of thermometers.

Several temperature scales with different units have been devised.

Scientists commonly use two equivalent units of temperature, the degree Celsius and the kelvin. The Celsius scale of the metric system is named after the Swedish astronomer Anders Celsius (1701–1744). It uses two readily determined temperatures as reference temperature values: the freezing point and the boiling point of water. The **Celsius scale** sets the freezing point of water at 0°C and the boiling point of water at 100°C. The distance between these two fixed points is divided into 100 equal intervals, or degrees Celsius (°C).

Another temperature scale used in the physical sciences is the Kelvin, or absolute, scale. This scale is named for Lord Kelvin (1824–1907), a Scottish physicist and mathematician. On the **Kelvin scale,** the freezing point of water is 273.15 kelvins (K), and the boiling point is 373.15 K. Notice that with the Kelvin scale, the degree sign is not used.

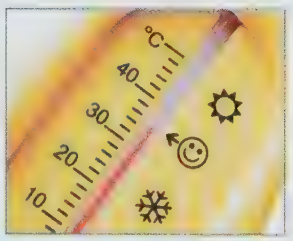

Figure 3.7 Thermometers
A bulb thermometer contains a liquid such as alcohol or mineral spirits. A dial thermometer, often used to measure the cooking temperature of meats, contains a coiled bimetallic strip.

Professional Development Note

Cryogenics

William Francis Giauque was awarded the 1949 Nobel Prize in chemistry for his research regarding the properties of matter at temperatures close to absolute zero. The study of phenomena at extremely low temperatures is known as cryogenics. Giauque's findings made it possible to calculate and predict chemical equilibria and the behavior of some chemical reactions.

Prior to Giauque's research, the coldest temperature achieved in a laboratory was 0.8 K in 1910 by another Nobel laureate, Heike Kamerlingh Onnes. By 2000, the coldest temperature achieved in a laboratory was 500 pK, or 0.000 000 000 5 K. In comparison, the lowest temperature known outside a laboratory is about 2.6 K, which is the estimated background temperature of deep space.

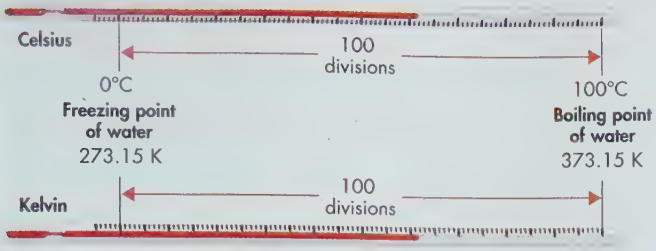

Figure 3.8 Temperature Scales
A 1°C change on the Celsius scale is equal to a 1 K change on the Kelvin scale.
Interpret Diagrams *What is a change of 10°C equivalent to on the Kelvin scale?*

Figure 3.8 compares the Celsius and Kelvin scales. A change of one degree on the Celsius scale is equivalent to one kelvin on the Kelvin scale. The zero point on the Kelvin scale, 0 K, or **absolute zero**, is equal to −273.15°C. For problems in this text, you can round −273.15°C to −273°C. Because one degree on the Celsius scale is equivalent to one kelvin on the Kelvin scale, converting from one temperature to another is easy. You simply add or subtract 273, as shown in the following equations:

$$K = °C + 273$$
$$°C = K - 273$$

CHEMISTRY & YOU

Q: *In a few countries, such as the United States, metric units are not commonly used in everyday measurements. What temperature units are used for a typical weather forecast in the United States? What about for a country that uses the metric system, such as Australia or Japan?*

Sample Problem 3.7

Converting Between Temperature Scales

Normal human body temperature is 37°C. What is this temperature in kelvins?

1 Analyze **List the known and the unknown.**
Use the known value and the equation K = °C + 273 to calculate the temperature in kelvins.

KNOWN
Temperature in °C = 37°C

UNKNOWN
Temperature in K = ? K

2 Calculate **Solve for the unknown.**

Substitute the known value for the Celsius temperature into the equation and solve.

$K = °C + 273 = 37 + 273 = 310\ K$

3 Evaluate **Does the result make sense?** You should expect a temperature in this range, since the freezing point of water is 273 K and the boiling point of water is 373 K; normal body temperature is between these two values.

19. The element silver melts at 960.8°C and boils at 2212°C. Express these temperatures in kelvins.

20. Liquid nitrogen boils at 77.2 K. What is this temperature in degrees Celsius?

Foundations for Math

CHECK ANSWERS When converting between the Kelvin and Celsius scales, the conversion itself is straightforward. However, students often become confused as to when the conversion factor should be added and when it should be subtracted. Remind students that the value for a temperature in the Kelvin scale is always greater numerically than its equivalent on the Celsius scale.

In **Sample Problem 3.7**, 310 is numerically greater than 37, so the conversion is correct.

Explain

Temperature Scales

USE VISUALS Direct students to Figure 3.8. Have students compare the freezing point of water on the Celsius and Kelvin temperature scales *(0°C and 273.15 K)* **Ask** What temperature scale has its zero point at absolute zero? *(the Kelvin scale)* **Ask** Why do you think scientists use more than one temperature scale? *(Acceptable answers include that one scale may be more convenient than the other depending on what is being measured; for example, extremely low temperatures are all negative numbers when expressed in degrees Celsius but positive when expressed in kelvins.)*

Extend

Connect to PHYSICS

Ask students to determine a way to represent a temperature given in degrees Fahrenheit to the Kelvin scale. (Convert the temperature from °F to °C using the formula $°C = \frac{5}{9}(°F - 32)$ and then convert the temperature from °C to K.) Explain that absolute zero is defined as precisely 0 K on the Kelvin scale and as –273.15° on the Celsius scale. Ask students to research if there is another unit for temperature that has a relationship to the Fahrenheit scale that is similar to the relationship between the Celsius scale and the Kelvin scale. *(Absolute zero is precisely equivalent to 0 R on the Rankine scale, which is the Fahrenheit equivalent of the Kelvin scale. 0 R = –459.67° on the Fahrenheit scale.)*

CHEMISTRY & YOU In the United States, temperatures are typically reported in degrees Fahrenheit (°F). In countries that have adopted the metric system, temperatures are reported in degrees Celsius (°C).

Sample Practice Problem

At 10,000 feet above sea level, water boils at 90°C. What is this temperature in kelvins? *(363 K)*

Answers

FIGURE 3.8 10 K

Explain

Density

USE VISUALS Direct students to the photograph in Figure 3.9. **Ask** What property of a cranberry allows it to float on the water rather than sink to the bottom? *(Cranberries are less dense than water.)* **Ask** What measurements would you need to make to determine whether an object would float in water? *(Measure the object's volume and mass; then compute its density and compare the result to the density of water.)*

USE VISUALS Direct students' attention to Figure 3.10. Point out that the samples in the figure are cubes. **Ask** What would be the volume of a 10-g *sphere* of each of the substances shown? *(Li: 19 cm^3; H_2O: 10 cm^3; and Pb: 0.88 cm^3)* Point out that even though the shape of the sample changed, its density did not. As long as the samples have the same mass and the same density, their shape has no bearing on their volume.

MAKE A CONNECTION If students performed the *Mass of a Penny* activity, have them refer to the explanation of the results. **Ask** How can you use density to test the hypothesis that the composition of the penny changed? *(Determine the volume and mass of a pre- and post-1982 penny. Calculate the density of each and compare them. If the densities changed, the composition of the penny must have changed.*

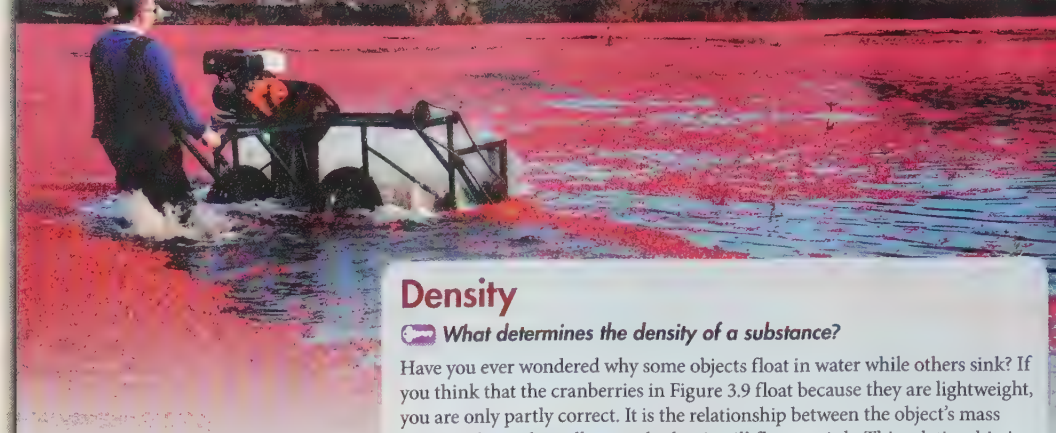

Figure 3.9 Floating on Water
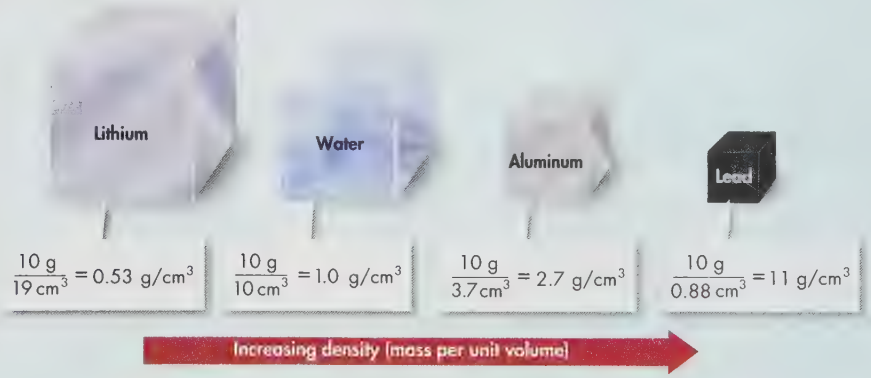
Cranberries are less dense than water, so they float. Farmers make use of this property when it's time to harvest the crop.

Density

What determines the density of a substance?

Have you ever wondered why some objects float in water while others sink? If you think that the cranberries in Figure 3.9 float because they are lightweight, you are only partly correct. It is the relationship between the object's mass and its volume that tells you whether it will float or sink. This relationship is called density. **Density** is the ratio of the mass of an object to its volume.

$$\text{Density} = \frac{\text{mass}}{\text{volume}}$$



A 10.0-cm^3 piece of lead, for example, has a mass of 114 g. You can calculate the density of lead by substituting into the equation above.

$$\frac{114\ \text{g}}{10.0\ \text{cm}^3} = 11.4\ \text{g/cm}^3$$

Note that when mass is measured in grams, and volume in cubic centimeters, density has units of grams per cubic centimeter (g/cm^3). The SI unit of density is kilograms per cubic meter (kg/m^3).

Figure 3.10 compares the density of four substances: lithium, water, aluminum, and lead. Why does each 10-g sample have a different volume? The volumes vary because the substances have different densities. **Density is an intensive property that depends only on the composition of a substance, not on the size of the sample.** With a mixture, density can vary because the composition of a mixture can vary.

Figure 3.10 Comparing Densities
A 10-g sample of pure water has less volume than 10 g of lithium, but more volume than 10 g of lead or 10 g of aluminum. The faces of the cubes are shown actual size.
Predict *Which of the solids shown will sink in water?*

Differentiated Instruction

ELL ENGLISH LANGUAGE LEARNERS Have students find photos of objects containing substances from Table 3.6. They could label each photo with the substance's name in multiple languages as well as the density, whose units are part of a universal language.

LPR LESS PROFICIENT READERS Using context clues, have students orally describe in their own words, or with an analogy, the meaning of the term *intensive property*. **Ask** What other properties may be intensive? *(Acceptable answers include temperature and color.)*

L3 ADVANCED STUDENTS Point out that the specific gravity is the ratio of the density of a material to that of water. Have students conduct create and conduct an experiment for determining the specific gravity of two different liquids. Tell students to use a hydrometer in their experiment and ask students to prepare a lab report detailing their research.

Interpret Data

Densities of Some Common Materials			
Solids and Liquids		Gases	
Material	Density at 20°C (g/cm³)	Material	Density at 20°C (g/L)
Gold	19.3	Chlorine	2.95
Mercury	13.6	Carbon dioxide	1.83
Lead	11.3	Argon	1.66
Aluminum	2.70	Oxygen	1.33
Table sugar	1.59	Air	1.20
Corn syrup	1.35–1.38	Nitrogen	1.17
Water (4°C)	1.000	Neon	0.84
Corn oil	0.922	Ammonia	0.718
Ice (0°C)	0.917	Methane	0.665
Ethanol	0.789	Helium	0.166
Gasoline	0.66–0.69	Hydrogen	0.084

Table 3.6 Density is the mass per unit volume of a material.

a. Compare Why do you think the densities of the gases are reported in units that are different from those used for the densities of the solids and liquids?

b. Predict Would a balloon filled with carbon dioxide sink or rise in air? Explain.

c. Infer Why are the densities of corn syrup and gasoline expressed as a range of values?

Note the units here: Densities of the solids and liquids are expressed in g/cm³. Densities of the gases are expressed in g/L.

What do you think will happen if corn oil is poured into a container of water? Using Table 3.6, you can see that the density of corn oil is less than the density of water. For that reason, the oil floats on top of the water. Figure 3.11 shows different liquids forming distinct layers in a container due to differences in density. For example, the corn syrup (colored red), sinks below the water (colored green) because the density of corn syrup is greater than the density of water.

You have probably seen a helium-filled balloon rapidly rise to the ceiling when it is released. Whether a gas-filled balloon will sink or rise when released depends on how the density of the gas compares with the density of air. Helium is less dense than air, so a helium-filled balloon rises. The densities of various gases are listed in Table 3.6.

What happens to the density of a substance as its temperature increases? Experiments show that the volume of most substances increases as the temperature increases. Meanwhile, the mass remains the same despite the temperature and volume changes. Remember that density is the ratio of an object's mass to its volume. So if the volume changes with temperature (while the mass remains constant), then the density must also change with temperature. The density of a substance generally decreases as its temperature increases. As you will learn in Chapter 15, water is an important exception. Over a certain range of temperatures, the volume of water increases as its temperature decreases. Ice, or solid water, floats because it is less dense (0.917 g/cm³) than liquid water (1.000 g/cm³).

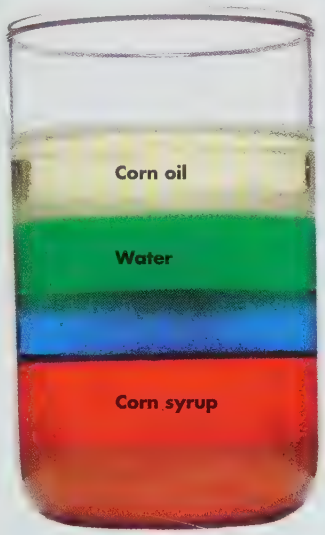


Figure 3.11 Liquid Layers Because of differences in density, the liquids separate into layers.
Compare *Is the blue-colored liquid more or less dense than water?*

Professional Development Note

Specific Gravity

Specific gravity is the ratio of the density of a substance to the density of a reference substance.

$$\text{Specific gravity} = \frac{\text{density of substance}}{\text{density of reference substance}}$$

Specific gravity is basically the heaviness of a substance compared to that of water, and it is expressed without units. The reference substance for solids and liquids is usually water at 4°C. The density of water at that temperature is 1.0000 g/mL.

Physicians use the measured specific gravity of a patient's urine to help diagnose certain diseases, such as diabetes. Auto mechanics measure the specific gravity of antifreeze in radiators during tune-ups.

Explore

Class Activity

PURPOSE Students will calculate density from a mass-volume graph.

MATERIALS 3 or 4 different-sized cubes of a material such as wood, metal, or marble; metric ruler; balance

PROCEDURE Have student volunteers measure the masses of the cubes, measure the lengths of the cubes, and calculate their volumes. On the board or an overhead projector, record the masses and volumes. Construct a mass-volume graph (mass on the *y*-axis) and plot the data. Remind students how to calculate the slope of the line using rise over run. **Ask** What does the slope of this line indicate? *(Elicit that the slope of the line is the ratio of mass/volume and has the units of g/cm³, which is the unit of density.)*

EXPECTED OUTCOME The mass and volume data should lie along a straight line. **Ask** What is the ratio of mass to volume of a substance? *(density)*

Answers

FIGURE 3.10 aluminum and lead

FIGURE 3.11 more dense

INTERPRET DATA **a.** Gases at ambient temperature and pressure take up much more volume than liquids or solids. **b.** Sink; carbon dioxide is more dense than air. **c.** Corn syrup and gasoline are mixtures with variable composition, so they have variable density.

Explain

Density

Sample Practice Problem

What is the density of an object whose mass is 142.5 grams and whose volume is 7.5 cm^3? *(19 g/cm^3)*

Extend

Remind students of other equations they have manipulated, such as the formula for the area of a triangle, and have students state the properties of equality they used to solve the formula for a specified variable. Then ask students to show how the density equation can be manipulated to determine the mass or volume of an object, if the density of a substance is known. *(mass × density = volume; volume × density = mass)*

Evaluate

Informal Assessment

Have students identify the most common unit of density and explain why density is a derived SI unit rather than a base unit. *(g/cm^3; it is a derived unit because it is calculated from units of mass and length. A gram is 10^{-3} kilogram, and a centimeter is 10^{-2} meter. Kilograms and meters are base SI units.)* **Ask** How can density be used to determine whether a metal washer is aluminum or zinc? *(Measure and compare the density of the washer to the accepted density values of aluminum and zinc.)* Then have students complete the 3.2 Lesson Check.

Reteach

Review Tables 3.3, 3.4, 3.5, and 3.6 with students. Review the SI base unit listed in each table, pronunciations of the derived units, and the use of the prefixes to determine the numerical relationships between the base unit and the derived units.

Sample Problem 3.8

Calculating Density

A copper penny has a mass of 3.1 g and a volume of 0.35 cm^3. What is the density of copper?

1 Analyze **List the knowns and the unknown.**
Use the known values and the equation for density to solve the problem.

KNOWNS	UNKNOWN
mass = 3.1 g	density = ? g/cm^3
volume = 0.35 cm^3	

2 Calculate **Solve for the unknown.**

Start with the equation for density.

$$\text{Density} = \frac{\text{mass}}{\text{volume}}$$

The calculated answer must be rounded to two significant figures.

Substitute the known values for mass and volume and then calculate.

$$\text{Density} = \frac{3.1\ g}{0.35\ cm^3} = 8.8571\ g/cm^3 = 8.9\ g/cm^3$$

3 Evaluate **Does the result make sense?** A piece of copper with a volume of about 0.3 cm^3 has a mass of about 3 grams. About three times that volume of copper, 1 cm^3, should have a mass three times larger, about 9 grams. This estimate is close to the calculated result.

21. A student finds a shiny piece of metal that she thinks is aluminum. In the lab, she determines that the metal has a volume of 245 cm^3 and a mass of 612 g. Calculate the density. Is the metal aluminum?

22. A bar of silver has a mass of 68.0 g and a volume of 6.48 cm^3. What is the density of silver?

3.2 LessonCheck

23. Review Why are metric units easy to use?

24. Identify What temperature units do scientists commonly use?

25. Review What determines density?

26. Identify Write the name and symbol of the SI units for mass, length, volume, and temperature.

27. Define Write the symbol and meaning of each prefix below.
a. *milli-* **b.** *nano-* **c.** *deci-* **d.** *centi-*

28. List Arrange the following units in order from largest to smallest: m^3, mL, cL, µL, L, dL.

29. Calculate What is the volume of a paperback book 21 cm tall, 12 cm wide, and 3.5 cm thick?

30. Compare State the difference between mass and weight.

31. Calculate Surgical instruments may be sterilized by heating at 170°C for 1.5 hr. Convert 170°C to kelvins.

32. Calculate A weather balloon is inflated to a volume of 2.2×10^3 L with 374 g of helium. What is the density of helium in grams per liter?

33. Apply Concepts A 68-g bar of gold is cut into three equal pieces. How does the density of each piece compare to the density of the original gold bar?

34. Interpret Data Look up the densities of the elements in Group 1A on page R2. Which Group 1A elements are less dense than pure water at 4°C?

35. Explain How does density vary with temperature?

Lesson Check Answers

23. All metric units are based on multiples of 10, which makes them easy to use.

24. the degree Celsius and the kelvin

25. Density is an intensive property that depends only on the composition of a substance, not on the size of the sample. Density = mass/volume

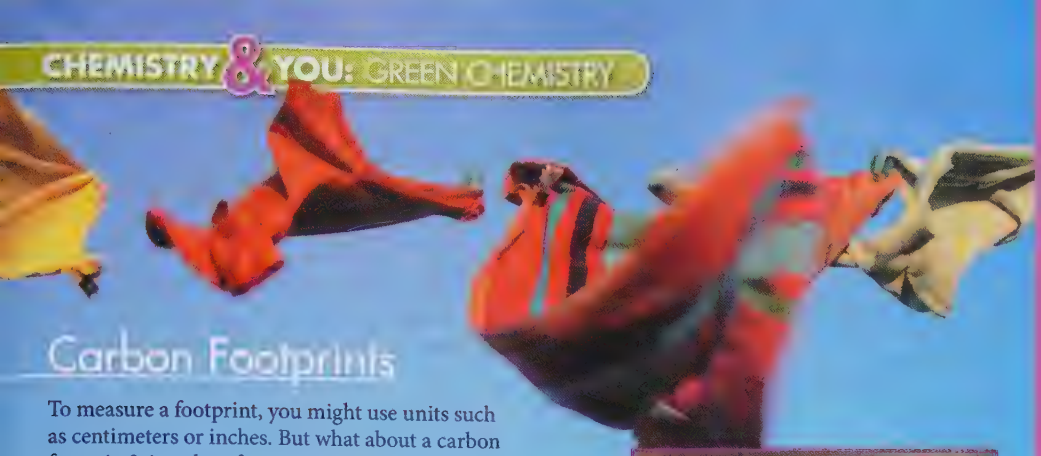
26. mass, kilogram (kg); length, meter (m); volume, cubic meter (m^3); temperature, kelvin (K)

27. **a.** m; 10^{-3} of the unit
b. n; 10^{-9} of the unit
c. d; 10^{-1} of the unit
d. c; 10^{-2} of the unit

28. m^3, L, dL, cL, mL, µL

29. 8.8×10^2 cm^3

30. Mass is a measure of the amount of matter in an object. Weight is a measure of the force of gravity on an object.



31. 443 K

32. 1.7×10^{-1} g/L

33. All the densities are equal.

34. Li, Na, and K are less dense than water.

35. Density generally decreases when temperature increases.

Carbon Footprints

To measure a footprint, you might use units such as centimeters or inches. But what about a carbon footprint? A carbon footprint is a measure of how much greenhouse gas is released into the atmosphere by a person, country, or industry. Greenhouse gases, such as carbon dioxide (CO_2) and methane (CH_4), are gases that contribute to global warming.

Any activity that involves the burning of fossil fuels results in carbon dioxide emissions. Car travel, air travel, home heating and cooling, and electricity usage all add to an individual's carbon footprint. Your own carbon footprint is the total mass of CO_2 that you put into the atmosphere over the course of a year. This quantity can be expressed in metric tons (t) of CO_2 per year. A metric ton equals 1000 kg. So, the units of your carbon footprint can be abbreviated as: t CO_2/yr or 10^3 kg CO_2/yr.

CARBON COSTS Your choices affect the size of your carbon footprint. For example, using a clothes dryer consumes electricity, but hanging wet laundry on a clothesline does not. The things you buy also contribute to your carbon footprint. Not only is energy required to make these goods, but the goods themselves (such as TVs) may consume energy.

FOOTPRINT UNITS The carbon footprint of fresh produce can be expressed in g CO_2 per serving. Cars require different units: kg CO_2 per gallon of gasoline. For planes, the units are kg CO_2 per passenger mile.

Take It Further

1. Calculate A car emits 8.6 kg of CO_2 per gallon of unleaded gas. How much CO_2 is produced if the car burns 2.5 gal of fuel?

2. Infer What factors do you think determine the carbon footprint of an apple? Why might the carbon footprints of two apples in the same store differ substantially?

21st Century Learning To be successful in the 21st century, students need skills and learning experiences that extend beyond subject matter mastery. The following project helps students build the following 21st Century Skills: *Global Awareness; Financial, Economic, Business, and Entrepreneurial Literacy; Creativity and Innovation; Communication and Collaboration; Information, Media, and Technology Skills; Initiative and Self-Direction; and Productivity and Accountability.*

Divide the class into groups of three to five students. Pose the following challenge to students: *Estimate your individual personal carbon footprint for a day. As a group, compile your results and prepare a graphical representation to depict the activities that contribute the most to the personal carbon footprint of your group.* Students should include possible strategies they could implement to reduce that amount.

CHEMISTRY & YOU The idea of a *carbon footprint* is a relatively new concept, and it is not always easy to understand just what determines an object's or an individual's personal carbon footprint. Explain to students first how a particular object's carbon footprint is determined. Take a common classroom item such as a chair as an example. Explain how each step in production and transportation of that object adds to its carbon footprint. For example, consider the CO_2 released by the factory while the chair is produced and the CO_2 released by the delivery truck that transported the chair from the factory to the warehouse to the school.

After explaining factors that contribute to an individual object's carbon footprint, talk to students about how those objects then contribute to every individual's own carbon footprint. Pose the following question to students: *Which would contribute more to your personal carbon footprint, driving a car to school or riding a bus?* You may need to assist students in the following ways:

- A bus produces more CO_2 per mile.
- A bus carries significantly more people per trip.
- Sharing a ride with other people reduces a person's individual carbon footprint.

Extend

Connect to ECONOMICS

A major issue in the world today concerning carbon footprints is that with current technologies, it often costs significantly more to create a product with a low carbon footprint. For example, an LED-type bulb has a lower carbon footprint than a similar incandescent bulb because it lasts significantly longer before it must be replaced. However, an LED is more expensive to produce than a bulb with a similar output to its incandescent counterpart.

Have students work in groups of three to discover examples in the world around them where the issue of price versus carbon footprint might be an issue, and report their findings to the class.

Answers

21. density = 2.50 g/cm^3; no

22. 10.5 g/cm^3

TAKE IT FURTHER

1. 21.5 kg CO_2
2. Factors might include the amount of fertilizer used to help the apple tree grow and the amount of energy used to harvest, package, and ship the apples. Two apples in the same store might come from different orchards that require different amounts of energy to grow, harvest, package, and ship the apples.

LESSON 3.3

Key Objectives

3.3.1 EXPLAIN what happens when a measurement is multiplied by a conversion factor.

3.3.2 DESCRIBE the kinds of problems that can be easily solved using dimensional analysis.

Additional Resources

- Reading and Study Workbook, Lesson 3.3
  Core Teaching Resources, Lesson 3.3 Review

PearsonChem.com

Engage

CHEMISTRY & YOU Have students examine the photograph that opens the section. **Ask** Has anyone ever noticed a chart or table in a bank or in the newspaper relating the values of foreign currency to the U.S. dollar? *(yes or no)* Explain that these are tables are called currency conversion tables. These are the daily values that allow people to relate one currency to another. **Ask** How could you know for certain which amount of money is worth more—75 euros or 75 British pounds? *(Convert these values to a familiar currency—U.S. dollars.)*

Activate Prior Knowledge

Provide various types of measuring devices to the class. Tell students to select one device and record the length of their shoe. Then ask them to create a chart and record the length of their shoe in inches, feet, yards, millimeters, centimeters, and meters. As a class, discuss how students determined the measurements. Begin a list of conversions on the word wall.

3.3 Solving Conversion Problems

CHEMISTRY & YOU

Q: *How can you convert U.S. dollars to euros?* Perhaps you have traveled to another country or are planning to do so. If so, you know (or will soon discover) that different countries have different currencies. As a tourist, exchanging money is an important part of having a good trip. After all, you often must use cash to pay for meals, transportation, and souvenirs. Because each country's currency compares differently with the U.S. dollar, knowing how to convert currency units correctly is essential. Conversion problems are readily solved by a problem-solving approach called dimensional analysis.

Key Questions

What happens when a measurement is multiplied by a conversion factor?

What kinds of problems can you solve using dimensional analysis?

Vocabulary

- conversion factor
- dimensional analysis

Conversion Factors

What happens when a measurement is multiplied by a conversion factor?

If you think about any number of everyday situations, you will realize that a quantity can usually be expressed in several different ways. For example, consider the monetary amount \$1.

1 dollar = 4 quarters = 10 dimes = 20 nickels = 100 pennies

These are all expressions, or measurements, of the same amount of money. The same thing is true of scientific quantities. For example, consider a distance that measures exactly 1 meter.

1 meter = 10 decimeters = 100 centimeters = 1000 millimeters

These are different ways to express the same length.

Whenever two measurements are equivalent, a ratio of the two meaurements will equal 1, or unity. For example, you can divide both sides of the equation 1 m = 100 cm by 1 m or by 100 cm.

$$\frac{1\text{m}}{1\text{m}} = \frac{100\text{ cm}}{1\text{ m}} = 1 \quad \text{or} \quad \frac{1\text{ m}}{100\text{ cm}} = \frac{100\text{ cm}}{100\text{ cm}} = 1$$

conversion factors

The ratios 100 cm/1 m and 1 m/100 cm are examples of conversion factors. A **conversion factor** is a ratio of equivalent measurements. The measurement in the numerator (on the top) is equivalent to the measurement in the denominator (on the bottom). The conversion factors shown above are read "one hundred centimeters per meter" and "one meter per hundred centimeters."

Focus on ELL

1 CONTENT AND LANGUAGE Present academic vocabulary for this lesson, such as *analyze*, *calculate*, and *evaluate*. Pronounce the words and have students repeat them. Provide explanations, examples, and visuals of each word so students are aware of what tasks lie ahead when they encounter these words.

2 FRONTLOAD THE LESSON Preview the conversion factors and Figure 3.12 in the text, and point out that conversion factors are fractions that contain both numbers and units of measurement. Briefly review the basics of working with fractions, including terminology and equivalent fractions.

3 COMPREHENSIBLE INPUT When writing problems on the board, assign a different color to each unique unit of measurement in the problem. This will assist students in understanding that a unit in the numerator can only be cancelled by an equivalent unit in the denominator.

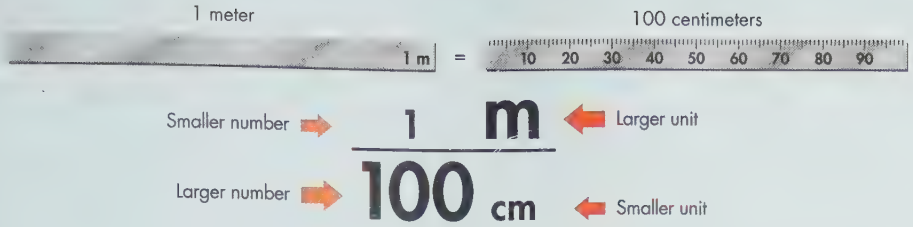


Figure 3.12 Conversion Factor
The two parts of a conversion factor, the numerator and the denominator, are equal.

See conversion factors animated online.

Figure 3.12 illustrates another way to look at the relationships in a conversion factor. Notice that the smaller number is part of the measurement with the larger unit. That is, a meter is physically larger than a centimeter. The larger number is part of the measurement with the smaller unit.

Conversion factors are useful in solving problems in which a given measurement must be expressed in some other unit of measure. **When a measurement is multiplied by a conversion factor, the numerical value is generally changed, but the actual size of the quantity measured remains the same.** For example, even though the numbers in the measurements 1 g and 10 dg (decigrams) differ, both measurements represent the same mass. In addition, conversion factors within a system of measurement are defined quantities or exact quantities. Therefore, they have an unlimited number of significant figures and do not affect the rounding of a calculated answer.

Here are some additional examples of pairs of conversion factors written from equivalent measurements. The relationship between grams and kilograms is 1000 g = 1 kg. The conversion factors are

$$\frac{1000\text{ g}}{1\text{ kg}} \quad \text{and} \quad \frac{1\text{ kg}}{1000\text{ g}}$$

Figure 3.13 shows a scale that can be used to measure mass in grams or kilograms. If you read the scale in terms of grams, you can convert the mass to kilograms by multiplying by the conversion factor 1 kg/1000 g.

The relationship between nanometers and meters is given by the equation 10^9 nm = 1 m. The possible conversion factors are

$$\frac{10^9\text{ nm}}{1\text{ m}} \quad \text{and} \quad \frac{1\text{ m}}{10^9\text{ nm}}$$

Common volumetric units used in chemistry include the liter and the microliter. The relationship 1 L = 10^6 μL yields the following conversion factors:

$$\frac{1\text{ L}}{10^6\ \mu\text{L}} \quad \text{and} \quad \frac{10^6\ \mu\text{L}}{1\text{ L}}$$

Based on what you have learned about metric prefixes, you should easily be able to write conversion factors that relate equivalent metric quantities.

Figure 3.13 Measuring Mass
This scale is calibrated to measure mass to the nearest 20 g.
Interpret Photos ***What is the scale showing in grams? In kilograms?***

Professional Development Note

Monetary Exchange Rates

The conversion of chemical units is similar to the exchange of currency. Americans who travel outside the United States must exchange U.S. dollars for foreign currency at a given rate of exchange. These exchange rates vary from day to day. The daily exchange rates affect all international monetary transactions. Each time one type of money is exchanged for another, the current exchange rate serves as a conversion factor. International currency traders keep track of exchange rates 24 hours a day through a linked computer network.

Foundations for Reading

BUILD VOCABULARY Have students write definitions of *conversion factor* and *dimensional analysis* in their own words. *(Sample answers: a ratio of equivalent measurements used to convert a quantity from one unit to another; a technique of problem-solving that uses the units that are part of a measurement to solve the problem.)*

Explain

Conversion Factors

USE VISUALS Have students inspect Figure 3.12. Emphasize that a conversion factor relates two equivalent measurements. **Ask** What two parts does every measurement have? *(a number and a unit)* Point out that if this is so, then every conversion factor must contain two numbers and two units so that one number and its unit equal another number and its unit.

Explore

Class Activity

PURPOSE Students will use dimensional analysis to convert common units.

MATERIALS copies of a recipe, lists of equivalents and conversions among the following measurements:

teaspoon, tablespoon, 1/4 cup, 1/2 cup, and 1 cup

(These lists are found in most cookbooks.)

PROCEDURE Distribute the recipe and the conversion list to pairs of students. Explain that they must rewrite the recipe so that it can feed six times the number of serving sizes suggested by the recipe. Point out that it would be tedious to have to measure out a particular ingredient (pick out one) in teaspoons or tablespoons six times, so students must rewrite the recipe in appropriately larger units. After students have rewritten the recipe, have student pairs exchange and compare recipes.

EXPECTED OUTCOME Students should use the conversion lists to write simple conversion factors, such as 3 teaspoons/1 tablespoon, and then rewrite the recipe using larger measurements.

Answers

FIGURE 3.13 The scale is showing 220 grams, or 0.22 kg.

LESSON 3.3

Explain

Dimensional Analysis

START A CONVERSATION Explain that dimensional analysis is an extremely powerful problem-solving tool. Learning this method requires extra effort on the part of students. They must often use multiple conversion factors. The extra effort can be justified because the proper manipulation of the units assures accurate manipulation of the numbers.

Emphasize that students should use dimensional analysis as a tool for solving all of the problems they encounter in chemistry. Their first question about any quantity should be, "What are the units of this quantity?" By comparing the units of various quantities in a problem, students can discover whether they need to perform any unit conversions before proceeding.

Sample Practice Problem

Mary worked 43,200 seconds this week. How many hours did Mary work this week? *(12 hours)*

Dimensional Analysis

What kinds of problems can you solve using dimensional analysis?

Some problems are best solved using algebra. For example, converting a kelvin temperature to Celsius can be done by using the equation °C = K − 273. Many problems in chemistry are conveniently solved using dimensional analysis. **Dimensional analysis** is a way to analyze and solve problems using the units, or dimensions, of the measurements. The best way to explain this technique is to use it to solve an everyday situation, as in Sample Problem 3.9.

As you read Sample Problem 3.10, you might see how the same problem could be solved algebraically but is more easily solved using dimensional analysis. In either case, you should choose the problem-solving method that works best for you. Try to be flexible in your approach to problem solving, as no single method is best for solving every type of problem.

SampleProblem 3.9

Using Dimensional Analysis

How many seconds are in a workday that lasts exactly eight hours?

1 Analyze **List the knowns and the unknown.**

To convert time in hours to time in seconds, you'll need two conversion factors. First you must convert hours to minutes: h ⟶ min. Then you must convert minutes to seconds: min ⟶ s. Identify the proper conversion factors based on the relationships 1 h = 60 min and 1 min = 60 s.

KNOWNS
time worked = 8 h
1 hour = 60 min
1 minute = 60 s

UNKNOWN
seconds worked = ? s

2 Calculate **Solve for the unknown.**

The first conversion factor is based on 1 h = 60 min. The unit hours must be in the denominator to cancel the known unit.

$\frac{60\ \text{min}}{1\ \text{h}}$

The second conversion factor is based on 1 min = 60 s. The unit minutes must be in the denominator so that the desired units (seconds) will be in your answer.

$\frac{60\ \text{s}}{1\ \text{min}}$

Before you do the actual arithmetic, it's a good idea to make sure that the units cancel and that the numerator and denominator of each conversion factor are equal to each other.

Multiply the time worked by the conversion factors.

$8\ \text{h} \times \frac{60\ \text{min}}{1\ \text{h}} \times \frac{60\ \text{s}}{1\ \text{min}} = 28{,}000\ \text{s} = 2.8800 \times 10^4\ \text{s}$

3 Evaluate **Does the result make sense?** The answer has the desired unit (s). Since the second is a small unit of time, you should expect a large number of seconds in 8 hours. The answer is exact since the given measurement and each of the conversion factors is exact.

36. How many minutes are there in exactly one week?

37. How many seconds are in an exactly 40-hour work week?

Foundations for Math

CONVERSION FACTORS Point out that a conversion factor is a ratio of equivalent *measurements*–that is, the numerator should contain both a number and a unit, and the denominator should contain both a number and a unit. For example, the relationship 60 minutes = 1 hour yields the following conversion factors:

$$\frac{60\ \text{minutes}}{1\ \text{hour}} \text{ and } \frac{1\ \text{hour}}{60\ \text{minutes}}$$

Knowing the unit of the given quantity and the desired unit of the answer dictates which conversion factor to use. To convert from hours to minutes, the denominator of the conversion factor must contain hours in order for the known unit to cancel, so you would use 60 min/1 h. Note that **Sample Problem 3.9** involves two conversions (from hours to minutes, and from minutes to seconds), each requiring its own conversion factor.

In **Sample Problem 3.9**, note that two such expressions are used, $\frac{60\ \text{minutes}}{1\ \text{hour}}$ and $\frac{60\ \text{seconds}}{1\ \text{minute}}$. This reflects the fact that for each equivalent relationship there are two possible conversion factors that can be written.

Sample Problem 3.10

Using Dimensional Analysis

The directions for an experiment ask each student to measure 1.84 g of copper (Cu) wire. The only copper wire available is a spool with a mass of 50.0 g. How many students can do the experiment before the copper runs out?

1 Analyze **List the knowns and the unknown.**

From the known mass of copper, use the appropriate conversion factor to calculate the number of students who can do the experiment. The desired conversion is mass of copper ⟶ number of students.

KNOWNS

mass of copper available = 50.0 g Cu

Each student needs 1.84 grams of copper.

UNKNOWN

number of students = ?

2 Calculate **Solve for the unknown.**

The experiment calls for 1.84 grams of copper per student. Based on this relationship, you can write the conversion factors:

$$\frac{1.84\ \text{g Cu}}{1\ \text{student}} \quad \text{and} \quad \frac{1\ \text{student}}{1.84\ \text{g Cu}}$$

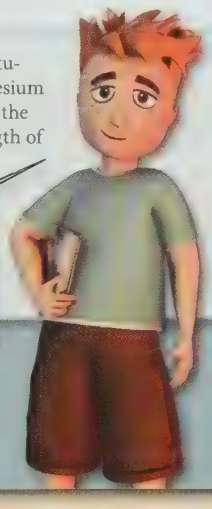
Because the desired unit for the answer is students, use the second conversion factor. Multiply the mass of copper by the conversion factor.

$$50.0\ \text{g Cu} \times \frac{1\ \text{student}}{1.84\ \text{g Cu}} = 27.174\ \text{students} = 27\ \text{students}$$

Note that because students cannot be fractional, the answer is rounded down to a whole number.

3 Evaluate **Does the result make sense?** The unit of the answer (students) is the one desired. You can make an approximate calculation using the following conversion factor.

$$\frac{1\ \text{student}}{2\ \text{g Cu}}$$



Multiplying the above conversion factor by 50 g Cu gives the approximate answer of 25 students, which is close to the calculated answer.

38. An experiment requires that each student use an 8.5-cm length of magnesium ribbon. How many students can do the experiment if there is a 570-cm length of magnesium ribbon available?

39. A 1.00-degree increase on the Celsius scale is equivalent to a 1.80-degree increase on the Fahrenheit scale. If a temperature increases by 48.0°C, what is the corresponding temperature increase in °F?

40. An atom of gold has a mass of 3.271×10^{-22} g. How many atoms of gold are in 5.00 g of gold?

Here's a tip: The equalities needed to write a particular conversion factor may be given in the problem. In other cases, you'll need to know or look up the necessary equalities.

Foundations for Math

ROUNDING Explain to students that some problems require a more logical rounding technique than using significant figures or decimal places. For example, money is typically rounded to the hundredths place because our money system includes pennies. The number of buses needed to transport a certain number of students on a field trip would be rounded UP to the next whole bus to make sure all students are accommodated. Have students think of other examples where rounding would not follow the conventional rules.

In **Sample Problem 3.10,** logically there is no such thing as 0.174 student, so the result of the calculation is rounded to a whole number. Explain that the number is rounded DOWN (unlike in the bus example above) because there is not enough copper for another student to do the experiment.

ADDRESS MISCONCEPTIONS Students may think that because a conversion factor equals unity, it does not matter whether the conversion factor or its reciprocal is used in a calculation. Remind students that a given pair of equivalent measurements yields two different conversion factors, only one of which can be used to obtain the correct conversion.

Sample Practice Problem

An experiment requires that each student use 8 grams of baking soda. If a full container of baking soda holds 340 grams, how many students can do the experiment? *(42 students)*

Answers

36. 1.0080×10^4 min
37. 1.44000×10^5 s
38. 67 students
39. 86.4°F
40. 1.53×10^{22} atoms

Explain

START A CONVERSATION Explain that measurements are often made using one unit and then converted into a related unit before being used in calculations. For example, students might measure volume in liters or milliliters in the laboratory, but express it as cubic centimeters in a calculation. Explain to the students that conversions are done using conversion factors. Emphasize that these conversion factors are ratios of *equivalent physical quantities,* such as 1 mL/1 cm^3.

MAKE A CONNECTION Reassure students that they are more familiar with conversions than they may realize. Point out examples of everyday conversions, such as converting money from cents to dollars and converting time from minutes to hours. Start out by giving them practice with everyday examples.
Ask A chicken needs to be cooked 20 minutes for each pound it weighs. How long should the chicken be cooked if it weighs 4.5 pounds? *(4.5 lb × 20 min/lb = 90 min; 90 min × 1 h/60 min = 1.5 h. Most students will automatically relate 90 minutes to 1.5 hours. This may help them become comfortable with the process.)* If students are having difficulty with conversion factors, provide a more tactile environment for students to discover these relationships.

Divide the class in half and have each group challenge the other to write the conversion factor given two related units. Remind them that each conversion factor can appear in two forms depending on which value they put in the numerator.

CHEMISTRY & YOU Sample answer (the conversion factor will vary with the exchange rate): \$50 × (€1/\$1.360) = €36.76

Sample Practice Problem

Make the following conversions.

a. 0.045 L to cubic centimeters *(4.5×10^1 cm^3)*
b. 14.3 mg to grams *(14.3×10^{-2} g)*
c. 0.0056 m to micrometers *(5.6×10^3 μm)*
d. 0.035 cm to millimeters *(3.5×10^{-1} mm)*

CHEMISTRY & YOU

Q: *Look up the exchange rate between U.S. dollars and euros on the Internet. Write a conversion factor that allows you to convert from U.S. dollars to euros. How many euros could you buy with \$50?*

Simple Unit Conversions In chemistry, as in everyday life, you often need to express a measurement in a unit different from the one given or measured initially. **Dimensional analysis is a powerful tool for solving conversion problems in which a measurement with one unit is changed to an equivalent measurement with another unit.** Sample Problems 3.11 and 3.12 walk you through how to solve simple conversion problems using dimensional analysis.

SampleProblem 3.11

Converting Between Metric Units

Express 750 dg in grams. (Refer to Table 3.2 if you need to refresh your memory of metric prefixes.)

1 Analyze **List the knowns and the unknown.**
The desired conversion is decigrams ⟶ grams. Multiply the given mass by the proper conversion factor.

KNOWNS: mass = 750 dg; 1 g = 10 dg
UNKNOWN: mass = ? g

2 Calculate **Solve for the unknown.**

Use the relationship 1 g = 10 dg to write the correct conversion factor. → $\frac{1\ g}{10\ dg}$

Multiply the known mass by the conversion factor. → $750\ dg \times \frac{1\ g}{10\ dg} = 75\ g$

Note that the known unit (dg) is in the denominator and the unknown unit (g) is in the numerator.

3 Evaluate **Does the result make sense?** Because the unit gram represents a larger mass than the unit decigram, it makes sense that the number of grams is less than the given number of decigrams. The answer has the correct unit (dg) and the correct number of significant figures.

41. Using tables from this chapter, convert the following:
a. 0.044 km to meters
b. 4.6 mg to grams
c. 0.107 g to centigrams

42. Convert the following:
a. 15 cm^3 to liters
b. 7.38 g to kilograms
c. 6.7 s to milliseconds
d. 94.5 g to micrograms

Foundations for Math

MORE ON METRIC CONVERSIONS Explain to students that it is possible to convert "through" the basic metric unit in order to quickly go from very large units to very small units or vice versa. This requires more than one conversion factor in the dimensional analysis calculation, each of which involves the basic metric unit. Demonstrate this example: How many centigrams are there in 0.8 kilograms?

$$0.8\ kg \times \frac{1000\ g}{1\ kg} \times \frac{100\ cg}{1\ g} = 80{,}000\ cg$$

Point out that the desired unit (cg) is placed in the numerator of the last conversion factor. In **Sample Problem 3.11**, point out that the initial unit is placed in the denominator of the conversion factor and the desired unit is placed in the numerator.

Sample Problem 3.12

Using Density as a Conversion Factor

What is the volume of a pure silver coin that has a mass of 14 g? The density of silver (Ag) is 10.5 g/cm³.

1 Analyze **List the knowns and the unknown.**

You need to convert the mass of the coin into a corresponding volume. The density gives you the following relationship between volume and mass: 1 cm^3 Ag = 10.5 g Ag. Multiply the given mass by the proper conversion factor to yield an answer in cm^3.

KNOWNS
mass = 14 g
density of silver = 10.5 g/cm^3

UNKNOWN
volume of coin = ? cm^3

2 Calculate **Solve for the unknown.**

Use the relationship 1 cm^3 Ag = 10.5 g Ag to write the correct conversion factor.

$$\frac{1\ cm^3\ Ag}{10.5\ g\ Ag}$$

Notice that the known unit (g) is in the denominator and the unknown unit (cm^3) is in the numerator.

Multiply the mass of the coin by the conversion factor.

$$14\ \cancel{g\ Ag} \times \frac{1\ cm^3\ Ag}{10.5\ \cancel{g\ Ag}} = 1.3\ cm^3\ Ag$$

3 Evaluate **Does the result make sense?** Because a mass of 10.5 g of silver has a volume of 1 cm^3, it makes sense that 14.0 g of silver should have a volume slightly larger than 1 cm^3. The answer has two significant figures because the given mass has two significant figures.

43. Use dimensional analysis and the given densities to make the following conversions:
- **a.** 14.8 g of boron to cm^3 of boron. The density of boron is 2.34 g/cm^3.
- **b.** 4.62 g of mercury to cm^3 of mercury. The density of mercury is 13.5 g/cm^3.

44. Rework the preceding problems by applying the following equation:

$$\text{Density} = \frac{\text{mass}}{\text{volume}}$$

45. What is the mass, in grams, of a sample of cough syrup that has a volume of 50.0 cm^3? The density of cough syrup is 0.950 g/cm^3.

Differentiated Instruction

ELL ENGLISH LANGUAGE LEARNERS Provide as much class time as possible for students to work on problem assignments in cooperative learning groups of varying proficiencies. Encourage students with high proficiency to assist students with lower proficiencies by reading the problem out loud.

LPR LESS PROFICIENT READERS Students may benefit from a reminder that certain key words and phrases in each word problem indicate the unknown quantity and its units. Some of these phrases are: *how much*, *what is*, *how long*, *determine*, and *find*.

L3 ADVANCED STUDENTS Direct students' attention to Tables 3.3, 3.4, and 3.5 in Lesson 3.2. Have students express the ratio in scientific notation between the largest and smallest units listed in each table. *(Table 3.3: 1 × 10^{12}; Table 3.4: 1 × 10^6; Table 3.5: 1 × 10^9)*

Explore

Class Activity

PURPOSE Students will use dimensional analysis to convert between English and metric units.

MATERIALS Internet access or copies of media guides containing vital statistics, such as heights and weights, of players on a sports team (These guides are available from local sports franchises.)

PROCEDURE Distribute the media guides and assign each group of students a set of players. Ask the group to convert heights and weights into heights and masses expressed in meters and kilograms, respectively. Have students document their approach, including dimensional analysis expressions, conversion factors, and calculations.

EXPECTED OUTCOMES Students should use conversion factors, such as 2.54 cm/1 inch and 454 g/1 lb, to convert their measurements.

Sample Practice Problem

The density of mineral oil is 0.835 g/cm^3. What is the mass in grams of a sample of mineral oil that has a volume of 2.50 cm^3? *(2.09 grams)*

Answers

41. **a.** 44 m
b. 4.6×10^{-3} g
c. 10.7 cg
42. **a.** 1.5×10^{-2} L
b. 7.38×10^{-3} kg
c. 6.7×10^{3} ms
d. 9.45×10^{7} µg
43. **a.** 6.32 cm^3 **b.** 0.342 cm^3
44. See answers for Problem 43.
45. 47.5 g

Explain

Sample Practice Problem

How many deciliters are in 6.5 hectoliters?
(6,500 deciliters)

Multistep Problems Many complex tasks in your life are best handled by breaking them down into smaller, manageable parts. For example, if you were cleaning a car, you might first vacuum the inside, then wash the exterior, then dry the exterior, and finally put on a fresh coat of wax. Similarly, many complex word problems are more easily solved by breaking the solution down into steps.

When converting between units, it is often necessary to use more than one conversion factor. Sample Problems 3.13 and 3.14 illustrate the use of multiple conversion factors.

SampleProblem 3.13

Converting Between Metric Units

The diameter of a sewing needle is 0.073 cm. What is the diameter in micrometers?

1 Analyze **List the knowns and the unknown.**

The desired conversion is centimeters ⟶ micrometers. The problem can be solved in a two-step conversion. First change centimeters to meters; then change meters to micrometers: centimeters ⟶ meters ⟶ micrometers.

KNOWNS

length = 0.073 cm = 7.3×10^{-2} cm

10^2 cm = 1 m

1 m = 10^6 μm

UNKNOWN

length = ? μm

2 Calculate **Solve for the unknown.**

Use the relationship 10^2 cm = 1 m to write the first conversion factor.

$$\frac{1\text{ m}}{10^2\text{ cm}}$$

Use the relationship 1 m = 10^6 μm to write the second conversion factor.

$$\frac{10^6\ \mu\text{m}}{1\text{ m}}$$

Each conversion factor is written so that the unit in the denominator cancels the unit in the numerator of the previous factor.

Multiply the known length by the conversion factors.

$$7.3 \times 10^{-2}\ \text{cm} \times \frac{1\ \text{m}}{10^2\ \text{cm}} \times \frac{10^6\ \mu\text{m}}{1\ \text{m}} = 7.3 \times 10^2\ \mu\text{m}$$

3 Evaluate **Does the result make sense?** Because a micrometer is a much smaller unit than a centimeter, the answer should be numerically larger than the given measurement. The units have canceled correctly, and the answer has the correct number of significant figures.

46. The radius of a potassium atom is 0.227 nm. Express this radius in the unit centimeters.

47. The diameter of Earth is 1.3×10^4 km. What is the diameter expressed in decimeters?

Focus on ELL

4 LANGUAGE PRODUCTION Have students work in pairs to complete the Small-Scale Lab on page 92. Make sure each pair has ELLs of varied language proficiencies, so that more proficient students can help less proficient ones. Have students work according to their proficiency level.

BEGINNING: LOW/HIGH Provide students a detailed step-by-step procedure to follow using pictures, words, and symbols. Be sure to show a balance with a question mark on top of it to indicate that students are to find the mass. Convey that the same procedure is to be followed three times.

INTERMEDIATE: LOW/HIGH Have accelerated students perform the procedure for finding the mass of a drop of water using verbal questioning of what to do next. Have students mimic this procedure for finding the mass of the pre-1982 penny and the post-1892 penny.

ADVANCED: LOW/HIGH Have students read out loud the questions in the Analyze and You're the Chemist sections. Then assist and/or edit the work of classmates with lower language proficiency.

Sample Problem 3.14

Converting Ratios of Units

The density of manganese, a metal, is 7.21 g/cm^3. What is the density of manganese expressed in units of kg/m^3?

1 Analyze **List the knowns and the unknown.**

The desired conversion is g/cm^3 ⟶ kg/m^3. The mass unit in the numerator must be changed from grams to kilograms: g ⟶ kg. In the denominator, the volume unit must be changed from cubic centimeters to cubic meters: cm^3 ⟶ m^3. Note that the relationship 10^6 cm^3 = 1 m^3 was derived by cubing the relationship 10^2 cm = 1 m. That is, $(10^2 \text{ cm})^3 = (1 \text{ m})^3$, or 10^6 cm^3 = 1 m^3.

KNOWNS

density of manganese = 7.21 g/cm^3
10^3 g = 1 kg
10^6 cm^3 = 1 m^3

UNKNOWN

density of manganese = ? kg/m^3

2 Calculate **Solve for the unknown.**

Multiply the known density by the correct conversion factors.

$$\frac{7.21 \text{ g}}{1 \text{ cm}^3} \times \frac{1 \text{ kg}}{10^3 \text{ g}} \times \frac{10^6 \text{ cm}^3}{1 \text{ m}^3} = 7.21 \times 10^3 \text{ kg/m}^3$$

3 Evaluate **Does the result make sense?**

Because the physical size of the volume unit m^3 is so much larger than cm^3 (10^6 times), the calculated value of the density should be larger than the given value even though the mass unit is also larger (10^3 times). The units cancel, the conversion factors are correct, and the answer has the correct ratio of units.

48. Gold has a density of 19.3 g/cm^3. What is the density in kilograms per cubic meter?

49. There are 7.0×10^6 red blood cells (RBCs) in 1.0 mm^3 of blood. How many red blood cells are in 1.0 L of blood?

3.3 LessonCheck

50. **Review** What happens to the numerical value of a measurement that is multiplied by a conversion factor? What happens to the actual size of the quantity?

51. **Review** What types of problems can be solved using dimensional analysis?

52. **Identify** What conversion factor would you use to convert between these pairs of units?
- **a.** minutes to hours
- **b.** grams to milligrams
- **c.** cubic decimeters to milliliters

53. **Calculate** Make the following conversions. Express your answers in scientific notation.
- **a.** 14.8 g = ? µg
- **b.** 3.72 g = ? kg
- **c.** 66.3 L = ? cm^3
- **d.** 7.5×10^4 J = ? kJ
- **e.** 3.9×10^5 mg = ? dg
- **f.** 2.1×10^{-4} dL = ? µL

54. **Calculate** What is the mass, in kilograms, of 14.0 L of gasoline? (Assume that the density of gasoline is 0.680 g/cm^3.)

55. **Apply Concepts** Light travels at a speed of 3.00×10^{10} cm/s. What is the speed of light in kilometers/hour?

Lesson Check Answers

50. The numerical value (and the unit) changes; the actual size does not change.

51. conversion problems

52. **a.** 1 hour / 60 min
b. 10^3 mg / 1 g
c. 10^3 mL / 1 dm^3

53. **a.** 1.48×10^7 µg
b. 3.72×10^{-3} kg
c. 6.63×10^4 cm^3
d. 7.5×10^1 kJ
e. 3.9×10^3 dg
f. 2.21×10^1 µL

54. 9.52 kg

55. 1.08×10^9 km/h

Explain

Sample Practice Problem

In physics, acceleration is usually given in units of m/s^2. The acceleration of a falling object due to gravity is 9.8 m/s^2. What is the acceleration due to gravity in km/min^2? (*35.28 km/min^2*)

Evaluate

Informal Assessment

To determine students' grasp of conversion factors, ask students to orally explain the relationship between the numerator and the denominator of any measurement conversion factor. *(They are equivalent so that the ratio of numerator to denominator equals 1.)* Then have students complete the 3.3 Lesson Check.

Reteach

Model the conversion of 2 L to 2000 mL. Suggest that students check the answer by explaining that when using a conversion factor, such as 1 L = 1000 mL, the measurement expressed with the smaller unit (mL) should have a larger number associated with it than the measurement expressed with the larger unit (L).

Answers

46. 2.27×10^{-8} cm
47. 1.3×10^8 dm
48. 1.93×10^4 kg/m^3
49. 7.0×10^{12} RBC/L

Small-Scale Lab

OBJECTIVE After completing this activity, students will be able to solve problems in divergent ways.

SKILLS FOCUS measuring, calculating, evaluating, designing experiments

PREP TIME 1 hour

MATERIALS Calculators, small-scale pipets, meter sticks, water, mass balances, pre- and post-1982 pennies, dice, 8-well strips, aluminum cans, plastic cups

ADVANCE PREP A day before doing the lab, obtain soda cans from the cafeteria. Wash and let air-dry overnight.

CLASS TIME 40 minutes

EXPECTED OUTCOME Students should find that the mass of the pre-1982 penny is 3.11 g and the mass of the post-1982 penny is 2.50 g.

ANALYZE

1. 19 mg
2. 0.019 cm^3; 0.019 mL; 19 µL
3. 1000 mg/cm^3; 1000 mg/mL
4. 2.95 g Cu; 0.16 g Zn
5. 0.060 g Cu; 2.44 g Zn
6. The new penny is mostly zinc, which has a lower density than copper.

YOU'RE THE CHEMIST

1. at 90°, mass of 1 drop: 0.019 g
   at 45°, mass of 1 drop: 0.0218 g
   at 0°, mass of 1 drop: 0.0242 g
   Pipets give different results.
2. The pipet is easiest to control at 90°. Expel the air bubble so that the first drop will be the same size as the rest.
3. Find the mass of the can and divide by the density of aluminum. Sample answer: mass of one can: 14.77 g; density of Al: 2.70 g/cm^3; V = 5.47 cm^3
4. (1) Measure the mass before and after you fill the can with water. Use the mass and density of water to find the volume.
   (2) Measure the height and radius and calculate volume. $V = \pi r^2 h$ (Can is not a perfect cylinder.)
   (3) Read label: 12 oz = 355 mL
5. Sample answer:
   V = 16.5 m × 3.0 m × 12.8 m = 630 m^3 × 1000 L/m^3 = 630,000 L. Assume 30 people with an average weight of 130 lb (1 kg = 2.2 lb) and a density of about 1.0 kg/L. Volume of 30 people = 30 × 130 lb × 1 kg/2.2 lb × 1 L/1.0 kg = 1800 L. The volume of 30 chairs, 15 tables, and 2 desks is about that of 30 people or 1800 L. The volume of people and furniture is 3600 L. % error = (3600 L/630,000 L)(100%) = 0.57%.

Small-Scale Lab

Now What Do I Do?

Purpose

To solve problems by making accurate measurements and applying mathematics

Materials

- pencil
- paper
- meter stick
- balance
- pair of dice
- aluminum can
- calculator
- small-scale pipet
- water
- a pre-1982 penny
- a post-1982 penny
- 8-well strip
- plastic cup

Procedure

1. Determine the mass, in grams, of one drop of water. To do this, measure the mass of an empty cup. Add 50 drops of water from a small-scale pipet to the cup and measure its mass again. Subtract the mass of the empty cup from the mass of the cup with water in it. To determine the average mass in grams of a single drop, divide the mass of the water by the number of drops (50). Repeat this experiment until your results are consistent.

2. Determine the mass of a pre-1982 penny and a post-1982 penny.

Analyze

Using your experimental data, record the answers to the following questions.

1. Calculate What is the average mass of a single drop of water in milligrams? (1 g = 1000 mg)

2. Calculate The density of water is 1.00 g/cm^3. Calculate the volume of a single drop in cm^3 and mL. (1 mL = 1 cm^3) What is the volume of a drop in microliters (µL)? (1000 µL = 1 mL)

3. Calculate What is the density of water in units of mg/cm^3 and mg/mL? (1 g = 1000 mg)

4. Calculate Pennies made before 1982 consist of 95.0% copper and 5.0% zinc. Calculate the mass of copper and the mass of zinc in the pre-1982 penny.

5. Calculate Pennies made after 1982 are made of zinc with a thin copper coating. They are 97.6% zinc and 2.4% copper. Calculate the mass of copper and the mass of zinc in the newer penny.

6. Explain Why does one penny have less mass than the other?

You're the Chemist

The following small-scale activities allow you to develop your own procedures and analyze the results.

1. Design an Experiment Design an experiment to determine if the size of drops varies with the angle at which they are delivered from the pipet. Try vertical (90°), horizontal (0°), and halfway between (45°). Repeat until your results are consistent.

2. Analyze Data What is the best angle to hold a pipet for ease of use and consistency of measurement? Explain. Why is it important to expel the air bubbles before you begin the experiment?

3. Design an Experiment Make the necessary measurements to determine the volume of aluminum used to make an aluminum soda can. *Hint:* Look up the density of aluminum in your textbook.

4. Design an Experiment Design and carry out some experiments to determine the volume of liquid that an aluminum soda can will hold.

5. Design an Experiment Measure a room and calculate the volume of air it contains. Estimate the percent error associated with not taking into account the furniture in the room.

6. Design an Experiment Make the necessary measurements and do the necessary calculations to determine the volume of a pair of dice. First, ignore the volume of the dots on each face, and then account for the volume of the dots. What is your error and percent error when you ignore the holes?

6. If die measures 1.55 cm on a side:
   $V = (1.55\ cm)^3 = 3.72\ cm^3$
   A die has 21 holes that are hemispheres with a radius of 0.20 cm.
   V of hemisphere = $(2/3)\pi r^3 = 0.017\ cm^3$
   V of 21 hemispheres = $0.36\ cm^3$
   V of die = $3.72\ cm^3 - 0.36\ cm^3 = 3.36\ cm^3$
   Error = $0.36\ cm^3$
   % error = $(0.36\ cm^3/3.36\ cm^3)(100\%) = 11\%$

3 Study Guide

BIG IDEA QUANTIFYING MATTER

Scientists express the degree of uncertainty in their measurements and calculations by using significant figures. In general, a calculated answer cannot be more precise than the least precise measurement from which it was calculated. Dimensional analysis is a problem-solving method that involves analyzing the units of the given measurement and the unknown to plan a solution.

3.1 Using and Expressing Measurements

- In scientific notation, the coefficient is always a number greater than or equal to one and less than ten. The exponent is an integer.
- To evaluate accuracy, the measured value must be compared to the correct value. To evaluate the precision of a measurement, you must compare the values of two or more repeated measurements.
- Measurements must always be reported to the correct number of significant figures because calculated answers often depend on the number of significant figures in the values used in the calculation.

- measurement (62)
- scientific notation (62)
- accuracy (64)
- precision (64)
- accepted value (65)
- experimental value (65)
- error (65)
- percent error (65)
- significant figures (66)

Key Equations

$$\text{Error} = \text{experimental value} - \text{accepted value}$$

$$\text{Percent error} = \frac{\text{error}}{\text{accepted value}} \times 100\%$$

3.2 Units of Measurement

- All metric units are based on multiples of 10. As a result, you can convert between units easily.
- Scientists commonly use two equivalent units of temperature, the degree Celsius and the kelvin.
- Density is an intensive property that depends only on the composition of a substance.

- International System of Units (SI) (74)
- meter (m) (75)
- liter (L) (76)
- kilogram (kg) (77)
- gram (g) (77)
- weight (77)
- energy (77)
- joule (J) (77)
- calorie (cal) (77)
- temperature (78)
- Celsius scale (78)
- Kelvin scale (78)
- absolute zero (79)
- density (80)

Key Equations

$$K = {}^\circ C + 273 \qquad {}^\circ C = K - 273$$

$$\text{Density} = \frac{\text{mass}}{\text{volume}}$$

3.3 Solving Conversion Problems

- When a measurement is multiplied by a conversion factor, the numerical value is generally changed, but the actual size of the quantity measured remains the same.
- Dimensional analysis is a powerful tool for solving conversion problems in which a measurement with one unit is changed to an equivalent measurement with another unit.

- conversion factor (84)
- dimensional analysis (86)

Focus on ELL

5 ASSESS UNDERSTANDING Have students keep a content area log. Consider using a two column format with the headings *What I understand* and *What I do not understand*. Follow up with students on the items in the *What I do not understand* column.

BEGINNING

LOW Give students a list of examples, vocabulary, and concepts with boxes that they can check for *understand* or *do not understand*.

HIGH Students can copy vocabulary, sample problem numbers, and key questions into either column of the chart.

INTERMEDIATE: LOW/HIGH Ask students to specify the step(s) in the sample problems that they do not understand.

ADVANCED: LOW/HIGH Ask students to review the content area logs of those students with lower proficiencies. If there is an area that they understand but another student does not, encourage them to reteach the concept to that student.

Evaluate

Review and Assessment Materials

WALK-THRU TUTORIALS Each of the Sample Problems displaying the Chem Tutor icon has an online animated step-by-step tutorial that explains the problem-solving strategy in detail.

PROBLEM SETS Have students practice more scientific measurement problems using the Chapter 3 Online Problem Set.

MATH SKILLS REVIEW Have struggling students practice solving algebraic equations using the MathXL learning module.

Study Tip

CHOOSE A QUIET PLACE Tell students that being able to concentrate while studying will increase their comprehension. Therefore, a quiet place where they will not be distracted can help them achieve a better grasp of the subject material and will make their study time more efficient.

Math Tune-Up: Conversion Problems

Problem	❶ Analyze	❷ Calculate	❸ Evaluate
A grocer is selling oranges at 3 for \$2. How much would it cost to buy a dozen oranges?	Knowns: 3 oranges = \$2 1 dozen = 12 Unknown: Cost of 12 oranges = ? The desired conversion is oranges ⟶ \$.	Use the relationship 3 oranges = \$2 to write the correct conversion factor. $\frac{\$2}{3 \text{ oranges}}$ Multiply the known quantity by the conversion factor. $12 \text{ oranges} \times \frac{\$2}{3 \text{ oranges}} = \$8$	A dozen is larger than the number 3, so the cost should exceed \$2. The known unit (oranges) cancels, and the answer has the correct unit (\$).
Convert the volume 865 cm^3 to liters.	Knowns: volume = 865 cm^3 10^3 cm^3 = 1 L Unknown: volume = ? L The desired conversion is cm^3 ⟶ L.	Use the relationship 10^3 cm^3 = 1 L to write the correct conversion factor. $\frac{1 \text{ L}}{10^3 \text{ cm}^3}$ Multiply the known volume by the conversion factor. $865 \text{ cm}^3 \times \frac{1 \text{ L}}{10^3 \text{ cm}^3} = 0.865 \text{ L}$	A cubic centimeter is much smaller than a liter, so the answer should be numerically smaller than the given measurement. The known unit (cm^3) cancels, and the answer has the correct unit (L).
Express the length 8.2×10^{-4} μm in centimeters.	Knowns: length = 8.2×10^{-4} μm 10^6 μm = 1 m 1 m = 10^2 cm Unknown: length = ? L The desired conversion is μm ⟶ cm. First change μm to m; then change m to cm: μm ⟶ m ⟶ cm	Use the relationship 10^6 μm = 1 m to write the first conversion factor. $\frac{1 \text{ m}}{10^6 \text{ μm}}$ Use the relationship 1 m = 10^2 cm to write the second conversion factor. $\frac{10^2 \text{ cm}}{1 \text{ m}}$ Multiply the known length by the conversion factors. $8.2 \times 10^{-4} \text{ μm} \times \frac{1 \text{ m}}{10^6 \text{ μm}} \times \frac{10^2 \text{ cm}}{1 \text{ m}}$ $= 8.2 \times 10^{-8} \text{ cm}$	A micrometer is smaller than a centimeter, so the answer should be numerically smaller than the given measurement. The known unit (μm) cancels, and the answer has the correct unit (cm). *Hint: For a multistep problem, take it one conversion at a time.*

UbD Performance Tasks

OUTER SPACE Develop an original way to show the advantages and disadvantages of NASA eliminating the need for uncertainty in measurements.

SCALE MODELING Create a three-dimensional model to physically show the relationship between the prefixes given in Table 3.2 to scale. Present the model to the class.

3 Assessment

* Solutions appear in Appendix E

Lesson by Lesson

3.1 Using and Expressing Measurements

56. Three students made multiple weighings of a copper cylinder, each using a different balance. Describe the accuracy and precision of each student's measurements if the correct mass of the cylinder is 47.32 g.

Mass of Cylinder (g)			
	Colin	Lamont	Kivrin
Weighing 1	47.13	47.45	47.95
Weighing 2	47.94	47.39	47.91
Weighing 3	46.83	47.42	47.89
Weighing 4	47.47	47.41	47.93

57. How many significant figures are in each underlined measurement?

a. 60 s = 1 min
b. 47.70 g of copper
c. 1 km = 1000 m
d. 25 computers
e. 9 innings in a baseball game
f. 0.0950 m of gold chain

58. Round off each of these measurements to three significant figures.

a. 98.473 L
b. 0.000 763 21 cg
c. 57.048 m
d. 12.17°C
e. $0.007\,498\,3 \times 10^4$ mm
f. 1764.9 mL

***59.** Round off each of the answers correctly.

a. 8.7 g + 15.43 g + 19 g = 43.13 g
b. 4.32 cm × 1.7 cm = 7.344 cm^2
c. 853.2 L − 627.443 L = 225.757 L
d. 38.742 m^2 ÷ 0.421 m = 92.023 75 m
e. 5.40 m × 3.21 m × 1.871 m = 32.431 914 m^3
f. 5.47 m^3 + 11 m^3 + 87.300 m^3 = 103.770 m^3

***60.** Express each of the rounded-off answers in Problems 58 and 59 in scientific notation.

61. How are the *error* and the *percent* error of a measurement calculated?

3.2 Units of Measurement

62. Write the SI base unit of measurement for each of these quantities.

a. time
b. length
c. temperature
d. mass
e. energy
f. amount of substance

***63.** Order these units from smallest to largest: cm, µm, km, mm, m, nm, dm, pm. Then give each measurement in terms of meters.

64. Measure each of the following dimensions using a unit with the appropriate prefix.

a. the height of this letter I
b. the width of Table 3.3
c. the height of this page

65. State the relationship between degrees Celsius and kelvins.

***66.** The melting point of silver is 962°C. Express this temperature in kelvins.

67. What equation is used to determine the density of an object?

68. Would the density of a person be the same on the surface of Earth and on the surface of the moon? Explain.

***69.** A shiny, gold-colored bar of metal weighing 57.3 g has a volume of 4.7 cm^3. Is the bar of metal pure gold?

70. Three balloons filled with neon, carbon dioxide, and hydrogen are released into the atmosphere. Using the data in Table 3.6 on page 81, describe the movement of each balloon.

3.3 Solving Conversion Problems

71. What is the name given to a ratio of two equivalent measurements?

72. What must be true for a ratio of two measurements to be a conversion factor?

73. How do you know which unit of a conversion factor must be in the denominator?

Evaluate

Answers

LESSON 3.1

56. Colin: inaccurate and imprecise; Lamont: accurate and precise; Kivrin: inaccurate and precise

57. **a.** infinite **b.** 4 **c.** infinite **d.** infinite **e.** infinite **f.** 3

58. **a.** 98.5 L **b.** 0.000 763 cg **c.** 57.0 m **d.** 12.2°C **e.** 0.00750×10^4 mm **f.** 1760 mL

59. **a.** 43 g **b.** 7.3 cm^2 **c.** 225.8 L **d.** 92.0 m **e.** 32.4 m^3 **f.** 104 m^3

60. (58) **a.** 9.85×10^1 L **b.** 7.63×10^{-4} cg **c.** 5.70×10^1 m **d.** 1.22×10^1°C **e.** 7.50×10^{-3} mm **f.** 1.76×10^3 mL; (59) **a.** 4.3×10^1 g **b.** 7.3×10^0 cm^2 **c.** 2.258×10^2 L **d.** 9.20×10^1 m **e.** 3.24×10^1 m^3 **f.** 104×10^2 m^3

61. The error is the difference between the experimental value and the accepted value. The percent error is the error divided by the accepted value multiplied by 100.

LESSON 3.2

62. **a.** second **b.** meter **c.** kelvin **d.** kilogram **e.** joule **f.** mole

63. pm, nm, µm, mm, cm, dm, m, km; 1 km = 10^3 m, 1 dm = 10^{-1} m, 1 cm = 10^{-2} m, 1 mm = 10^{-3} m, 1 µm = 10^{-6} m, 1 nm = 10^{-9} m, 1 pm = 10^{-12} m

64. **a.** 2.4 mm **b.** 14.10 cm **c.** 29.32 cm

65. Degrees Celsius equals kelvins minus 273.

66. 1235 K

67. density = mass/volume

68. Yes; neither mass nor volume of a solid or liquid changes appreciably with location.

69. No; the density of the metal bar is 12 g/cm^3, but the density of gold is 19 g/cm^3.

70. The carbon dioxide–filled balloon would sink. The neon and hydrogen-filled balloons would rise, the hydrogen-filled ones at a much faster rate.

LESSON 3.3

71. conversion factor

72. They must equal one another.

73. The unit of the conversion factor in the denominator must be identical to the unit in the given measurement or the previous conversion factor.

ASSESSMENT

Evaluate

Answers

74. **a.** 1.57 s **b.** 4.27×10^4 mL **c.** 2.61×10^{-4} mm **d.** 6.5×10^2 dm **e.** 6.42×10^{-3} kg **f.** 8.25×10^9 ng

75. **a.** 7.3 μL/s **b.** 78.6 mg/mm^2 **c.** 1.54 g/cm^3

76. 10^6 mL

77. **a.** 2.83×10^2 mg **b.** 0.283 g **c.** 2.83×10^{-4} kg **d.** 6.6 g **e.** 6.6×10^2 cg **f.** 6.6×10^{-3} kg **g.** 2.8×10^{-1} mg **h.** 2.8×10^{-2} cg **i.** 2.8×10^{-7} kg

UNDERSTAND CONCEPTS

78. improper calibration or improper use of the measuring device

79. e, d, c, f, a, b

80. **a.** accurate and precise **b.** inaccurate and precise **c.** inaccurate and imprecise

81. °F = 1.8°C + 32

82. germanium

83. 0.69–0.789 g/cm^3

84. Sink; the ball's density is 0.802 g/cm^3, which is greater than the density of gasoline (0.66–0.69 g/cm^3, Table 3.6).

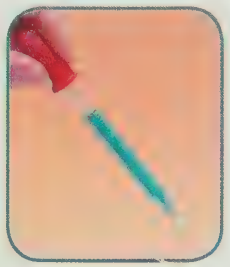
85. 1 g/10^2 cg, 10^2 cg/1 g, 1 g/10^3 mg, 10^3 mg/1 g, 10^2 cg/10^3 mg, 10^3 mg/10^2 cg

86. 81.3 kg

87. 4.20×10^4 cm^3

88. 73 g

89. 0.804 g/cm^3



90. 3.6 min lost

91. 0.92 kg/L

*74. Make the following conversions:
- a. 157 cs to seconds
- b. 42.7 L to milliliters
- c. 261 nm to millimeters
- d. 0.065 km to decimeters
- e. 642 cg to kilograms
- f. 8.25×10^2 cg to nanograms

*75. Make the following conversions:
- a. 0.44 mL/min to microliters per second
- b. 7.86 g/cm^2 to milligrams per square millimeter
- c. 1.54 kg/L to grams per cubic centimeter

76. How many milliliters are contained in 1 m^3?

*77. Complete this table so that all the measurements in each row have the same value.

mg	g	cg	kg
a. ____	b. ____	28.3	c. ____
6.6×10^3	d. ____	e. ____	f. ____
g. ____	2.8×10^{-4}	h. ____	i. ____

Understand Concepts

78. List two possible reasons for reporting precise, but inaccurate, measurements.

79. Rank these numbers from smallest to largest.
- a. 5.3×10^4
- b. 57×10^3
- c. 4.9×10^{-2}
- d. 0.0057
- e. 5.1×10^{-3}
- f. 0.0072×10^2

80. Comment on the accuracy and precision of these basketball free-throw shooters.
- a. 99 of 100 shots are made.
- b. 99 of 100 shots hit the front of the rim and bounce off.
- c. 33 of 100 shots are made; the rest miss.

81. Fahrenheit is a third temperature scale. Plot the data in the table and use the graph to derive an equation for the relationship between the Fahrenheit and Celsius temperature scales.

Example	°C	°F
Melting point of selenium	221	430
Boiling point of water	100	212
Normal body temperature	37	98.6
Freezing point of water	0	32
Boiling point of chlorine	−34.6	−30.2

82. Which would melt first, germanium with a melting point of 1210 K or gold with a melting point of 1064°C?

83. A piece of wood sinks in ethanol but floats in gasoline. Give a range of possible densities for the wood.

84. A plastic ball with a volume of 19.7 cm^3 has a mass of 15.8 g. Would this ball sink or float in a container of gasoline?

85. Write six conversion factors involving these units of measure: 1 g = 10^2 cg = 10^3 mg.

*86. A 2.00-kg sample of bituminous coal is composed of 1.30 kg of carbon, 0.20 kg of ash, 0.15 kg of water, and 0.35 kg of volatile (gas-forming) material. Using this information, determine how many kilograms of carbon are in 125 kg of this coal.

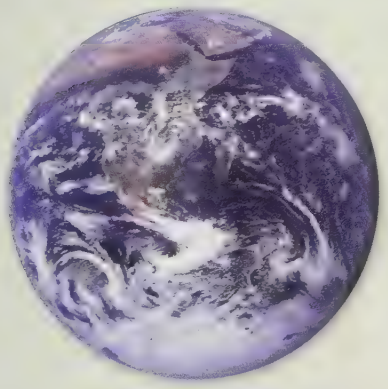
*87. The density of dry air measured at 25°C is 1.19×10^{-3} g/cm^3. What is the volume of 50.0 g of air?

88. What is the mass of a cube of aluminum that is 3.0 cm on each edge? The density of aluminum is 2.7 g/cm^3.

*89. A flask that can hold 158 g of water at 4°C can hold only 127 g of ethanol at the same temperature. What is the density of ethanol?

*90. A watch loses 0.15 s every minute. How many minutes will the watch lose in 1 day?

*91. A tank measuring 28.6 cm by 73.0 mm by 0.72 m is filled with olive oil. The oil in the tank has a mass of 1.38×10^4 g. What is the density of olive oil in kilograms per liter?



92. Alkanes are a class of molecules that have the general formula C_nH_{2n+2}, where n is an integer (whole number). The table below gives the boiling points for the first five alkanes with an odd number of carbon atoms. Using the table, construct a graph with the number of carbon atoms on the x-axis.

Boiling point (°C)	Number of carbon atoms
−162.0	1
−42.0	3
36.0	5
98.0	7
151.0	9

a. What are the approximate boiling points for the C_2, C_4, C_6, and C_8 alkanes?
b. Which of these nine alkanes are gases at room temperature (20°C)?
c. How many of these nine alkanes are liquids at 350 K?
d. What is the approximate increase in boiling point per additional carbon atom in these alkanes?

***93.** Earth is approximately 1.5×10^8 km from the sun. How many minutes does it take light to travel from the sun to Earth? The speed of light is 3.0×10^8 m/s.

***94.**

The average density of Earth is 5.52 g/cm^3. Express this density in units of kg/dm^3.

95. How many kilograms of water (at 4°C) are needed to fill an aquarium that measures 40.0 cm by 20.0 cm by 30.0 cm?

Think Critically

96. Explain Is it possible for an object to lose weight but at the same time not lose mass? Explain your answer.

***97. Calculate** One of the first mixtures of metals, called amalgams, used by dentists for tooth fillings, consisted of 26.0 g of silver, 10.8 g of tin, 2.4 g of copper, and 0.8 g of zinc. How much silver is in a 25.0 g sample of this amalgam?

***98. Calculate** A cheetah can run 112 km/h over a 100-m distance. What is this speed in meters per second?

99. Evaluate You are hired to count the number of ducks on three northern lakes during the summer. In the first lake, you estimate 500,000 ducks, in the second 250,000 ducks, and in the third 100,000 ducks. You write down that you have counted 850,000 ducks. As you drive away, you see 15 ducks fly in from the south and land on the third lake. Do you change the number of ducks that you report? Justify your answer.

100. Describe What if ice were more dense than water? It would certainly be easier to pour water from a pitcher of ice cubes and water. Can you think of situations of more consequence?

101. Graph Plot these data that show how the mass of sulfur increases with an increase in volume. Determine the density of sulfur from the slope of the line.

Volume of sulfur (cm^3)	Mass of sulfur (g)
11.4	23.5
29.2	60.8
55.5	115
81.1	168

102. Analyze Data At 20°C, the density of air is 1.20 g/L. Nitrogen's density is 1.17 g/L. Oxygen's density is 1.33 g/L.
a. Will balloons filled with oxygen and balloons filled with nitrogen rise or sink in air?
b. Air is mainly a mixture of nitrogen and oxygen. Which gas is the main component? Explain.

ASSESSMENT

92. a. C_2 = −90°C, C_4 = 0°C, C_6 = 70°C, C_8 = 125°C
b. C_1 through C_4
c. three
d. From C_1 through C_9, the increase is approximately 39°C/additional carbon. Over the range C_3 through C_9, the increase is approximately 32°C/additional carbon.

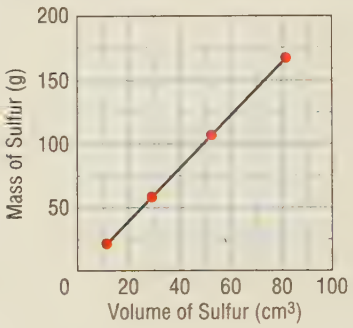
93. 8.3 min

94. 5.52 kg/dm^3

95. 24.0 kg of water

THINK CRITICALLY

96. Yes, the mass of an object is constant. The weight of an object varies with location.



97. 16.3 g

98. 31.1 m/s

99. You do not change your estimate. Counting the extra 15 ducks would suggest greater precision than was used in the estimate.

100. Answers will vary. Lakes would freeze solid from the bottom up; aquatic life would be destroyed; possible climate changes would occur.

101.

density of sulfur = 2.1 g/cm^3

102. a. The oxygen-filled balloon will sink; the nitrogen-filled balloon will rise.
b. Nitrogen; the "weighted" average density of air is closer to the density of nitrogen.

CHEMYSTERY

START A CONVERSATION After students have read through the CHEMystery, discuss the importance of quantifying a measure with units. **Ask** What problems can occur if people have to rely on the customs of the city they are in to interpret the measure of a value? *(Answers will vary.)* **Ask** What are some units used to measure distance? *(Sample answer: centimeter, mile, foot, kilometer)* **Ask** Do you think if you know a measurement is linear, such as distance, that then it is okay not to label the quantity with a unit? Explain. *(no, because the measurement could have been made in any one of several metric or nonmetric scales)* Explain to students that measured values should be of help to other people, not a hindrance. Point out that a value expressed without a unit can have a great effect on something else. Encourage students to make a concerted effort to write the units of a value throughout a calculation as well as when the final answer is computed.

CHEMYSTERY ANSWERS

111. 7.3 km

112. 43 minutes

113. **BIG**IDEA Answers will vary. Sample answers might discuss how the distances are rounded and expressed to one or two significant figures, or how the missing units result in an uncertainty in one's ability to gauge the magnitude of the measurements.

Concept Challenge

*103. **Calculate** The mass of a cube of iron is 355 g. Iron has a density of 7.87 g/cm^3. What is the mass of a cube of lead that has the same dimensions?

*104. **Calculate** Sea water contains 8.0×10^{-1} cg of the element strontium per kilogram of sea water. Assuming that all the strontium could be recovered, how many grams of strontium could be obtained from one cubic meter of sea water? Assume the density of sea water is 1.0 g/mL.

105. **Calculate** The density of dry air at 20°C is 1.20 g/L. What is the mass of air, in kilograms, of a room that measures 25.0 m by 15.0 m by 4.0 m?

106. **Graph** Different volumes of the same liquid were added to a flask on a balance. After each addition of liquid, the mass of the flask with the liquid was measured. Graph the data using mass as the dependent variable. Use the graph to answer these questions.

Volume (mL)	Mass (g)
14	103.0
27	120.4
41	139.1
55	157.9
82	194.1

a. What is the mass of the flask?
b. What is the density of the liquid?

*107. **Predict** A 34.5-g gold nugget is dropped into a graduated cylinder containing water. By how many milliliters does the measured volume increase if the nugget is completely covered by water? The density of water is 1.0 g/mL. The density of gold is 19.3 g/cm^3.

108. **Predict** Equal amounts of mercury, water, and corn oil are added to a beaker. Use Table 3.6 to help you anwer the following questions.
a. Describe the arrangement of the layers of liquids in the beaker.
b. A small sugar cube is added to the beaker. Describe its location.
c. What change will occur to the sugar cube over time?

Write About Science

109. **Describe** For one of the topics below, write a short paragraph that identifies both metric and nonmetric units that are commonly used to communicate information.
a. measurements used in cooking
b. measurements used in sports
c. measurements used in transportation

110. Connect to the **BIG**IDEA Explain how the three-step problem-solving approach defined in Chapter 1 (*Analyze, Calculate, Evaluate*) applies to problems that involve dimensional analysis.

CHEMYSTERY

Just Give Me a Sign

The road signs point to locations in England. Although England has adopted metric units for many everyday quantities, distances shown on road signs are not among them. The road signs above list distances in miles, a nonmetric unit. Speed-limit signs in England are typically expressed in miles per hour—also nonmetric. However, in the same country, gasoline is sold by metric units of volume (liters), fabric is measured in metric units of area (square meters), and the local weather report uses metric units of temperature (°C).

111. **Calculate** The relationship between kilometers and miles (mi) is 1 km = 0.621 mi. How far it is to Chipping in kilometers?

112. **Calculate** Suppose you encounter the road signs above while cycling. If your average speed is 18 km/h, how many minutes will it take you to reach Preston?

113. Connect to the **BIG**IDEA Describe two ways in which the road signs above might be considered examples of "uncertainty in measurement."

Answers

ENRICHMENT

103. Volume of iron = 45.1 cm^3
Mass of lead = 510 g Pb

104. 8.0 g Sr

105. 1.8×10^3 kg

106. **a.** 85 g **b.** 1.3 g/mL

107. 1.79 mL

108. **a.** corn oil on top of water on top of mercury
b. The density of sugar is greater than the density of water and less than the density of mercury; it floats between the layers of mercury and water.
c. The sugar cube will dissolve in the water over time.

WRITE ABOUT SCIENCE

109. Answers will vary. Students should be comfortable with recognizing metric and nonmetric units in any given measurement and have an intuitive idea of their magnitude.

110. Answers will vary. Students should understand that solving dimensional analysis problems uses the same general approach as any other chemistry problem, including setting up the problem, performing calculations, and checking the results for sense.

Standardized Test Prep for Indiana

Standard: C.1.7

Select the choice that best answers each question or completes each statement.

1. Which of these series of units is ordered from smallest to largest?
   (A) μg, cg, mg, kg
   (B) mm, dm, m, km
   (C) μs, ns, cs, s
   (D) nL, mL, dL, cL

2. Which answer represents the measurement 0.00428 g rounded to two significant figures?
   (A) 4.28×10^3 g
   (B) 4.3×10^3 g
   (C) 4.3×10^{-3} g
   (D) 4.0×10^{-3} g

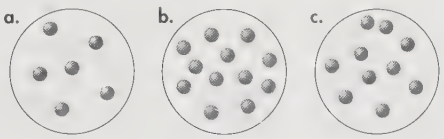
3. An over-the-counter medicine has 325 mg of its active ingredient per tablet. How many grams does this mass represent?
   (A) 325,000 g
   (B) 32.5 g
   (C) 3.25 g
   (D) 0.325 g

4. If 10^4 μm = 1 cm, how many $\mu m^3 = 1\ cm^3$?
   (A) 10^4
   (B) 10^6
   (C) 10^8
   (D) 10^{12}

5. If a substance contracts when it freezes, its
   (A) density will remain the same.
   (B) density will increase.
   (C) density will decrease.
   (D) change in density cannot be predicted.

For Questions 6–7, identify the known and the unknown. Include units in your answers.

6. The density of water is 1.0 g/mL. How many deciliters of water will fill a 0.5-L bottle?



7. A graduated cylinder contains 44.2 mL of water. A 48.3-g piece of metal is carefully dropped into the cylinder. When the metal is completely covered with water, the water rises to the 51.3-mL mark. What is the density of the metal?

Tips for Success

Interpret Diagrams Before you answer questions about a diagram, study the diagram carefully. Ask: What is the diagram showing? What does it tell me?

Use the diagrams below to answer Questions 8 and 9.

The atomic windows represent particles of the same gas occupying the same volume at the same temperature. The systems differ only in the number of gas particles per unit volume.

8. List the windows in order of decreasing density.

9. Compare the density of the gas in window (a) to the density of the gas in window (b).

For each question, there are two statements. Decide whether each statement is true or false. Then decide whether Statement II is a correct explanation for Statement I.

	Statement I		Statement II
10.	There are five significant figures in the measurement 0.00450 m.	BECAUSE	All zeros to the right of a decimal point in a measurement are significant.
11.	Precise measurements will always be accurate measurements.	BECAUSE	A value that is measured 10 times in a row must be accurate.
12.	A temperature in kelvins is always numerically larger than the same temperature in degrees Celsius.	BECAUSE	A temperature in kelvins equals a temperature in degrees Celsius plus 273.

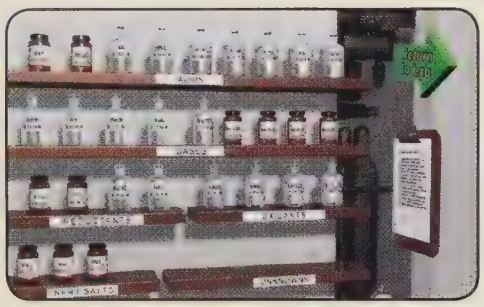
Virtual Chem Lab 5: Millikan Oil Drop Experiment
Virtual Chem Lab 6: Atomic Structure: Rutherford's Experiment

CHAPTER 4



What's Online

Students access guided step-by-step tutorials for solving various atomic structure problems.

Students can practice key problem-solving skills in an online problem set.

Identify the students who struggle with math by assigning an online math skills diagnostic test. These students can then improve and practice math skills using the MathXL tutorial system.

Students go into a virtual lab tour in which key experiments in the history of atomic theory are studied in a simulated laboratory environment.

Student watch animations of a selected figures from the chapter followed by questions to check for understanding.

Students watch an overview of a key chapter concept using real-world contexts and concrete examples and analogies. Each activity includes an interactive animation followed by analysis questions.

A scanning electron microscope was used to produce this color-enhanced image of nickel atoms.

100

IN ACADEMIC STANDARDS for SCIENCE

Nature of Science

- Regularly evaluate the work of their peers and in turn have their work evaluated by their peers.
- Explain that the body of scientific knowledge is organized into major theories, which are derived from and supported by the results of many experiments, and allow us to make testable predictions.
- Recognize that new scientific discoveries often lead to a re-evaluation of previously accepted scientific knowledge and of commonly held ideas.

Standard 2: Atomic Structure and the Periodic Table

C.2.1 Describe the historical development of the modern atomic theory.

Also covered C.2.2, C.2.3, C.2.4

Focus on ELL

1 CONTENT AND LANGUAGE Dissect the chapter title into two parts. Begin with the word *structure*. Give examples of real world objects or situations that have a structure. Explain that this chapter is about the structure of *atoms*. As a class brainstorm the meaning of an atom. Have students identify any other words in the lesson titles that they do not know. Add these words to the classroom word wall.

BEGINNING

LOW Write the unfamiliar words on the board and say them out loud.

HIGH Write the plural, noun, and adjective forms of the word *atom*.

INTERMEDIATE

LOW Have students use an English dictionary to find the meaning of the unfamiliar words and write the definitions in their notebooks.

HIGH Have students write an original sentence using each word.

ADVANCED: LOW/HIGH Have students discuss the meaning or synonyms of the unfamiliar words with an elbow partner.

BIGIDEA

ELECTRONS AND THE STRUCTURE OF ATOMS

Essential Questions:

1. *What components make up an atom?*
2. *How are atoms of one element different from atoms of another element?*

CHEMYSTERY

Artifact or Artifake?

Crystal skulls are shaped like a human skull and carved from quartz crystal. Crystal skulls are thought to have originated from pre-Columbian Central American cultures. If so, then crystal skulls would have been carved several hundred or even thousands of years ago. They would probably have been carved using primitive stone, wooden, and bone tools.

Although crystal skulls are displayed in museums throughout the world, none of them were found in an actual archaeological dig. This unusual circumstance has led to some debate about the history of the skulls. People have questioned whether crystal skulls were ever carved by people from ancient civilizations. Are these sculptures true artifacts that were carved in the pre-Columbian era, or are they just fakes?

▶ Connect to the BIGIDEA As you read about the structure of atoms, think about how scientists could identify whether a crystal skull is from an ancient civilization or is just a fake.

INDIANA'S ACADEMIC STANDARDS FOR SCIENCE

Atomic Structure and the Periodic Table C.2.1, C.2.2, C.2.3, C.2.4

Introduce the Chapter

IDENTIFY MISCONCEPTIONS Students may think of atoms as either solid spheres or composed of smaller particles that are close together. Use the activity to help students develop a clearer understanding of atomic structure.

Activity *You will need several small balls of modeling clay, a piece of foam board, and about fifteen straight pins with ball heads.* Place one clay ball and the foam board on a table. Cluster about 10 of the pins in the center of the foam board to model an atomic nucleus. Insert the other pins around the rest of the foam board to model electrons. **Ask** Which of these is the best model for an atom? *(the pins)* **Ask** What makes the ball of clay a poor model? *(It is solid.)*

Gently push the balls of clay close together into a sphere. Explain that each ball of clay represents a particle in the atom. Have students compare this clay sphere to the pin model. **Ask** Which model is a better representation of an atom? *(pin model)* Why? *(The pin model represents tiny particles with a large amount of space between them. The clay model has no space between the particles.)* Explain that in this chapter, students will begin their study of atomic structure.

UbD

Understanding by Design

Students are building toward an understanding of the characteristics of individual atoms and the structural differences between different types of atoms.

PERFORMANCE GOALS At the end of Chapter 4, students will be able to answer the essential questions by applying their knowledge of the structure of the nuclear atom. Students will also be able to distinguish different types of atoms.

ESSENTIAL QUESTIONS Read the essential questions aloud. **Ask** Why do you think it important to understand the structure of the atom? *(The structure of the atom determines the properties of matter.)* **Ask** Can you predict ways that one atom might be different from another atom? Do you think all atoms of gold, for example, are identical to one another? *(Engage students in a discussion of reasonable predictions.)*

BIGIDEA Activate prior knowledge by having students describe what they know about elements. Use the photo of the atoms to help students connect to the concepts they will learn in this chapter. Explain that a scanning-electron microscope (SEM) produced the image by moving a beam of electrons across the surface of a sample of matter. **Ask** What information does this picture tell you about the sample being scanned? *(All of the atoms have a similar appearance.)* **Ask** What can you infer about the sample from this image? *(All of the nickel atoms look alike.)* Engage students in a discussion of what other details of the photo might tell them about atoms.

CHEMYSTERY Have students read over the CHEMystery. Connect the CHEMystery to the Big Idea by having students consider differences in markings caused by carving the crystals. Carving the crystals with primitive tools would leave markings that are rough and uneven. Ask students to predict what a microscopic inspection of the crystals would show if more advanced carving methods had been used. Then have students consider how this microscopic inspection could be made. As a hint, have students look at the photo of atoms on this page. **Ask** How do you think this technology is used to investigate the crystal skull mystery? *(Discuss all plausible ideas.)*

LESSON 4.1

Key Objectives

4.1.1 EXPLAIN how Democritus and John Dalton described atoms.

4.1.2 IDENTIFY instruments used to observe individual atoms.

CHEMISTRY & YOU

Q: *How do you study something that you cannot see?* It is sometimes fun to try to figure out what is inside a present before opening it. You could look at the shape or weight of the box. Or maybe you would shake the box a little to find out if anything moved around or made noise inside the box. Similar to how you might study a giftwrapped present, scientists often study things that cannot be seen with the naked eye. In this lesson, you will learn how scientists obtained information about the atoms that they couldn't see.

Key Questions

How did the concept of the atom change from the time of Democritus to the time of John Dalton?

What instruments are used to observe individual atoms?

Vocabulary

- atom
- Dalton's atomic theory

READING SUPPORT

Build Vocabulary: *Word Origins* *Atom* comes from the Greek word *atomos*, meaning "indivisible." ***How does the word origin of atom relate to Dalton's atomic theory?***

Early Models of the Atom

How did the concept of the atom change from the time of Democritus to the time of John Dalton?

Using your unaided eyes, you cannot see the tiny fundamental particles that make up matter. Yet, all matter is composed of such particles, which are called atoms. An **atom** is the smallest particle of an element that retains its identity in a chemical reaction.

The concept of the atom intrigued a number of early scholars. Although these philosophers and scientists could not observe individual atoms, they still were able to propose ideas about the structure of atoms.

Democritus's Atomic Philosophy The Greek philosopher Democritus (460 B.C.–370 B.C.) was among the first to suggest the existence of atoms. **Democritus reasoned that atoms were indivisible and indestructible.** Although Democritus's ideas agreed with later scientific theory, they did not explain chemical behavior. They also lacked experimental support because Democritus's approach was not based on the scientific method.

Dalton's Atomic Theory The real nature of atoms and the connection between observable changes and events at the atomic level were not established for more than 2000 years after Democritus's death. The modern process of discovery regarding atoms began with John Dalton (1766–1844), an English chemist and schoolteacher. **By using experimental methods, Dalton transformed Democritus's ideas on atoms into a scientific theory.** Dalton studied the ratios in which elements combine in chemical reactions.

Focus on ELL

1 CONTENT AND LANGUAGE Direct students' attention to the words *indivisible* and *indestructible* on this page. Have students identify the roots of these words. (divisible *and* destructible) Have students look up the definitions of all four words in the dictionary. Then, have students use the differences between the definitions of *indivisible* and *indestructible* and their root words to identify the meaning of the prefix *in-*. (*in-* means "not") Have students brainstorm other words with this prefix that also have meanings opposite those of their roots.

2 FRONTLOAD THE LESSON Have students draw a compare/contrast table with one column labeled *Democritus* and another labeled *Dalton*. Tell students they will use their tables to track the similarities and differences between the two men's beliefs about the atom as they work through the lesson.

3 COMPREHENSIBLE INPUT Read aloud the four parts of Dalton's theory, demonstrating each point with molecular models. Use an iron bar, iron filings, and a magnet to reinforce the concept that different forms of an element all have the same properties because they are made of the same atoms.

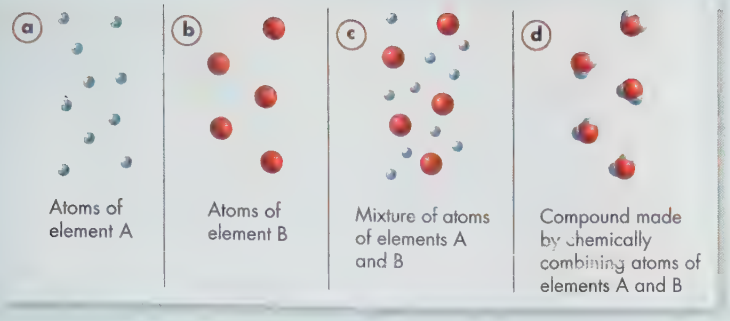

Figure 4.1
Dalton's Atomic Theory
According to Dalton's atomic theory, an element is composed of only one kind of atom, and a compound is composed of particles that are chemical combinations of different kinds of atoms.
Interpret Diagrams ***How does a mixture of atoms of different elements differ from a compound?***

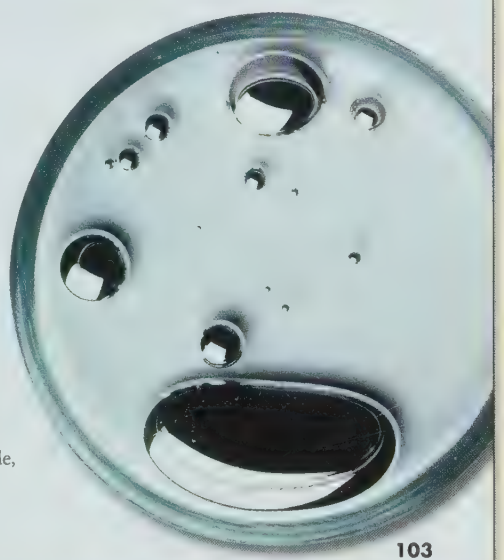
Based on the results of his experiments, Dalton formulated hypotheses and theories to explain his observations. The result of his work is known as **Dalton's atomic theory,** which includes the ideas illustrated in Figure 4.1 and listed below.

1. All elements are composed of tiny indivisible particles called atoms.
2. Atoms of the same element are identical. The atoms of any one element are different from those of any other element.
3. Atoms of different elements can physically mix together or can chemically combine in simple whole-number ratios to form compounds.
4. Chemical reactions occur when atoms are separated from each other, joined, or rearranged in a different combination. Atoms of one element, however, are never changed into atoms of another element as a result of a chemical reaction.

CHEMISTRY & YOU

Q: *How was John Dalton able to study atoms even though he couldn't observe them directly? What evidence did he use to formulate his atomic theory?*

Sizing up the Atom



What instruments are used to observe individual atoms?

The liquid mercury in Figure 4.2 illustrates Dalton's concept of the atom. Whether the size of the drop of mercury is large or small, all drops have the same properties because they are all made of the same kind of atoms.

A coin the size of a penny and composed of pure copper (Cu) is another example. If you were to grind the copper coin into a fine dust, each speck in the small pile of shiny red dust would still have the properties of copper. If by some means you could continue to make the copper dust particles smaller, you would eventually come upon a particle of copper that could no longer be divided and still have the chemical properties of copper. This final particle is an atom.

Atoms are very small. A pure copper coin the size of a penny contains about 2×10^{22} atoms. By comparison, Earth's population is only about 7×10^{9} people. There are about 3×10^{12} times as many atoms in the coin as there are people on Earth. If you could line up 100,000,000 copper atoms side by side, they would produce a line only 1 cm long!

Figure 4.2 Drops of Mercury
This petri dish contains drops of liquid mercury. Every drop, no matter its size, has the same properties. Even if you could make a drop the size of one atom, it would still have the chemical properties of mercury.

Foundations for Reading

BUILD VOCABULARY Discuss the meaning of the term *scientific theory. (an explanation of the way the world works, based on observation)*

READING STRATEGY Ask students to think about these questions as they read this chapter.

- What could you do if someone asked you to describe something that is too small to see?
- How would you find out what it looked like?

Explain

Early Models of the Atoms

START A CONVERSATION Explain that John Dalton's work, published in 1808, became the basis for the modern atomic theory. This model represented the atom as a simple sphere with no internal structure. Point out how experimental data have been used to test and refine atomic theory over time.

USE VISUALS Direct students' attention to Figure 4.1. **Ask** How many atoms of A and of B form one particle in Figure 4.1d? *(2 A and 1 B)* Do you think that a mixture, shown in Figure 4.1c, always leads to compounds, shown in Figure 4.1d? Why? *(No; some atoms may not readily combine.)*

CHEMISTRY & YOU Dalton used experimental methods to mix elements and observe how they combined with each other. He studied the ratios by which elements combine with each other to propose what is now known as Dalton's atomic theory.

Check for Understanding

BIG IDEA ELECTRONS AND THE STRUCTURE OF ATOMS Assess students' understanding of Dalton's atomic theory. **Ask** How might Dalton have used his observations of chemical reactions to develop his atomic theory? *(Based on his understanding of chemical reactions, he would most likely know that elements are present in compounds in fixed proportions, and so might hypothesize that the atoms of these elements were also present in fixed proportions. He also might have hypothesized that because the same elements are present in reactants and products and no new elements appeared as a result of the reaction that atoms can be rearranged, separated, or joined but that no atoms are changed into atoms of a new element.)*

ADJUST INSTRUCTION If students are having difficulty understanding Dalton's atomic theory, review the four parts of the theory and Figure 4.1.

Answers

READING SUPPORT Dalton's atomic theory states that atoms are indivisible particles. "Indivisible" is the meaning of *atomos*.

FIGURE 4.1 In a mixture of atoms of different elements, each element in the mixture retains its chemical properties. In a compound, different elements have been combined to form a new substance with chemical properties different from its component elements. Atoms are separated, joined, or rearranged.

Explain

Sizing up the Atom

USE VISUALS Point out that the image in Figure 4.3 is greatly magnified. Explain that a nanometer is 1×10^{-9} meters. **Ask** If the nanocars are about 2 nm across, about how many atoms wide are the nanocars if the average width of the atoms is 1.0×10^{-10} m? *(about 20 atoms wide)*

Evaluate

Informal Assessment

Have students evaluate and criticize the following statements according to Dalton's theory.

- "All atoms are identical." *(False. Dalton said: "All atoms of a given element are identical.")*
- "Chemical reactions occur when atoms of one element change into atoms of another element." *(False. Chemical reactions occur when atoms are separated, joined, or rearranged. The elemental identity of atoms does not change during chemical reactions.)*

Then have students complete the 4.1 Lesson Check.

Reteach

Review Dalton's model of the atom. Discuss how a scanning electron microscope might be used to support or contest Dalton's theory, referring students back to the opening photo as needed. *(No matter how small the sample, you can see that that there are many similar atoms in each sample. You could also see where atoms are and whether they change after a chemical reaction.)*

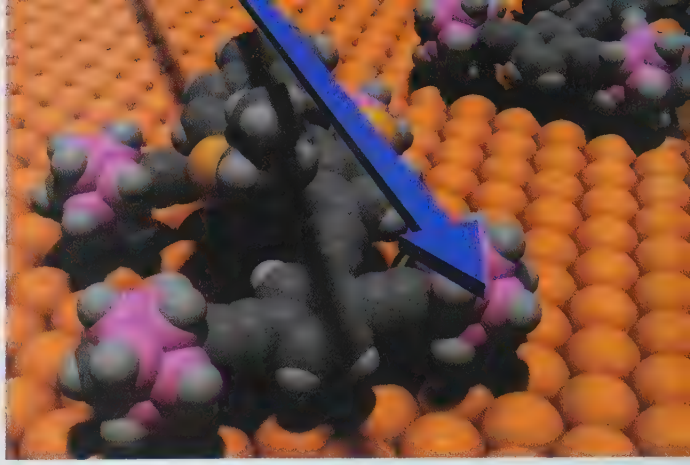


Figure 4.3 Model of a Nanocar
These nanocars are each made of a single molecule. Each nanocar is only about 2 nanometers across. A light-activated paddle wheel on the car propels the car so it can move. The arrow represesents the direction the nanocar moves.

The radii of most atoms fall within the range of 5×10^{-11} m to 2×10^{-10} m. Does seeing individual atoms seem impossible? **Despite their small size, individual atoms are observable with instruments such as scanning electron microscopes.** In scanning electron microscopes, a beam of electrons is focused on the sample. Electron microscopes are capable of much higher magnifications than light microscopes.

With the help of electron microscopes, individual atoms can even be moved around and arranged in patterns. The ability to move individual atoms holds future promise for the creation of atomic-sized electronic devices, such as circuits and computer chips. An example of a device made from individual atoms is the nanocar shown in Figure 4.3. This atomic-scale, or "nanoscale," technology could become essential to future applications in medicine, communications, solar energy, and space exploration.

4.1 LessonCheck

1. **Review** How did Democritus characterize atoms?
2. **Explain** How did Dalton advance the atomic philosophy proposed by Democritus?
3. **Identify** What instrument can be used to observe individual atoms?
4. **Explain** In your own words, explain the main ideas of Dalton's atomic theory.
5. **Evaluate** Explain why the ideas on atoms proposed by Dalton constitute a theory, while the ideas proposed by Democritus do not.
6. **Identify** What is the range of the radii of most atoms in nanometers (nm)?
7. **Calculate** A sample of copper with a mass of 63.5 g contains 6.02×10^{23} atoms. Calculate the mass of a single copper atom.

BIGIDEA
ELECTRONS AND THE STRUCTURE OF ATOMS

8. According to Dalton's theory, is it possible to convert atoms of one element into atoms of another? Explain.

Lesson Check Answers

1. as indivisible and indestructible
2. by using experimental methods
3. a scanning electron microscope
4. Answers should include the ideas that all matter is composed of atoms; atoms of different elements differ; and chemical change involves a rearrangement of atoms.
5. Democritus's ideas were not based on experimental results and did not explain chemical behavior. Dalton's ideas were empirically based and did explain chemical behavior; his experiments showed that the ratios in which elements combined were whole numbers.
6. 5×10^{-2} nm to 2×10^{-1} nm
7. 1.05×10^{-22} g
8. **BIG**IDEA Atoms of one element are never changed into atoms of another element as a result of a chemical reaction.

4.2 Structure of the Nuclear Atom

C.2.1 Modern atomic theory: historic development; C.2.2 Subatomic particles and atomic structure; C.2.3 Isotopes, atomic number, and atomic mass

CHEMISTRY & YOU

Q: *You can X-ray a person's hand to see inside it—but how can you see inside an atom?* You may have seen X-rays like the one of the hand shown here. Doctors often use X-rays to see bones and other structures that cannot be seen through the skin. Scientists tried to figure out what was inside an atom without being able to see inside the atom. In this lesson, you will learn the methods scientists used to "see" inside an atom.

Key Questions

- ***What are three kinds of subatomic particles?***
- ***How can you describe the structure of the nuclear atom?***

Vocabulary

- electron
- cathode ray
- proton
- neutron
- nucleus

Subatomic Particles

What are three kinds of subatomic particles?

Much of Dalton's atomic theory is accepted today. One important change, however, is that atoms are now known to be divisible. They can be broken down into even smaller, more fundamental particles, called subatomic particles. **Three kinds of subatomic particles are electrons, protons, and neutrons.**

Electrons In 1897, the English physicist J. J. Thomson (1856–1940) discovered the electron. **Electrons** are negatively charged subatomic particles. Thomson performed experiments that involved passing electric current through gases at low pressure. He sealed the gases in glass tubes fitted at both ends with metal disks called electrodes. The electrodes were connected to a source of electricity, as shown in Figure 4.4. One electrode, the anode, became positively charged. The other electrode, the cathode, became negatively charged. The result was a glowing beam, or **cathode ray,** that traveled from the cathode to the anode.

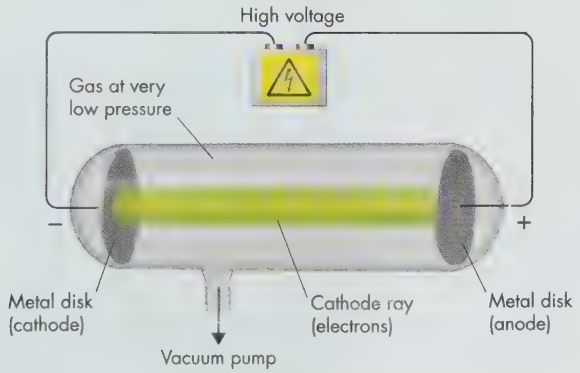

Figure 4.4
Cathode-Ray Tube
In a cathode-ray tube, electrons travel as a ray from the cathode (–) to the anode (+). Televisions used to be made with a specialized type of cathode-ray tube.

Focus on ELL

1 CONTENT AND LANGUAGE Write the term *subatomic* on the board. Explain that the prefix *sub-* means "below" or "a part of". Have students brainstorm the literal meaning of *subatomic. (below atomic)* Now write the words *electron*, *proton*, and *neutron* on the board. Explain that in these three words, the suffix *–on* means "subatomic particle".

2 FRONTLOAD THE LESSON Have students preview Figure 4.4 and identify any similarities and differences between the parts of a cathode ray tube and parts of a battery. Explain that, just as a battery generates a stream of electrons that flow through an electrical circuit, a cathode ray generates a stream of electrons that travel as a beam.

3 COMPREHENSIBLE INPUT Draw Table 4.1 on the board, using a contrasting color to write the mathematical signs in the *Symbols* column. Use the same color to write the values of the relative charges. Point out the relative mass of an electron, and ask students to locate the text where this figure is referenced.

LESSON 4.2

Key Objectives

4.2.1 IDENTIFY three types of subatomic particles.

4.2.2 DESCRIBE the structure of atoms according to the Rutherford atomic model.

Engage

CHEMISTRY & YOU Have students study the opening photo and read the accompanying text.
Ask How could you determine what your hand looks like under the skin without dissecting it? *(X-rays, CT scans, or MRI scans)* Explain that scientists use technology to "see" inside atoms, just as doctors use it to "see" inside the body.

Build Background

Ask Do you have an electronic item in your home that uses a CRT? *(Sample answers: a television or a computer monitor)* Explain that television and computer CRTs have a source of rays at the small end. The rays are projected on the large receiving end to create the display.

IN ACADEMIC STANDARDS for SCIENCE

- Focus on the development of explanatory models based on their observations during laboratory investigations.
- Explain that the body of scientific knowledge is organized into major theories, which are derived from and supported by the results of many experiments, and allow us to make testable predictions.

C.2.3 Determine the number of protons, neutrons, and electrons in isotopes and in those isotopes that comprise a specific element. Relate these numbers to atomic number and mass number.

Also covered C.2.1, C.2.2

Foundations for Reading

BUILD VOCABULARY Have students think of words that start with the same word parts as the three subatomic particles described in this section: neutron, electron, and proton. *(Sample answer: neutral, electric, protein)* Words that students already know may help them remember the meaning of new terms.

Explore

Teacher Demo

PURPOSE To demonstrate a cathode-ray tube and observe properties of cathode rays

MATERIALS cathode-ray tube, magnet

PROCEDURE Demonstrate a cathode-ray tube in class. Use a magnet to deflect the beam of particles. Review the components of a cathode-ray tube, and discuss the connection to television picture tubes and computer monitors.

EXPECTED OUTCOME Students should be able to explain how the CRT works and see how the cathode ray is deflected by a magnetic field.

Explain

Subatomic Particles

USE VISUALS Have students study Table 4.1, and compare the masses and charges of the three elementary particles. Students should recognize from this comparison that the mass of an atom is due mainly to the number of protons and neutrons that it has. Point out that the assigned charges for protons and electrons are relative charges. **Ask** What particles make up most of the mass of an atom? *(protons and neutrons)* **Ask** Why are relative charges and mass useful in talking about subatomic particles? *(The actual values are unwieldy numbers.)* The absolute charge on an electron is 1.602177×10^{-19} coulombs.

Thomson found that a cathode ray is deflected by electrically charged metal plates, as in Figure 4.5a. A positively charged plate attracts the cathode ray, while a negatively charged plate repels it. Thomson knew that opposite charges attract and like charges repel, so he hypothesized that a cathode ray is a stream of tiny negatively charged particles moving at high speed. Thomson called these particles corpuscles; later they were named electrons.

To test his hypothesis, Thomson set up an experiment to measure the ratio of an electron's charge to its mass. He found this ratio to be constant. Also, the charge-to-mass ratio of electrons did not depend on the kind of gas in the cathode-ray tube or the type of metal used for the electrodes. Thomson concluded that electrons are a component of the atoms of all elements.

The U.S. physicist Robert A. Millikan (1868–1953) carried out experiments to find the quantity of an electron's charge. In his oil-drop experiment, Millikan suspended negatively charged oil droplets between two charged plates. He then changed the voltage on the plates to see how this affected the droplets' rate of fall. From his data, he found that the charge on each oil droplet was a multiple of 1.60×10^{-19} coulomb, meaning this must be the charge of an electron. Using this charge value and Thomson's charge-to-mass ratio of an electron, Millikan calculated an electron's mass. Millikan's values for electron charge and mass are similar to those accepted today. An electron has one unit of negative charge, and its mass is 1/1840 the mass of a hydrogen atom.

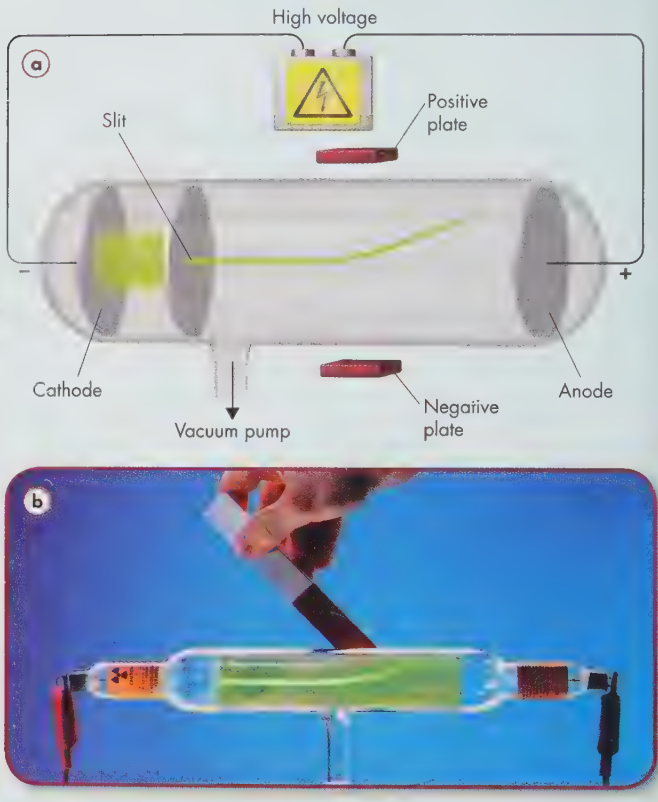

Figure 4.5
Thomson's Experiment
a. Thomson found that cathode rays are attracted to metal plates that have a positive electrical charge. **b.** A cathode ray can also be deflected by a magnet.
Infer ***If a cathode ray is attracted to a positively charged plate, what can you infer about the charge of the particles that make up the cathode ray?***

Differentiated Instruction

LPR LESS PROFICIENT READERS Direct students to use Figures 4.4 and 4.5 to describe J.J. Thomson's experiment with cathode-ray tubes in their own words.

L1 SPECIAL STUDENTS Prior to explaining subatomic particles, divide students into small groups. Give each group pair of inflated rubber balloons (be aware of any latex allergies in the class) and a swatch of wool cloth. Have students rub the balloons vigorously with the wool. Have students test the balloons against different objects and against each other to discover how opposite charges attract and like charges repel. Use this activity as a lead in to Thompson's cathode ray experiment.

L3 ADVANCED STUDENTS Have students use the Internet or library to find the original papers for the discoveries described in this chapter and write a report on what they have learned.

Table 4.1

Properties of Subatomic Particles

Particle	Symbol	Relative charge	Relative mass (mass of proton = 1)	Actual mass (g)
Electron	e^-	1−	1/1840	9.11×10^{-28}
Proton	p^+	1+	1	1.67×10^{-24}
Neutron	n^0	0	1	1.67×10^{-24}

Protons and Neutrons If cathode rays are electrons given off by atoms, what remains of the atoms that have lost the electrons? For example, after a hydrogen atom (the lightest kind of atom) loses an electron, what is left? You can think through this problem using four simple ideas about matter and electric charges. First, atoms have no net electric charge; they are electrically neutral. (One important piece of evidence for electrical neutrality is that you do not receive an electric shock every time you touch something!) Second, electric charges are carried by particles of matter. Third, electric charges always exist in whole-number multiples of a single basic unit; that is, there are no fractions of charges. Fourth, when a given number of negatively charged particles combines with an equal number of positively charged particles, an electrically neutral particle is formed.

Considering all of this information, it follows that a particle with one unit of positive charge should remain when a typical hydrogen atom loses an electron. Evidence for such a positively charged particle was found in 1886, when Eugen Goldstein (1850–1930) observed a cathode-ray tube and found rays traveling in the direction opposite to that of the cathode rays. He called these rays canal rays and concluded that they were composed of positive particles. Such positively charged subatomic particles are called **protons.** Each proton has a mass about 1840 times that of an electron.

In 1932, the English physicist James Chadwick (1891–1974) confirmed the existence of yet another subatomic particle: the neutron. **Neutrons** are subatomic particles with no charge but with a mass nearly equal to that of a proton. Table 4.1 summarizes the properties of these subatomic particles. Although protons and neutrons are exceedingly small, theoretical physicists believe that they are composed of yet smaller subnuclear particles called *quarks.*

The Atomic Nucleus

How can you describe the structure of the nuclear atom?

When subatomic particles were discovered, scientists wondered how the particles were put together in an atom. This question was difficult to answer, given how tiny atoms are. Most scientists—including J. J. Thomson, discoverer of the electron—thought it likely that electrons were evenly distributed throughout an atom filled uniformly with positively charged material. In Thomson's atomic model, known as the "plum-pudding model," electrons were stuck into a lump of positive charge, similar to raisins stuck in dough. This model of the atom turned out to be short-lived, however, due to the work of a former student of Thomson, Ernest Rutherford (1871–1937), shown in Figure 4.6.

Figure 4.6 Ernest Rutherford Born in New Zealand, Rutherford was awarded the Nobel Prize in Chemistry in 1908. His portrait appears on the New Zealand $100 bill.

UbD Check for Understanding

The Essential Question **What structures make up an atom?**

Give each student an index card. Assess students' knowledge of subatomic particles by reading out loud the description of each of the three kinds of particles. Students should write the name of the particle on the card in the order in which they were stated. Then ask students to indicate where each particle is located within the atom. *(electron, proton, and neutron; protons and neutrons are located inside the nucleus, electrons are located outside)*

ADJUST INSTRUCTION If students are having difficulty remembering which particles are located inside the nucleus, have them review Rutherford's atomic model by drawing and labeling an atom.

Explore

Teacher Demo

PURPOSE To trace the history of atomic models, and examine the role of the scientific method in the development of such models

MATERIALS Library or Internet access

PROCEDURE Have students create a timeline that traces the development of the atomic model. Have them note the data that led to an existing model being changed.

EXPECTED OUTCOME Students' timelines should list at least some of the atomic models shown on page 133. Students should be able to explain how certain scientific discoveries (e.g., Rutherford's gold foil experiment) resulted in the revision of the prevailing atomic model at the time.

Extend

Explain to students that by 1887, the British scientist William Crookes knew that metal atoms contained negatively charged particles. He used a cathode ray tube containing hydrogen gas at low pressure, and discovered that hydrogen contains positive charges. Ask students to research the following: What conclusion about the mass of the atom and the mass of its protons was derived from Crookes's findings? *(The mass of an atom is greater than its proton content.)* Which subatomic particle accounted for this additional mass? *(the neutron)*

Answers

FIGURE 4.5 The particles are negative. A negatively charged plate repels a cathode ray.

Explain

USE AN ANALOGY Explain to students that the ratio of the size of the nucleus to the size of an atom is about 10^{-5}. Discuss how small the nucleus is compared to the entire atom. Explain that if a housefly sitting on second base in a baseball stadium represented the nucleus of an atom, the rest of the atom would be the size of the stadium.

Evaluate

Informal Assessment

Have each student come to your desk and orally state in one minute or less one of the discoveries by Thomson, Millikan, or Rutherford. Then ask them to describe how the discovery led to the current understanding of atomic structure. Then have students complete the 4.2 Lesson Check.

Reteach

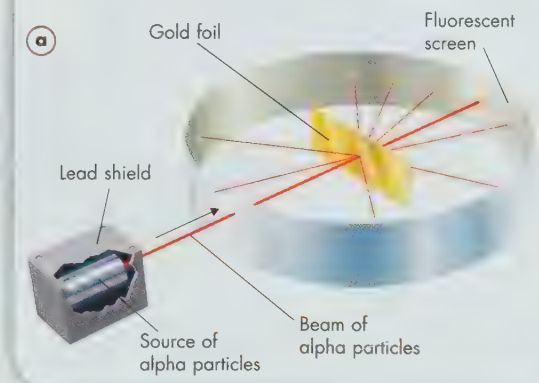
Have students review Table 4.1. Ask them to create a table or diagram to compare the characteristics of electrons, protons, and neutrons.

CHEMISTRY & YOU Scientists observed the behavior of atoms in different experimental conditions. This gave them clues as to what is inside an atom without actual "seeing" inside an atom.

CHEMISTRY & YOU

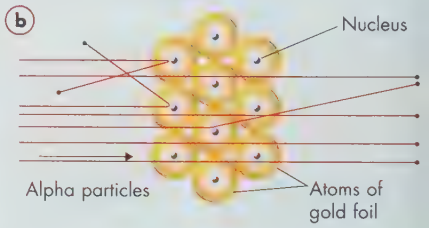
Q: *How did scientists "see" inside an atom to determine the structures that are inside an atom?*

Rutherford's Gold-Foil Experiment In 1911, Rutherford and his co-workers at the University of Manchester, England, wanted to test the existing plum-pudding model of atomic structure. So, they devised the gold-foil experiment. Their test used alpha particles, which are helium atoms that have lost their two electrons and have a double positive charge because of the two remaining protons. In the experiment, illustrated in Figure 4.7, a narrow beam of alpha particles was directed at a very thin sheet of gold foil. According to the prevailing theory, the alpha particles should have passed easily through the gold, with only a slight deflection due to the positive charge thought to be spread out in the gold atoms.



Rutherford's results were that most alpha particles went straight through the gold foil, or were slightly deflected. However, what was surprising is that a small fraction of the alpha particles bounced off the gold foil at very large angles. Some even bounced straight back toward the source. Rutherford later recollected, "This is almost as incredible as if you fired a 15-inch shell at a piece of tissue paper and it came back and hit you."

The Rutherford Atomic Model Based on his experimental results, Rutherford suggested a new theory of the atom. He proposed that the atom is mostly empty space, thus explaining the lack of deflection of most of the alpha particles. He concluded that all the positive charge and almost all the mass are concentrated in a small region that has enough positive charge to account for the great deflection of some of the alpha particles. He called this region the nucleus. The **nucleus** is the tiny central core of an atom and is composed of protons and neutrons.



VIRTUAL LAB

Figure 4.7 Rutherford's Experiment
Rutherford's gold-foil experiment yielded evidence of the atomic nucleus.

a. Rutherford and his co-workers aimed a beam of alpha particles at a sheet of gold foil surrounded by a fluorescent screen. Most of the particles passed through the foil with no deflection at all. A few particles were greatly deflected.

b. Rutherford concluded that most of the alpha particles pass through the gold foil because the atom is mostly empty space. The mass and positive charge are concentrated in a small region of the atom. Rutherford called this region the nucleus. Particles that approach the nucleus closely are greatly deflected.

See Rutherford's gold-foil experiment ***animated online.***

Focus on ELL

4 LANGUAGE PRODUCTION Have students work in partners to complete the Quick Lab. Make sure each pairing has ELLs of varied language proficiencies, so that a more proficient student can help a less proficient one. Have students work according to their proficiency level.

BEGINNING: LOW/HIGH Model this lab for these students. Show them your data, sketch, and measurements. Explain your method for guessing what is in the box.

INTERMEDIATE: LOW/HIGH Ask students to brainstorm what they think they may observe, prior to performing each step. Allow students to orally present their results.

ADVANCED: LOW/HIGH Ask students to present to the class their sketch, data, and interpretation of the object in one of the boxes.

The Rutherford atomic model is known as the nuclear atom. **In the nuclear atom, the protons and neutrons are located in the positively charged nucleus. The electrons are distributed around the nucleus and occupy almost all the volume of the atom.** According to this model, the nucleus is tiny and densely packed compared with the atom as a whole. If an atom were the size of a football stadium, the nucleus would be about the size of a marble.

Although it was an improvement over Thomson's model of the atom, Rutherford's model turned out to be incomplete. In Chapter 5, you will learn how the Rutherford atomic model had to be revised in order to explain the chemical properties of elements.

Quick Lab

Using Inference: The Black Box

Purpose To determine the shape of a fixed object inside a sealed box without opening the box

Materials

- **box containing a regularly shaped object fixed in place and a loose marble**

Procedure

1. Do not open the box.
2. Manipulate the box so that the marble moves around the fixed object.
3. Gather data (clues) that describe the movement of the marble.
4. Sketch a picture of the object in the box, showing its shape, size, and location within the box.
5. Repeat this activity with a different box containing a different object.

Analyze and Conclude

1. **Compare** Find a classmate who had a box with the same letter as yours, and compare your findings.
2. **Apply Concepts** Think about the experiments that have contributed to a better understanding of the atom. Which experiment does this activity remind you of?

4.2 LessonCheck

9. **Review** What are three types of subatomic particles?
10. **Explain** How does the Rutherford model describe the structure of atoms?
11. **Review** What are the charges and relative masses of the three main subatomic particles?
12. **Explain** Describe Thomson's and Millikan's contributions to atomic theory.
13. **Compare and Contrast** Compare Rutherford's expected outcome of the gold-foil experiment with the actual outcome.
14. **Analyze Data** What experimental evidence led Rutherford to conclude that an atom is mostly empty space?
15. **Compare and Contrast** How did Rutherford's model of the atom differ from Thomson's?

Explore

QuickLab

PURPOSE The students will determine the shape of the hidden object by analyzing the rebound paths of a marble rolled at the object.

SKILLS FOCUS Observing, inferring

PREP TIME 5 minutes

CLASS TIME 10 minutes

MATERIALS box containing a regularly shaped object fixed in place and a loose marble

ADVANCE PREP Cut geometric shapes—such as a triangle, circle, or L, from a sheet of 1-inch plastic foam.

EXPECTED OUTCOME Students' inferences may or may not be different for the same object.

ANALYZE AND CONCLUDE

1. See Expected Outcome.
2. The activity simulates the strategy that Rutherford used to probe the structure of metal atoms. Like the students, Rutherford and his coworkers were also faced with the problem of identifying properties of an object not visible to the eye.

FOR ENRICHMENT Make a more challenging black box for students who have an easy time with the simple boxes. Put two single objects in one box, or a single object with a complex shape.

Lesson Check Answers

9. protons, neutrons, and electrons
10. A positively charged nucleus surrounded by electrons, which occupy most of the volume.
11. proton, positive charge, relative mass = 1; electron, negative charge, relative mass = 1/1840; neutron, no charge, relative mass = 1
12. Thomson passed an electric current through sealed glass tubes filled with gases. The resulting glowing beam consisted of tiny negatively charged particles moving at high speed. Thomson concluded that electrons must be parts of the atoms of all elements. Millikan determined the charge and mass of the electron.
13. Rutherford expected all the alpha particles to pass straight through with little deflection. He found that most alpha particles passed straight through, but some particles were deflected at very large angles—and some even bounced straight back.
14. The great majority of the alpha particles passed straight through the gold foil.
15. Rutherford's atomic model described the atom as having a positively charged, dense nucleus that is tiny compared to the atom as a whole. In Thomson's plum-pudding model, electrons were stuck in a chunk of positive charge.

Electron Microscopy

CHEMISTRY & YOU Electron microscopes are capable of much greater levels of magnification than light microscopes, but their real power lies in their resolution. Resolution refers to the degree of detail that is revealed by a microscope. The greater a microscope's resolution, the more detail that can be seen in the images it transmits. Light microscopes rely on the natural reflective, refractive, and absorbent behaviors of light to make objects visible under magnification. However, these same behaviors can inhibit the degree of resolution, regardless of the magnitude of magnification. Thus, the resolution of a typical compound light microscope is about 200 nm. In contrast, some SEMs can achieve a resolution of 5 nm at high magnification.

Pose the following question to students: *How does the behavior of light inhibit the ability of a light microscope to deliver images with high resolution?* You may need to assist students in the following ways:

- Waves of visible light occur in wavelengths from 400 nm to 700 nm.
- The light provided to a light microscope by its mirror or electric light source are unfocused and spread out from the light source, while that electron beam in an SEM is highly focused and narrow.
- Light waves reflected by and transmitted through the object are subject to interference from each other and from incident light from both the source and from the microscope's surroundings.
- Some light waves transmitted through the sample may be directed away from the lens of the microscope.

CHEMISTRY & YOU: TECHNOLOGY

Electron Microscopy

Within 30 years of J. J. Thomson's discovery of the electron, scientists were studying how to produce images of objects by using an electron beam. In 1931, German scientists Ernst Ruska and Max Knoll built the first electron microscope. There are two types of electron microscopes, scanning electron microscopes (SEM) and transmission electron microscopes (TEM). The images shown here are from SEMs. In an SEM, a beam of electrons is focused down to a very small diameter and scanned across the sample. Most materials eject electrons when the electron beam hits them. The location of the ejected electrons is detected and used to produce an image.

A typical light microscope is capable of magnifying an object 1000 times. An electron microscope can magnify an object over 100,000 times. Another advantage of electron microscopes is their higher resolution. Resolution is the ability to differentiate two objects that are very close to each other. So, an electron microscope has the ability to produce a clearer image than a light microscope at the same magnification. Electron microscopes do not produce color images. The color images shown here have false color that has been added to the images. Electron microscopes are useful in chemistry, but also in other fields, such as archeolology, pharmacology and quality assurance testing.

SEM This microscope is a scanning electron microscope. The image from the microscope is seen by using a computer screen.

BIOLOGY This diatom is a single-celled organism that lives in the water. The image shown above is a dust mite on a piece of fabric.

21st Century Learning To be successful in the 21st century, students need skills and learning experiences that extend beyond subject matter mastery. This project helps students build the following 21st Century Learning: *Creativity and Innovation*; *Communication and Collaboration*; *Information, Media*, and *Technology Literacy*; *Initiative and Self-Direction*; and *Social Skills*.

Pose the following challenge to your students. Your school has invited four different specialists in electron microscope technology to participate in a roundtable discussion during a college fair. The specialists are there to answer questions and convey information about the uses of electron microscopes and the types of careers that utilize this type of technology.

Ask for four student volunteers to be the team of four "experts" in electron microscopy in the following fields: biology, forensics, biochemistry, and food science. The remaining students will form four interview panels. Each panel will select one of the four specialists to interview. The interview panels should prepare a set of questions and their expected answers on the specific uses of electron microscopy in the expert's field, as well as pros and cons of its use. The team of "experts" will prepare a set of expected questions and their answers on which to base their preparation for their roles.

BIOCHEMISTRY A chromosome from the nucleus of a eukaryotic cell

FORENSICS The image on the left is from a light microscope, the image on the right from an SEM. The SEM image shows a clearer image of the fingerprint left on the page because oil from our fingers produces a different intensity of ejected electrons than paper or the ink.

MATERIALS SCIENCE A tip of a pencil is pointing to a tiny pressure sensor (mauve square) used in a car's air bag. When the sensors detect rapid deceleration, they trigger the inflation of the air bag.

Take It Further

1. Infer Why would a forensic investigator want to analyze gunshot residue using an electron microscope?

2. Compare Research the differences between an SEM and a TEM.

Explain

USE VISUALS Have students examine the image of the scientists working with the electron microscope. Point out how a person sees an image made by the electron microscope; the scientists in the photo are not looking into eyepieces, but see a projection on a computer screen. Explain that the type of electron microscope a person uses is typically dependent on the type of information he or she needs to know. A microscope is typically selected based on its resolution, magnification, depth of field, field of view, illumination method, degree of automation, and type of image produced.

Extend

Connect to TECHNOLOGY

Emphasize the time period that the electron microscope was invented and the technology associated with the apparatus. Tell students that cathode ray tubes, magnets, electron beams, and vacuum chambers are all integral parts of the electron microscope. In pairs, have students research other technological advances that came about using the same or similar components. *(Televisions, hand held radios, X-ray machines and lasers all were invented around the same time as the electron microscope and as a result of the same technology.)*

Differentiated Instruction

L1 STRUGGLING STUDENTS Have students draw pictures of an ordinary object as they imagine it would appear under an ordinary microscope and then as they imagine it would appear under an electron microscope.

ELL ENGLISH LANGUAGE LEARNERS Have magnifying glasses available in class, as well as a compound microscope. Allow students time to examine and use both tools.

L3 ADVANCED STUDENTS Assign students to write a summary explaining how an electron microscope provides a far greater degree of magnification and a better resolution than an ordinary compound microscope. Summary should include how Thomson's research on cathode rays propelled electron microscope technology.

Answers

TAKE IT FURTHER

1. An electron microscope would allow scientists to see details in the gunshot residue that might not be visible by other microscopes.
2. An SEM is a scanning electron microscope. In an SEM, an electron beam is passed over the surface of an object. An SEM produces an image of the surface of on an object. A TEM is a transmission electron microscope. In a TEM, an electron beam is directed through an object, producing an image of what is inside an object.

LESSON 4.3

Key Objectives

- **4.3.1 EXPLAIN** what makes elements and isotopes different from each other.
- **4.3.2 EXPLAIN** how isotopes of an element differ.
- **4.3.3 CALCULATE** the atomic mass of an element.

Additional Resources

Reading and Study Workbook, Lesson 4.3

Available Online or on Digital Media:

- Teaching Resources, Lesson 4.3 Review
- Small-Scale Chemistry Manual, Lab 6

PearsonChem.com

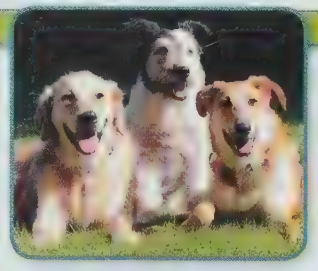
Engage

CHEMISTRY & YOU Direct students to look at the photograph of the dogs and to read the corresponding text. **Ask** What characteristics can you use to classify different dogs? *(Sample answers: height, weight, color, hair length, tail, etc.)* Point out that each dog in the picture is a different variety, called a *breed*, but they are all dogs. Tell students to keep this distinction in mind as they work through the lesson.

Activate Prior Knowledge

Briefly review what students know about subatomic particles and Dalton's atomic theory. Have a student volunteer go to the board, and draw an atom based on the description given by his or her classmates. Have the volunteer label the different parts of the atom with important characteristics, such as charge.

IN ACADEMIC STANDARDS for SCIENCE



- Focus on the development of explanatory models based on their observations during laboratory investigations.
- Explain that the body of scientific knowledge is organized into major theories, which are derived from and supported by the results of many experiments, and allow us to make testable predictions.

C.2.4 Calculate the average atomic mass of an element from its isotopic abundance data.

Also covered C.2.1, C.2.2, C.2.3

4.3 Distinguishing Among Atoms

IN C.2.1 Modern atomic theory: historic development; C.2.2 Subatomic particles and atomic structure; C.2.3 Isotopes, atomic number, and atomic mass; C.2.4 Average atomic mass.

CHEMISTRY & YOU

Q: *How can there be different varieties of atoms?* Some things exist in many different varieties. For example, dogs can differ in many ways, such as color, size, ear shape, and length of hair. Just as there are many types of dogs, atoms come in different varieties, too.

Key Questions

- *What makes one element different from another?*
- *How do isotopes of an element differ?*
- *How do you calculate the atomic mass of an element?*

Vocabulary

- atomic number • mass number
- isotope • atomic mass unit (amu)
- atomic mass

Atomic Number and Mass Number

What makes one element different from another?

Atoms are composed of protons, neutrons, and electrons. Protons and neutrons make up the nucleus. Electrons surround the nucleus. How, then, are atoms of hydrogen, for example, different from atoms of oxygen?

Atomic Number Look at Table 4.2. Notice that a hydrogen atom has one proton, but an oxygen atom has eight protons. **Elements are different because they contain different numbers of protons.** An element's **atomic number** is the number of protons in the nucleus of an atom of that element. Since all hydrogen atoms have one proton, the atomic number of hydrogen is 1. All oxygen atoms have eight protons, so the atomic number of oxygen is 8. The atomic number identifies an element. For each element listed in Table 4.2, the number of protons equals the number of electrons. Remember that atoms are electrically neutral. Thus, the number of electrons (negatively charged particles) must equal the number of protons (positively charged particles).

Table 4.2

Atoms of the First Ten Elements

Name	Symbol	Atomic number	Protons	Neutrons*	Mass number	Electrons
Hydrogen	H	1	1	0	1	1
Helium	He	2	2	2	4	2
Lithium	Li	3	3	4	7	3
Beryllium	Be	4	4	5	9	4
Boron	B	5	5	6	11	5
Carbon	C	6	6	6	12	6
Nitrogen	N	7	7	7	14	7
Oxygen	O	8	8	8	16	8
Fluorine	F	9	9	10	19	9
Neon	Ne	10	10	10	20	10

* Number of neutrons in the most abundant isotope. Isotopes are introduced later in Lesson 4.3.

Focus on ELL

1 CONTENT AND LANGUAGE Direct students' attention to the second paragraph under the Mass Number heading on the following page. Read the second sentence aloud. Explain that this sentence describes a mathematical relationship. Have students identify the words that relate to mathematical symbols. Then demonstrate how to re-write the sentence using these signs to create a word equation. Point out that this technique can be used whenever they are having difficulty understanding similar sentences. Have students practice identifying and re-writing the other descriptions of mathematical relationships in the paragraph.

2 FRONTLOAD THE LESSON Ask students to preview Table 4.2 and the Periodic Table of Elements. Show students how the numbers on the Periodic Table of Elements correspond to the values in Table 4.2.

3 COMPREHENSIBLE INPUT As you write the chemical, use a black marker to write the element symbol, a red marker to represent the protons, and a blue marker to represent the number of electrons. Continue to use the corresponding color throughout the calculation. Use green to represent the neutrons.

SampleProblem 4.1

Understanding Atomic Number

The element nitrogen (N) has an atomic number of 7. How many protons and electrons are in a neutral nitrogen atom?

1 Analyze **Identify the relevant concepts.** The atomic number gives the number of protons, which in a neutral atom equals the number of electrons.

2 Solve **Apply the concepts to this problem.**

Identify the atomic number. Then use the atomic number to find the number of protons and electrons.

The atomic number of nitrogen is 7. So, a neutral nitrogen atom has 7 protons and 7 electrons.

16. How many protons and electrons are in each atom?

- **a.** fluorine (atomic number = 9)
- **b.** calcium (atomic number = 20)
- **c.** aluminum (atomic number = 13)
- **d.** potassium (atomic number = 19)

17. Complete the table.

Element	Atomic number	Protons	Electrons
S	16	a. ___	b. ___
V	c. ___	23	d. ___
e. ___	f. ___	g. ___	5

Mass Number Most of the mass of an atom is concentrated in its nucleus and depends on the number of protons and neutrons. The total number of protons and neutrons in an atom is called the **mass number.** For example, a helium atom has two protons and two neutrons, so its mass number is 4. A carbon atom has six protons and six neutrons, so its mass number is 12.

If you know the atomic number and mass number of an atom of any element, you can determine the atom's composition. The number of neutrons in an atom is the difference between the mass number and atomic number.

Number of neutrons = mass number − atomic number

Table 4.2 shows that a fluorine atom has an atomic number of 9 and a mass number of 19. Since the atomic number equals the number of protons, which equals the number of electrons, a fluorine atom has nine protons and nine electrons. The mass number of fluorine is equal to the number of protons plus the number of neutrons. So the fluorine atom has ten neutrons, which is the difference between the mass number and the atomic number (19 − 9 = 10).

The composition of any atom can be represented in shorthand notation using the atomic number and mass number, as in Figure 4.8. The chemical symbol for gold, Au, appears with two numbers written to its left. The atomic number is the subscript. The mass number is the superscript. You can also refer to atoms by using the mass number and the name of the element. For example, $^{197}_{79}Au$ may be written as gold-197.

Figure 4.8 Chemical Symbol
Au is the chemical symbol for gold.
Apply Concepts *How many electrons does a gold atom have?*

Differentiated Instruction

LPR LESS PROFICIENT READERS Have students make a list of familiar elements and describe at least one real world use for each element. Have students combine their lists into a master list on the chalkboard.

L1 STRUGGLING STUDENTS Have students recreate Table 4.2 in their notebooks, omitting the Neutrons column and the Mass number. Guide students to see the pattern between the atomic number of an element and its corresponding number of protons and electrons.

ELL ENGLISH LANGUAGE LEARNERS Pair students of limited proficiency with more advanced ELL students. Have student pairs create a poster showing how to interpret the superscript and subscript associated with an element. Display the posters in the classroom for reference.

Foundations for Reading

BUILD VOCABULARY Have students use the vocabulary for this section to build a concept map that links and relates the vocabulary terms.

READING STRATEGY Allot time at the beginning of the lesson to remind students how to read a table. Review each table in this lesson, except for the periodic table. Point out that students should read the title, the headings of each row and column, and take note of units. Relate the cells of each table to a matrix or to a spreadsheet. Students need to be able to read the text, locate the appropriate table and extract the necessary information.

Explain

Atomic Number and Mass Number

USE VISUALS Have students look at Table 4.2. Point out that the atomic number is equal to the number of protons for each element. **Ask** Why must the number of electrons equal the number of protons for each element? *(Atoms are electrically neutral.)* **Ask** What is the relationship between the number of protons and the number of neutrons? *(The number of neutrons tends to rise with the number of protons.)*

Sample Practice Problems

A. Identify the element that has 6 protons and 6 neutrons. *(carbon)*

B. What is the atomic number of Lithium (Li)? How many electrons and protons does this element have? *(atomic number = 3, 3 electrons, 3 protons)*

APPLY CONCEPTS Explain that the mass number of an element is defined as the total number of protons and neutrons in the element. Explain that chemists have arbitrarily assigned a value of one atomic mass unit to represent the mass of one twelfth of a carbon-12 atom. **Ask** How do you find the number of neutrons in an atom? *(Subtract the atomic number from the mass number.)*

Answers

FIGURE 4.8: 79 electrons

16. **a.** 9 protons and 9 electrons
b. 20 protons and 20 electrons
c. 13 protons and 13 electrons
d. 19 protons and 19 electrons

17. **a.** 16 **b.** 16 **c.** 23 **d.** 23 **e.** B **f.** 5 **g.** 5

Explain

CHEMISTRY & YOU Atoms of different elements have different numbers of protons. Isotopes of an element have the same number of protons, but different numbers of neutrons.

Misconception Alert

Students are used to seeing subscripts and superscripts in mathematics class. Be sure to emphasize how subscripts and superscripts are used in chemical symbols. When representing elements with shorthand notation, the superscripts and subscripts are located to the left of a chemical element, and the numbers indicate important information about the element.

Sample Practice Problems

A. How many neutrons are in the each atom?

a. $^{40}_{20}Ca$ *(20)* **b.** $^{204}_{81}Te$ *(123)* **c.** $^{127}_{53}I$ *(74)*

B. Use Table 4.2 to express the composition of each atom below in shorthand form.

a. oxygen-16 *($^{16}_{8}O$)* **c.** nitrogen-14 *($^{14}_{7}N$)*

b. helium-4 *($^{4}_{2}He$)*

Explore

Student Activity

PURPOSE To learn about practical applications of isotopes

MATERIALS Library or Internet access

PROCEDURE Have students use the library or Internet to find an isotope of an element that has a practical or everyday use.

EXPECTED OUTCOME Students' research will most likely focus on applications of radioisotopes such as carbon-14 (used in archaeological dating), americium-241 (used in smoke alarms), iodine-131 (used in the treatment of thyroid disorders), and cobalt-60 (used in the treatment of some cancers). Point out that the instability of these isotopes is what makes them useful. Radioisotopes and radioactivity are discussed in Chapter 25.

Sample Problem 4.2

Determining the Composition of an Atom

How many protons, electrons, and neutrons are in each atom?

a. $^{9}_{4}Be$ **b.** $^{20}_{10}Ne$ **c.** $^{23}_{11}Na$

KNOWNS
- Beryllium (Be)
  atomic number = 4
  mass number = 9
- Neon (Ne)
  atomic number = 10
  mass number = 20
- Sodium (Na)
  atomic number = 11
  mass number = 23

UNKNOWNS
number of:
protons = ?
electrons = ?
neutrons = ?

1 Analyze **List the knowns and the unknowns.** Use the definitions of atomic number and mass number to calculate the numbers of protons, electrons, and neutrons.

2 Calculate **Solve for the unknowns.**

Use the atomic number to find the number of protons.

atomic number = number of protons
a. 4 **b.** 10 **c.** 11

Use the atomic number to find the number of electrons.

atomic number = number of electrons
a. 4 **b.** 10 **c.** 11

Use the mass number and atomic number to find the number of neutrons.

number of neutrons = mass number − atomic number
a. number of neutrons = 9 − 4 = 5
b. number of neutrons = 20 − 10 = 10
c. number of neutrons = 23 − 11 = 12

3 Evaluate **Do the results make sense?** For each atom, the mass number equals the number of protons plus the number of neutrons. The results make sense.

18. How many neutrons are in each atom?

a. $^{80}_{35}Br$ **b.** $^{32}_{16}S$ **c.** $^{108}_{47}Ag$ **d.** $^{207}_{82}Pb$

19. Use Table 4.2 to express the composition of each atom below in shorthand form.

a. carbon-12 **c.** beryllium-9
b. boron-11 **d.** oxygen-16

CHEMISTRY & YOU

Q: *How are atoms of one element different from the atoms of another element? How are isotopes of the same element different?*

Isotopes

How do isotopes of an element differ?

Figure 4.9 shows that there are three different kinds of neon atoms. How do these atoms differ? All have the same number of protons (10) and electrons (10), but they each have different numbers of neutrons. **Isotopes** are atoms that have the same number of protons but different numbers of neutrons. **Because isotopes of an element have different numbers of neutrons, they also have different mass numbers.** Despite these differences, isotopes are chemically alike because they have identical numbers of protons and electrons, which are the subatomic particles responsible for chemical behavior. Remember the dogs at the beginning of the lesson. Their color or size doesn't change the fact that they are all dogs. Similarly, the number of neutrons in isotopes of an element doesn't change which element it is because the atomic number doesn't change.

UbD Check for Understanding

The Essential Question **How are atoms of one element different from atoms of another element?**

Have students create an acrostic poem using either *atomic number* or *mass number* that answers this Essential Question. Poems should demonstrate that students understand that the number of protons is a key determinant of difference between elements, but should also make note of differences in numbers of electrons and neutrons, and the fact that most of the atom's mass is concentrated in its nucleus.

ADJUST INSTRUCTION If students are having problems answering the Essential Question, have them review and analyze the differences between the atoms in the elements listed in Table 4.2.

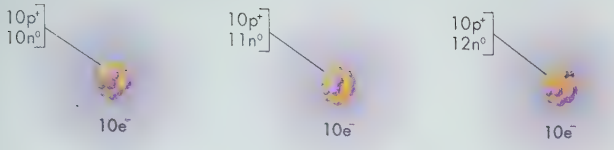


Figure 4.9 Isotopes
Neon-20, neon-21, and neon-22 are three isotopes of neon.
Compare and Contrast *How are these isotopes different? How are they similar?*

Neon-20
10 protons
10 neutrons
10 electrons

Neon-21
10 protons
11 neutrons
10 electrons

Neon-22
10 protons
12 neutrons
10 electrons

There are three known isotopes of hydrogen. Each isotope of hydrogen has one proton in its nucleus. The most common hydrogen isotope has no neutrons. It has a mass number of 1 and is called hydrogen-1 ($^{1}_{1}H$) or hydrogen. The second isotope has one neutron and a mass number of 2. It is called either hydrogen-2 ($^{2}_{1}H$) or deuterium. The third isotope has two neutrons and a mass number of 3. This isotope is called hydrogen-3 ($^{3}_{1}H$) or tritium.

SampleProblem 4.3

Writing Chemical Symbols for Isotopes

Diamonds are a naturally occurring form of elemental carbon. Two stable isotopes of carbon are carbon-12 and carbon-13. Write the symbol for each isotope using superscripts and subscripts to represent the mass number and the atomic number.

1 Analyze **Identify the relevant concepts.** Isotopes are atoms that have the same number of protons but different numbers of neutrons. The composition of an atom can be expressed by writing the chemical symbol, with the atomic number as a subscript and the mass number as a superscript.

2 Solve **Apply the concepts to this problem.**

Use Table 4.2 to identify the symbol and the atomic number for carbon.	The symbol for carbon is *C*. The atomic number of carbon is 6.
Look at the name of the isotope to find the mass number.	For carbon-12, the mass number is 12. For carbon-13, the mass number is 13.
Use the symbol, atomic number, and mass number to write the symbol of the isotope.	For carbon-12, the symbol is $^{12}_{6}C$. For carbon-13, the symbol is $^{13}_{6}C$.

20. Three isotopes of oxygen are oxygen-16, oxygen-17, and oxygen-18. Write the symbol for each, including the atomic number and mass number.

21. Three chromium isotopes are chromium-50, chromium-52, and chromium-53. How many neutrons are in each isotope, given that chromium has an atomic number of 24?

Nuclear Chemistry

Isotopes and nuclides are both similar in the fact that they have negligible effects on the chemical properties of the element. Chemical reactivity depends on the electron structure of an atom, not its nuclear makeup. In nuclear technology, however, the emphasis is on the neutron number because of its drastic effect on the *nuclear properties* of the element. Because neutrons help bind protons together in the nucleus, the ratio of protons to neutrons is a major factor in determining stability. It is not uncommon for a nuclide to be unstable. Isotopes with unstable nuclides are referred to as radioisotopes. In order for these radioisotopes to gain stability, they do not gain or lose electrons, they undergo changes in the nucleus that involve large amounts of energy. This is the stepping stone into nuclear chemistry.

Explain

Isotopes

START A CONVERSATION Explain that isotopes of an atom all have the same number of protons and electrons. **Ask** What do you know about subatomic particles that explains why different isotopes of an atom exhibit almost identical chemical behavior? *(Sample answer: The electrons, not the neutrons, determine the atom's chemical properties.)*

Misconception Alert

Many students associate the term *isotope* with radioactivity. Reinforce the point that an isotope is simply one form of an element. Explain that isotopes can be stable or unstable, and that only unstable isotopes are radioactive. Tell students that they will explore radioactivity and nuclear chemistry in more detail in Chapter 25.

Sample Practice Problems

A. The element cesium has numerous isotopes, including these four: cesium-126, cesium-129, cesium-131, and cesium-132. Given that cesium has an atomic number of 55, how many neutrons are in each of these isotopes? *(71,74, 76, 77)*

B. How does the number of neutrons in carbon-14 differ from the number of neutrons in carbon-12 and carbon-13? *(Carbon-14 has one more neutron than carbon-13, and two more neutrons than carbon-12.)*

Answers

FIGURE 4.9 They have different numbers of neutrons but the same number of protons: hydrogen-1, hydrogen-2, hydrogen-3

18. **a.** 8 **b.** 16 **c.** 61 **d.** 125

19. **a.** $^{12}_{6}C$ **b.** $^{19}_{6}F$ **c.** $^{9}_{6}Be$ **d.** $^{80}_{35}Br$

20. $^{16}_{8}O$, $^{17}_{8}O$, $^{18}_{8}O$

21. Chromium-50 has 26 neutrons; chromium-52 has 28 neutrons; chromium-53 has 29 neutrons.

Explain

Atomic Mass

USE VISUALS Direct students to Table 4.3. Point out that the average atomic masses listed in Table 4.3 are based on the masses of stable isotopes and their percent abundance in Earth's crust. Have students study the average atomic masses in the table. **Ask** Which elements exist predominantly as one natural isotope? *(those with atomic masses closest to a whole number)* **Ask** Which element has substantial amounts of each of its natural isotopes? *(chlorine)*

MAKE A CONNECTION Students may ask why the masses (in amu) of most of the isotopes in Table 4.3 are not whole-number values like the mass numbers that are used to seeing. Explain that although the mass number of carbon-12 exactly equals its mass in amu, this is generally not the case for other isotopes due to the mass defect. Point out that the mass defect is the difference between the mass of a nucleus and the sum of the masses of its component protons and neutrons.

Mass defect also varies with different elements. As a result the masses of isotopes other than carbon-12 in amu (a unit based on the mass of a carbon-12 atom) will generally not be whole numbers. For example, the mass of hydrogen-2 is 2.0141 amu; the mass of oxygen-16 is 15.995 amu. (*NOTE:* Assessment problem 79 asks students to calculate the mass defect of an atom in grams by comparing the actual mass of the atom to the sum of the masses of the atom's component protons, neutrons, and electrons.)

Atomic Mass

How do you calculate the atomic mass of an element?

A glance back at Table 4.1 on page 107 shows that the actual mass of a proton or a neutron is very small (1.67×10^{-24} g). The mass of an electron is 9.11×10^{-28} g, which is negligible in comparison. Given these values, the mass of even the largest atom is incredibly small. Since the 1920s, it has been possible to determine these tiny masses by using a mass spectrometer. With this instrument, the mass of a fluorine atom was found to be 3.155×10^{-23} g, and the mass of an arsenic atom was found to be 1.244×10^{-22} g. Such data about the actual masses of individual atoms can provide useful information, but in general, these values are inconveniently small and impractical to work with. Instead, it is more useful to compare the relative masses of atoms using a reference isotope as a standard. The reference isotope chosen is carbon-12. This isotope of carbon has been assigned a mass of exactly 12 atomic mass units. An **atomic mass unit (amu)** is defined as one twelfth of the mass of a carbon-12 atom. Using these units, a helium-4 atom has one third the mass of a carbon-12 atom. On the other hand, a nickel-60 atom has five times the mass of a carbon-12 atom.

Interpret Data

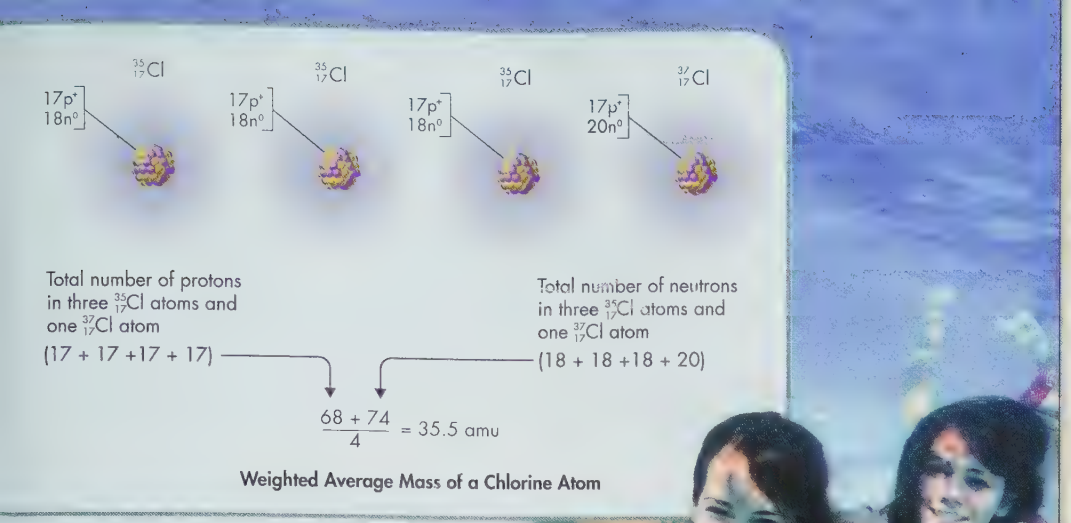
Natural Percent Abundance of Stable Isotopes of Some Elements

Name	Symbol	Natural percent abundance	Mass (amu)	Atomic mass
Hydrogen	$^{1}_{1}H$	99.985	1.0078	1.0079
	$^{2}_{1}H$	0.015	2.0141	
	$^{3}_{1}H$	negligible	3.0160	
Helium	$^{3}_{2}He$	0.0001	3.0160	4.0026
	$^{4}_{2}He$	99.9999	4.0026	
Carbon	$^{12}_{6}C$	98.89	12.000	12.011
	$^{13}_{6}C$	1.11	13.003	
Nitrogen	$^{14}_{7}N$	99.63	14.003	14.007
	$^{15}_{7}N$	0.37	15.000	
Oxygen	$^{16}_{8}O$	99.759	15.995	15.999
	$^{17}_{8}O$	0.037	16.995	
	$^{18}_{8}O$	0.204	17.999	
Sulfur	$^{32}_{16}S$	95.002	31.972	32.06
	$^{33}_{16}S$	0.76	32.971	
	$^{34}_{16}S$	4.22	33.967	
	$^{36}_{16}S$	0.014	35.967	
Chlorine	$^{35}_{17}Cl$	75.77	34.969	35.453
	$^{37}_{17}Cl$	24.23	36.966	

Table 4.3 The atomic mass of an element is calculated using the percent abundance and mass of its isotopes.

a. Identify Which isotope of oxygen is the most abundant?

b. Describe How could you use the atomic mass of helium to determine which isotope of helium is most abundant?



Hint: The natural percent abundance of hydrogen-3 is "negligible" because the amount of naturally occurring hydrogen-3 is so small that it doesn't affect the atomic mass of hydrogen.

UbD Check for Understanding

How do you calculate the atomic mass of an element?

To assess students' understanding of atomic mass, ask students to write a few sentences, create an example, or write a step-by-step explanation of how to determine the atomic mass of an element. Students' products should indicate an understanding of how the natural abundance of each isotope affects the atomic weight of an element.

ADJUST INSTRUCTION To reinforce this concept, perform a probability experiment in your class. Survey 10 students in your class. Ask them to select one sandwich from tuna, turkey, or jelly, one fruit from apple or pear, and one drink from milk or water. Tally the results and create a weighted probability tree diagram. Point out how each selection of the tree is weighted. Show students how this is similar to understanding weighted average mass.

A carbon-12 atom has six protons and six neutrons in its nucleus, and its mass is set as 12 amu. The six protons and six neutrons account for nearly all of this mass. Therefore, the mass of a single proton or a single neutron is about one twelfth of 12 amu, or about 1 amu. Because the mass of any single atom depends mainly on the number of protons and neutrons in the nucleus of the atom, you might predict that the atomic mass of an element should be a whole number. However, that is not usually the case.

In nature, most elements occur as a mixture of two or more isotopes. Each isotope of an element has a fixed mass and a natural percent abundance. Consider the three isotopes of hydrogen discussed earlier in this section. According to Table 4.3, almost all naturally occurring hydrogen (99.985 percent) is hydrogen-1. The other two isotopes are present in trace amounts. Notice that the atomic mass of hydrogen listed in Table 4.3 (1.0079 amu) is very close to the mass of hydrogen-1 (1.0078 amu). The slight difference takes into account the larger masses, but much smaller amounts, of the other two isotopes of hydrogen.

Now consider the two stable isotopes of chlorine listed in Table 4.3: chlorine-35 and chlorine-37. If you calculate the arithmetic mean of these two masses ((34.969 amu + 36.966 amu)/2), you get an average atomic mass of 35.968 amu. However, this value is higher than the actual value of 35.453. To explain this difference, you need to know the natural percent abundance of the isotopes of chlorine. Chlorine-35 accounts for 75 percent of the naturally occurring chlorine atoms; chlorine-37 accounts for only 25 percent. See Figure 4.10. The **atomic mass** of an element is a weighted average mass of the atoms in a naturally occurring sample of the element. A weighted average mass reflects both the mass and the relative abundance of the isotopes as they occur in nature.

Figure 4.10 Isotopes of Chlorine
Chlorine is a reactive element used to disinfect swimming pools. Chlorine occurs as two isotopes: chlorine-35 and chlorine-37. Because there is more chlorine-35 than chlorine-37 in nature, the atomic mass of chlorine, 35.453 amu, is closer to 35 than to 37.
Evaluate ***How does a weighted average differ from an arithmetic mean?***

Carbon-14 Dating

All living organisms contain carbon-12 and carbon-14 in a fixed ratio. After an organism dies, this ratio changes as the carbon-14 decays. Paleontologists and archaeologists use this fact to establish the age of fossils and ancient artifacts.

USE VISUALS Direct students to Figure 4.10. Explain that atomic mass is the weighted average mass of the atoms in a naturally occurring sample of the element. Relate students' knowledge of calculating the mean of a data set or calculating weighted probability to help them understand how this concept is related to chemistry.

Answers

TABLE 4.3

a. oxygen-16

b. Helium has two isotopes, helium-3 and helium-4. The atomic mass of helium is very close to 4 amu, therefore helium-4 must be most abundant.

FIGURE 4.10 In an arithmetic mean, all the numbers in the calculation are weighted equally. A weighted average takes into account the varying weights of the numbers in the data set.

Explain

MAKE A CONNECTION Explain to the class that some teachers evaluate a student's performance based on the weighted average for different work. For example, homework and quizzes might be worth 20%, a term paper might be worth 30%, and an exam might be worth 50%. Have students calculate a grade for a student who receives an 84 on homework and quizzes, a 79 on the term paper, and an 86 on the exam. *(The student would receive a final grade of 83.5 for the grading period.)* Then, explain your own weighting strategy for grading, and have students identify which items have the most influence over the grade that appears on their grade reports.

Sample Practice Problem

Argon has three isotopes with mass numbers 36, 38, and 40, respectively. Which of these isotopes is the most abundant? *(argon-40)*

SampleProblem 4.4

Understanding Relative Abundance of Isotopes

The atomic mass of copper is 63.546 amu. Which of copper's two isotopes is more abundant: copper-63 or copper-65?

1 Analyze Identify the relevant concepts. The atomic mass of an element is the weighted average mass of the atoms in a naturally occurring sample of the element.

2 Solve Apply the concepts to this problem.

Compare the atomic mass to the mass of each isotope.

The atomic mass of 63.546 amu is closer to 63 than it is to 65.

Determine the most abundant isotope based on which isotope's mass is closest to the atomic mass.

Because the atomic mass is a weighted average of the isotopes, copper-63 must be more abundant than copper-65.

22. Boron has two isotopes: boron-10 and boron-11. Which is more abundant, given that the atomic mass of boron is 10.81 amu?

23. There are three isotopes of silicon; they have mass numbers of 28, 29, and 30. The atomic mass of silicon is 28.086 amu. Comment on the relative abundance of these three isotopes.

Now that you know that the atomic mass of an element is a weighted average of the masses of its isotopes, you can determine atomic mass based on relative abundance. To do this, you must know three things: the number of stable isotopes of the element, the mass of each isotope, and the natural percent abundance of each isotope. **To calculate the atomic mass of an element, multiply the mass of each isotope by its natural abundance, expressed as a decimal, and then add the products.** The resulting sum is the weighted average mass of the atoms of the element as they occur in nature. You can calculate the atomic masses listed in Table 4.3 based on the given masses and natural abundances of the isotopes for each element.

For example, carbon has two stable isotopes: carbon-12, which has a natural abundance of 98.89 percent, and carbon-13, which has a natural abundance of 1.11 percent. The mass of carbon-12 is 12.000 amu; the mass of carbon-13 is 13.003 amu. The atomic mass of carbon is calculated as follows:

$$\text{Atomic mass of carbon} = (12.000\ \text{amu} \times 0.9889) + (13.003\ \text{amu} \times 0.0111)$$
$$= (11.867\ \text{amu}) + (0.144\ \text{amu})$$
$$= 12.011\ \text{amu}$$

Foundations for Math

PERCENTAGES Tell students they will need to have a basic understanding of percents in order to calculate atomic mass. Atomic mass is a weighted average that takes into account natural percent abundance.

In **Sample Problem 4.5,** show students that the values given for natural abundance total 100%. In order to use these values to correctly calculate the atomic mass, remind students how to convert a percent to a decimal. Tell students to check the reasonableness of their answer by comparing it to the mass of the isotopes. The atomic mass of the element should be close to the mass of the isotope with the greatest percent of abundance.

Sample Problem 4.5

Calculating Atomic Mass

Element X has two naturally occurring isotopes. The isotope with a mass of 10.012 amu (^{10}X) has a relative abundance of 19.91 percent. The isotope with a mass of 11.009 amu (^{11}X) has a relative abundance of 80.09 percent. Calculate the atomic mass of element X.

To find all the knowns, change the percent abundance to decimals. A percent is a shorthand way of expressing a fraction whose denominator is 100. 19.91% is equivalent to 19.91/100 or 0.1991.

KNOWNS
- isotope ^{10}X:
  mass = 10.012 amu
  relative abundance = 19.91% = 0.1991
- isotope ^{11}X:
  mass = 11.009 amu
  relative abundance = 80.09% = 0.8009

UNKNOWN
atomic mass of X = ?

1 Analyze **List the knowns and the unknown.** The mass each isotope contributes to the element's atomic mass can be calculated by multiplying the isotope's mass by its relative abundance. The atomic mass of the element is the sum of these products.

2 Calculate **Solve for the unknown.**

Use the atomic mass and the decimal form of the percent abundance to the find the mass contributed by each isotope.

for ^{10}X: 10.012 amu × 0.1991 = 1.993 amu
for ^{11}X: 11.009 amu × 0.8009 = 8.817 amu

Add the atomic mass contributions for all the isotopes.

For element X, atomic mass = 1.993 amu + 8.817 amu
= 10.810 amu

3 Evaluate **Does the result make sense?** The calculated value is closer to the mass of the more abundant isotope, as would be expected.

24. The element copper has naturally occurring isotopes with mass numbers of 63 and 65. The relative abundance and atomic masses are 69.2% for mass = 62.93 amu, and 30.8% for mass = 64.93 amu. Calculate the average atomic mass of copper.

25. Calculate the atomic mass of bromine. The two isotopes of bromine have atomic masses and relative abundance of 78.92 amu (50.69%) and 80.92 amu (49.31%).

4.3 LessonCheck

26. Explain What distinguishes the atoms of one element from the atoms of another?

27. Compare and Contrast How do the isotopes of a given element differ from one another?

28. Explain How is atomic mass calculated?

29. Identify What equation tells you how to calculate the number of neutrons in an atom?

30. Compare How is atomic number different from mass number?

31. Use Models What does the number represent in the isotope platinum-194?

32. Explain The atomic masses of elements are generally not whole numbers. Explain why.

33. Identify Which of argon's three isotopes is most abundant: argon-36, argon-38, or argon-40? (*Hint:* the atomic mass of argon is 39.948 amu.)

34. Calculate List the number of protons, neutrons, and electrons in each pair of isotopes.
a. $^{6}_{3}$Li, $^{7}_{3}$Li **b.** $^{42}_{20}$Ca, $^{44}_{10}$Ca **c.** $^{78}_{34}$Se, $^{80}_{34}$Se

Lesson Check Answers

26. Atoms of different elements contain different numbers of protons.

27. mass number − atomic number = number of neutrons

28. They have different mass numbers and different numbers of neutrons.

29. For each isotope, multiply its atomic mass by its percent abundance, then add the products.

30. It allows you to compare the properties of the elements.

31. Mass number, $^{194}_{78}$Pt

32. The atomic mass is the weighted average of the masses of its isotopes.

33. **a.** lithium-6: 3 p^+, 3 e^-, 3 n^0; lithium-7: 3 p^+, 3 e^-, 4 n^0

b. calcium-42: 20 p^+, 20 e^-, 22 n^0; calcium-44: 20 p^+, 20 e^-, 24 n^0

c. selenium-78: 34 p^+, 34 e^-, 44 n^0; selenium-80: 34 p^+, 34 e^-, 46 n^0

34. any two: beryllium (Be), magnesium (Mg), strontium (Sr), barium (Ba), radium (Ra)

Sample Practice Problem

The element antimony (Sb) has naturally occurring isotopes with mass numbers of 121 and 123. The relative abundance and atomic masses are 57.21% for mass = 120.90 amu, and 42.79% for mass = 122.90 amu. Calculate the atomic mass of antimony. *(121.76 amu)*

Evaluate

Informal Assessment

Write the symbols for isotopes of an element not described in the chapter. **Ask** How does changing the value of the subscript change the chemical properties of the atom? *(The subscript designates the number of protons in the atoms of that isotope. Changing the number of protons would change the chemical identity of the isotope to that of another element.)* Then have students complete the 4.3 Lesson Check.

Reteach

Review the concept of weighted averages. Work through the following calculations. If 75% of chlorine atoms are ^{35}Cl species and 25% are ^{37}Cl species, this implies that for a sample of 100 atoms, 75 atoms are ^{35}Cl and 25 atoms are ^{37}Cl species. The combined masses of these atoms would be (75 × 35 amu) + (25 × 37 amu) = 3550 amu for 100 atoms, or 35.5 amu for one atom.

Answers

22. boron-11

23. Silicon-28 must be by far the most abundant. The other two isotopes must be present in very small amounts.

24. 63.6 amu

25. 79.91 amu

SMALL-SCALE LAB

Explore

PURPOSE Students make measurements to calculate the relative abundances of three types of candy in a mixture and use their data to calculate the atomic mass of a candium particle.

MATERIALS mass balance, coated candies (3 different brands), small plastic cups or containers

ADVANCE PREP Prepare in advance a large mixture of the three candies and half fill a clean 3.5-ounce plastic cup for each student. Each sample will contain about 50 total pieces.

SAFETY Discourage students from eating the candies after the experiment. Contamination can easily occur in a lab even if you have taken every precaution to keep the candy free of contamination.

TEACHING TIPS This lab is similar to the longer Small-Scale Lab "Isotopes and Atomic Mass" found in the Small-Scale Chemistry Laboratory Manual.

EXPECTED OUTCOME Sample data are listed below.

Total Mass: 13.16 g; 13.83 g; 15.40 g; 42.39 g (total).

Number: 15; 13; 20; 48 (total).

Average mass (grams): 0.8773 g; 1.064 g; 0.7700 g; 0.8831 g (total).

Relative abundance: 0.3125; 0.2708; 0.4167; 1.000 (total).

Percent abundance: 31.25%; 27.08%; 41.67%; 100% (total).

Relative mass: 0.2742 g; 0.2883 g; 0.3208 g; 0.8833 g (total).

ANALYZE

1–5. See Expected Outcome.

6. Percent abundance is parts per hundred. Relative abundance is parts per one, or the decimal form of percent. The individual percent abundances add up to 100. The individual relative abundances add up to 1.

7. Relative abundance tells you the decimal fraction of particles.

8. The total in row 3 is an average that ignores the relative abundances of particles. The total in row 6 is a weighted average that best represents atomic mass because it considers differences in mass and abundance among the particles.

9. Another student might not have had the same relative abundance of each candy.

YOU'RE THE CHEMIST

1. Any differences are probably due to small variations in the numbers of each kind of candy in the samples, which affects the relative abundances.

2. The larger the samples, the better the results with any of the methods. Mass is likely to provide better results than volume.

Small-Scale Lab

The Atomic Mass of "Candium"

Purpose

To analyze the isotopes of "candium" and to calculate its atomic mass

Materials

- sample of candium
- balance

Procedure

Obtain a sample of "candium" that contains three different brands of round, coated candy. Treat each brand of candy as an isotope of candium. Separate the three isotopes into groups labeled A, B, and C, and measure the mass of each isotope. Count the number of atoms in each sample. Make a table similar to the one below to record your measured and calculated data.

	A	B	C	Totals
Total mass (grams)				
Number				
Average mass (grams)				
Relative abundance				
Percent abundance				
Relative mass				

Analyze

Using the experimental data, record the answers to the following questions below your data table.

1. Calculate Calculate the average mass of each isotope by dividing its total mass by the number of particles of that isotope.

2. Calculate Calculate the relative abundance of each isotope by dividing its number of particles by the total number of particles.

3. Calculate Calculate the percent abundance of each isotope by multiplying the relative abundance from Step 2 by 100.

4. Calculate Calculate the relative mass of each isotope by multiplying its relative abundance from Step 2 by its average mass.

5. Calculate Calculate the weighted average mass of all candium particles by adding the relative masses. This weighted average mass is the atomic mass of candium.

6. Explain What is the difference between percent abundance and relative abundance? What is the result when you total the individual relative abundances? The individual percent abundances?

7. Identify The percent abundance of each kind of candy tells you how many of each kind of candy there are in every 100 particles. What does relative abundance tell you?

8. Analyze Data Compare the total values for rows 3 and 6 in the table. Explain why the totals differ and why the value in row 6 best represents atomic mass.

9. Analyze Data Explain any differences between the atomic mass of your candium sample and that of your neighbor. Explain why the difference would be smaller if larger samples were used.

You're the Chemist

The following small-scale activity allows you to develop your own procedures and analyze the results.

1. Analyze Data Determine the atomic mass of a second sample of candium. How does it compare with the first? Suggest reasons for any differences between the samples.

Focus on ELL

4 LANGUAGE PRODUCTION Have students work in groups of three to complete the lab. Make sure each group has ELLs of varied language proficiencies, so that more proficient students can help less proficient ones. Have students work according to their proficiency level.

BEGINNING: LOW/HIGH Paraphrase the procedural steps and group students with higher language proficiency partners.

INTERMEDIATE: LOW/HIGH Have students brainstorm what they think they may observe, prior to performing each step. Allow students to orally present their results.

ADVANCED: LOW/HIGH Have students write a bulleted list stating the procedure, their findings, and their conclusions.

4 Study Guide

BIG IDEA ELECTRONS AND THE STRUCTURE OF ATOMS

Atoms are the smallest particles of an element that still have the chemical properties of that element. Atoms have positively charged protons and neutral neutrons inside a nucleus, and negatively charged electrons outside the nucleus. Atoms of the same element have the same number of protons, which is equal to an atom's atomic number. But atoms of the same element can have different numbers of neutrons. Atoms of the same element with different numbers of neutrons are isotopes.

4.1 Defining the Atom

- Democritus reasoned that atoms were indivisible and indestructible. By using experimental methods, Dalton transformed Democritus's ideas on atoms into a scientific theory.
- Scientists can observe individual atoms by using instruments such as scanning electron microscopes.

- atom (102)
- Dalton's atomic theory (103)

4.2 Structure of the Nuclear Atom

- Three kinds of subatomic particles are electrons, protons, and neutrons.
- In the nuclear atom, the protons and neutrons are located in the nucleus. The electrons are distributed around the nucleus and occupy almost all the volume of the atom.

- electron (105)
- cathode ray (105)
- proton (107)
- neutron (107)
- nucleus (108)

4.3 Distinguishing Among Atoms

- Elements are different because they contain different numbers of protons.
- Because isotopes of an element have different numbers of neutrons, they also have different mass numbers.
- To calculate the atomic mass of an element, multiply the mass of each isotope by its natural abundance, expressed as a decimal, and then add the products.

- atomic number (112)
- mass number (113)
- isotope (114)
- atomic mass unit (amu) (116)
- atomic mass (117)

Key Equation

$$\text{number of neutrons} = \text{mass number} - \text{atomic number}$$

Evaluate

Review and Assessment Resources

WALK-THRU TUTORIALS Sample Problems 4.1 and 4.2 have animated step-by-step tutorials that explains the problem-solving strategy in detail.

PROBLEM SETS Have students practice more problems using the Chapter 4 Online Problem Set.

MATH SKILLS Have struggling students practice manipulating algebraic equations using the MathXL learning module.

VIRTUAL LABS Have students complete a virtual lab as an in-class or take home assignment to help reinforce their understanding of atomic structure. To investigate the discovery of the electron and its negative charge, assign the labs Thomson Cathode Ray Tube Experiment and Millikan Oil Drop Experiment. Students can study the procedures Rutherford used to disprove the plum pudding model of the atom in Atomic Structure: Rutherford's Experiment.

Study Tip

ORGANIZE NEW INFORMATION Tell students: Use a reading strategy that you practiced in this chapter to organize the subject matter in a way that helps you study. For example, if you have trouble remembering all the new vocabulary, try listing the new terms and defining them in your own words.

UbD Performance Tasks

IT'S "ELEMENT"ARY: Have students choose three different elements from the Periodic Table of Elements. For each element, ask students to do the following: write the shorthand version of the element, determine the atomic number, the number of protons, the number of electrons, and the number of neutrons. Then have students calculate the atomic mass and identify two isotopes of each element, if possible. Finally, ask students to compare their elements with a partner. Students can present their information on a poster, slide show, or as a pamphlet.

SHOWING IN 3D: Create a three dimensional model of one of the elements on Periodic Table of Elements. The number of protons, neutrons, and electrons should be clearly represented. Use the model to demonstrate two different isotopes of the element. Present the model to class and explain how to determine the atomic weight.

ASSESSMENT

Evaluate

ANSWERS

LESSON 4.1

35. The smallest particle of an element that still has the properties of that element.

36. Democritus's ideas were not helpful in explaining chemical behavior because they lacked experimental support.

37. Dalton would agree with all four statements because they all fit his atomic theory.

38. The atoms are separated, joined, and rearranged.

LESSON 4.2

39. **a.** A beam of electrons (cathode rays) is deflected by an electric field toward the positively charged plate.

b. The cathode rays were always composed of electrons regardless of the metal used in the electrodes or the gas used in the cathode-ray tube.

40. repel

41. The mass of the proton and neutron are equal; protons are positively charged and neutrons are neutral.

42. Atoms are neutral: number of protons = number of electrons. Loss of an electron means that the number of p^+ is greater than the number of e^-, so the remaining particle is positively charged.

43. The electrons were stuck in a lump of positive charge.

44. He did not expect alpha particles to be deflected at a large angle.

45. positive

46. protons and neutrons (Rutherford suspected there was something in the nucleus in addition to protons—but didn't know them as neutrons.)

LESSON 4.3

47. It has equal numbers of positively-charged protons and negatively-charged electrons.

48. the number of protons in the nucleus

49. **a.** 15 **b.** 42 **c.** 13 **d.** 48 **e.** 24 **f.** 82

50. The atomic number is the number of protons. The mass number is the sum of the protons and neutrons.

51. **a.** 19 **b.** 9 **c.** 14 **d.** 29 **e.** 22 **f.** 22 **g.** 25 **h.** 30

52. mass numbers, atomic masses, number of neutrons, relative abundance

53. 6.941

4 Assessment

* Solutions appear in Appendix E

Lesson by Lesson

4.1 Defining the Atom

35. What is an atom?

36. What were the limitations of Democritus's ideas about atoms?

37. With which of these statements would John Dalton have agreed in the early 1800s? For each, explain why or why not.

a. Atoms are the smallest particles of matter.
b. The mass of an iron atom is different from the mass of a copper atom.
c. Every atom of silver is identical to every other atom of silver.
d. A compound is composed of atoms of two or more different elements.

38. Use Dalton's atomic theory to describe how atoms interact during a chemical reaction.

4.2 Structure of the Nuclear Atom

39. What experimental evidence did Thomson have for each statement?

a. Electrons have a negative charge.
b. Atoms of all elements contain electrons.

***40.** Would you expect two electrons to attract or repel each other?

41. How do the charge and mass of a neutron compare to the charge and mass of a proton?

42. Why does it make sense that if an atom loses electrons, it is left with a positive charge?

43. Describe the location of the electrons in Thomson's "plum-pudding" model of the atom.

***44.** How did the results of Rutherford's gold-foil experiment differ from his expectations?

45. What is the charge, positive or negative, of the nucleus of every atom?

46. In the Rutherford atomic model, which subatomic particles are located in the nucleus?

4.3 Distinguishing Among Atoms

47. Why is an atom electrically neutral?

48. What does the atomic number of each atom represent?

49. How many protons are in the nuclei of the following atoms?

a. phosphorus (P) **d.** cadmium (Cd)
b. molybdenum (Mo) **e.** chromium (Cr)
c. aluminum (Al) **f.** lead (Pb)

50. What is the difference between the mass number and the atomic number of an atom?

***51.** Complete the following table.

Atomic number	Mass number	Number of protons	Number of neutrons
9	a. ____	b. ____	10
c. ____	d. ____	14	15
e. ____	47	f. ____	25
g. ____	55	25	h. ____

52. Name two ways that isotopes of an element differ.

***53.** Lithium has two isotopes, lithium-6 (atomic mass = 6.015, relative abundance = 7.5%) and lithium-7 (atomic mass = 7.016, relative abundance = 92.5%). Calculate the atomic mass of lithium.

Understand Concepts

***54.** How can there be more than 1000 different atoms when there are only about 100 different elements?

55. What data must you know about the isotopes of an element to calculate the atomic mass of the element?

56. How is an average mass different from a weighted average mass?

57. What is the atomic mass of an element?

58. Characterize the size of an atom.

59. Compare the size and density of an atom with its nucleus.

***60.** You are standing on the top of a boron-11 nucleus. Describe the numbers and kinds of subatomic particles you see looking down into the nucleus, and those you see looking out from the nucleus.

UNDERSTAND CONCEPTS

54. because of the existence of isotopes

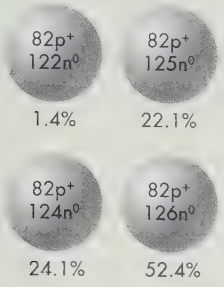
55. which isotopes exist, their masses, and their natural percent abundance

56. Average atomic mass is the arithmetic mean of the isotopes. Weighted average atomic mass considers both the mass and the relative abundance of the isotopes.

57. The atomic mass is the weighted average of the masses of all the isotopes.

58. very, very tiny—but larger than protons and electrons

59. The nucleus is very small and very dense compared with the atom.



60. 5 protons and 6 neutrons in the nucleus; 5 electrons outside the nucleus

61. What parts of Dalton's atomic theory no longer agree with the current picture of the atom?

62. Millikan measured the quantity of charge carried by an electron. How did he then calculate the mass of an electron?

63. How is the atomic mass of an element calculated from isotope data?

*64. The four isotopes of lead are shown below, each with its percent by mass abundance and the composition of its nucleus. Using these data, calculate the approximate atomic mass of lead.

65. Dalton's atomic theory was not correct in every detail. Should this be taken as a criticism of Dalton as a scientist? Explain.

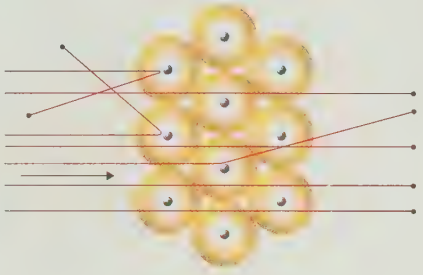
*66. The following table shows some of the data collected by Rutherford and his colleagues during their gold-foil experiment.

Angle of deflection (degrees)	Number of deflections
5	8,289,000
10	502,570
15	120,570
30	7800
45	1435
60	477
75	211
>105	198

a. What percentage of the alpha particle deflections were 5° or less?
b. What percentage of the deflections were 15° or less?
c. What percentage of the deflections were 60° or greater?

*67. Using the data for nitrogen listed in Table 4.3, calculate the weighted average atomic mass of nitrogen. Show your work.

68. What characteristics of cathode rays led Thomson to conclude that the rays consisted of negatively charged particles?



69. If you know the atomic number and mass number of an atom of an element, how can you determine the number of protons, neutrons, and electrons in that atom?

70. What makes isotopes of the same element chemically alike?

71. If isotopes are chemically alike, but physically different, propose which subatomic particles are responsible for determining an element's chemical reactivity.

Think Critically

72. **Interpret Diagrams** The diagram below shows gold atoms being bombarded with fast-moving alpha particles.

a. The large yellow spheres represent gold atoms. What do the small gray spheres represent?
b. List at least two characteristics of the small gray spheres.
c. Which subatomic particle cannot be found in the area represented by the gray spheres?

73. **Evaluate and Revise** How could you modify Rutherford's experimental procedure to determine the relative sizes of different nuclei?

Focus on ELL

5 ASSESS UNDERSTANDING Create a formative assessment to determine the students' level of mastery of the concepts. If the level is low, reteach the concepts that the students found to be the most difficult.

BEGINNING
LOW Ask students to label a diagram of an atom.
HIGH Ask students to create their own diagram of an atom.

INTERMEDIATE
LOW Paraphrase or reread the directions to the formative assessment.
HIGH Ask students to compare their answers on the formative assessment to a partner's answers. Have them discuss any discrepancies.

ADVANCED: LOW/HIGH Review the formative assessment with students. Have them give you feedback on the topics they understood the best and the topics that they still need help with.

ASSESSMENT

61. All atoms of the same element are not identical (isotopes). The atom is not the smallest particle of matter.

62. He used the quantity of charge value and the charge-to-mass ratio measured by Thomson.

63. The masses of isotopes in a sample of the element are averaged, based on relative abundance. The result is the element's atomic mass.

64. 207 amu

65. No; in general he proposed a valid theory in line with the experimental evidence available to him.

66. **a.** 92.90% **b.** 99.89% **c.** 0.00993%

67. $^{14}_{7}$N: 14.003 amu; 99.63%
$^{15}_{7}$N: 15.000 amu; 0.37%
average atomic mass = 14.01 amu

68. They were attracted to a positively charged plate.

69. Atomic number is the same as the number of protons and electrons; mass number minus atomic number equals number of neutrons.

70. Because they have identical numbers of protons, they also have identical numbers of electrons; electrons are the subatomic particles that are responsible for chemical behavior.

71. protons and electrons

THINK CRITICALLY

72. **a.** the nucleus of an atom;
b. very small volume; almost all the mass of the atom; high density; positive charge;
c. electron

73. Change the metal used as a target and account for differences in deflection patterns.

Explain

CHEMYSTERY

START A CONVERSATION Have students read over the CHEMystery. As a class discuss the findings obtained by the use of the electron microscope. Discuss whether or not students came to this conclusion during the study of this chapter. Have students share what they learned from the activities in the Chemistry and Technology Feature to help other students answer the CHEMystery questions. Have students highlight what they know about electrons and the structure of atoms that can help them to understand what the researchers must have seen in the microscope.

CHEMYSTERY ANSWERS

82. Electron microscopes have a higher resolution than light microscopes so smaller aspects of an object can be differentiated using an electron microscope.

83. **BIG**IDEA The function of the electron microscope is based on the properties of electrons. Without the knowledge of electrons and other subatomic particles, electron microscopes might not have been invented.

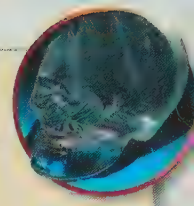
***74.** **Explain** Rutherford's atomic theory proposed a dense nucleus surrounded by very small electrons. This structure implies that atoms are composed mainly of empty space. If all matter is mainly empty space, why is it impossible to walk through walls or pass your hand through your desk?

75. **Explain** This chapter illustrates the scientific method in action. What happens when new experimental results cannot be explained by the existing theory?

76. **Apply Concepts** The law of conservation of mass was introduced in Chapter 2. Use Dalton's atomic theory to explain this law.

77. **Infer** Diamond and graphite are both composed of carbon atoms. The density of diamond is 3.52 g/cm^3. The density of graphite is 2.25 g/cm^3. In 1955, scientists successfully made diamond from graphite. Using the relative densities, consider what happens at the atomic level when this change occurs. Then suggest how this synthesis may have been accomplished.

***78.** **Calculate** Lithium has two naturally occurring isotopes. Lithium-6 has an atomic mass of 6.015 amu; lithium-7 has an atomic mass of 7.016 amu. The atomic mass of lithium is 6.941 amu. What is the percentage of naturally occurring lithium-7?



***79.** **Calculate** When the masses of the particles that make up an atom are added together, the sum is always larger than the actual mass of the atom. The missing mass, called the mass defect, represents the matter converted into energy when the nucleus was formed from its component protons and neutrons. Calculate the mass defect of a chlorine-35 atom by using the data in Table 4.1. The actual mass of a chlorine-35 atom is 5.81 × 10^{-23} g.

Write About Science

80. **Communicate** Explain how Rutherford's gold-foil experiment yielded new evidence about atomic structure. *Hint:* First, describe the setup of the experiment. Then, explain how Rutherford interpreted his experimental data.

81. Connect to the **BIG**IDEA Choose two atoms from Table 4.2. Compare and contrast the structure of the two atoms.

CHEMYSTERY

Artifacts or Artifakes?

There are currently no crystal skulls that have been proven to be from ancient civilizations. The Linnean Society of London is a research institute specializing in taxonomy and natural history. They have used electron microscopy to view the surface of crystal skulls, including a crystal skull that is part of the Smithsonian collection. Images from the scanning electron microscope reveal circular patterns on the surface of the skulls. These patterns indicate the skulls were likely carved using a modern carving device with a rotary wheel. Ancient civilizations would not have had such devices. Therefore, all the crystal skulls that are known today appear to be "artifakes," not artifacts.

82. **Infer** Why would electron microscopes be able to provide more information about an object than a light microscope?

83. Connect to the **BIG**IDEA How has knowledge of atomic structure aided in the development of the electron microscope?

Cumulative Review

84. How does a scientific law differ from a scientific theory?

85. Classify each as an element, a compound, or a mixture.

a. sulfur
b. salad oil
c. newspaper
d. orange

***86.** Oxygen and hydrogen react explosively to form water. In one reaction, 6 g of hydrogen combines with oxygen to form 54 g of water. How much oxygen was used?

87. An aquarium measures 54.0 cm × 31.10 m × 80.0 cm. How many cubic centimeters of water will this aquarium hold?

***88.** What is the mass of 4.42 cm^3 of platinum? The density of platinum is 22.5 g/cm^3.

If You Have Trouble With . . .					
Question	84	85	86	87	88
See Chapter	1	2	2	3	3

Answers

74. The following are reasonable hypotheses: The space in an individual atom is large relative to the volume of the atom, but very small relative to an object the size of a hand. There are many layers of atoms in a wall or a desk. The space that exists is distributed evenly throughout the solid, similar to the distribution of air pockets in foam insulation.

75. The theory must be modified and then retested.

76. In a chemical change, atoms are not created or destroyed; they are rearranged.

77. Because diamond is more dense than graphite, pressure could be used to "squeeze" the carbon atoms closer together.

78. 92.5%

79. 4 × 10^{-25} g

WRITE ABOUT SCIENCE

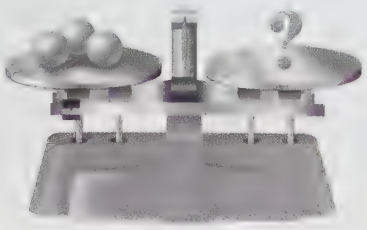
80. In Rutherford's gold-foil experiment, a narrow beam of alpha particles was directed at a very thin sheet of gold foil. Most of the alpha particles passed straight through the gold atoms without being deflected, but a small fraction bounced off the foil at very large angles. To explain his results, Rutherford proposed that an atom is mostly empty space, and that the positive charge and most of the mass of the atom are concentrated in a very small region. Rutherford's experiment yielded evidence of the nucleus, and led to an improved atomic model known as the nuclear atom.

Standardized Test Prep for Indiana

Standards: C.2.2, C.2.3, C.2.4

Select the choice that best answers each question or completes each statement.

1. The smallest particle of an element that retains its identity in a chemical reaction is a
   (A) proton.
   (B) neutron.
   (C) atom.
   (D) compound.



2. Which of these descriptions is *incorrect*?
   (A) proton: positive charge, in nucleus, mass of ≈1 amu
   (B) electron: negative charge, mass of ≈0 amu, in nucleus
   (C) neutron: mass of ≈1 amu, no charge

3. Thallium has two isotopes, thallium-203 and thallium-205. Thallium's atomic number is 81, and its atomic mass is 204.38 amu. Which statement about the thallium isotopes is true?
   (A) There is more thallium-203 in nature.
   (B) Atoms of both isotopes have 81 protons.
   (C) Thallium-205 atoms have fewer neutrons.
   (D) The most common atom of thallium has a mass of 204.38 amu.

4. Which atom is composed of 16 protons, 16 electrons, and 16 neutrons?
   (A) $^{48}_{16}S$ (C) $^{32}_{16}S$
   (B) $^{16}_{32}Ge$ (D) $^{16}_{32}S$

Use the art to answer Question 5.

5. How many nitrogen-14 atoms (^{14}N) would you need to place on the right pan to balance the three calcium-42 atoms (^{42}Ca) on the left pan of the "atomic balance" below? Describe the method you used to determine your answer, including any calculations.

Tips for Success

Connectors Sometimes two phrases in a true/false question are connected by a word such as *because* or *therefore*. These words imply a relationship between one part of the sentence and another. Statements that include such words can be false even if both parts of the statement are true by themselves.

For each question below, there are two statements. Decide whether each statement is true or false. Then decide whether Statement II is a correct explanation for Statement I.

	Statement I		Statement II
6.	Every aluminum-27 atom has 27 protons and 27 electrons.	BECAUSE	The mass number of aluminum-27 is 27.
7.	Isotopes of an element have different atomic masses.	BECAUSE	The nuclei of an element's isotopes contain different numbers of protons.
8.	An electron is repelled by a negatively charged particle.	BECAUSE	An electron has a negative charge.
9.	In an atom, the number of neutrons is generally equal to or greater than the number of protons.	BECAUSE	The mass number is generally equal to or greater than the atomic number.

Materials List

For the Student

Small-Scale Lab, p 149
- cereal box
- diffraction grating
- tape
- ruler
- scissors
- black construction paper
- white notebook paper

Quick Lab, p 142
- Bunsen burner
- 6 small test tubes
- 6 cotton swabs
- 0.1*M* NaCl, 0.5*M* $CaCl_2$, 0.1*M* LiCl, 0.1*M* $CuCl_2$, 0.1*M* KCl, unknown solution

For the Teacher

Teacher Demo, p 129
- a trumpet or trombone
- a player

Teacher Demo, p 130
- three balls: red, blue, and yellow
- step stool with three steps

Teacher Demo, p 131
- three metal or wooden skewers
- three foam balls (3 or 4 inches in diameter)

Class Activity, p 139
- several sealed boxes containing common items such as rubber bands, golf, tennis, or table-tennis balls
- cans of different sizes, and different shapes cut from blocks of wood or foam

Class Activity, p 141
- paper and pencil
- ruler

What's Online

Students access guided step-by-step tutorials for solving various electron configuration and emission problems.

Students can practice key problem-solving skills in an online problem set.

Identify the students that struggle with math by assigning an online math skills diagnostic test. These students can then improve and practice math skills using the MathXL tutorial system.

Students go into a virtual lab tour in which electrons and atoms are studied in a simulated laboratory environment.

Student watch animations of a selected figures from the chapter followed by questions to check for understanding.

Students watch an overview of a key chapter concept using real-world contexts and concrete examples and analogies. Each activity includes an interactive animation followed by analysis questions.

IN ACADEMIC STANDARDS for SCIENCE

Nature of Science

- Recognize that new scientific discoveries often lead to a re-evaluation of previously accepted scientific knowledge and of commonly held ideas.
- Describe how scientific discoveries lead to the development of new technologies, and conversely how technological advances can lead to scientific discoveries through new experimental methods and equipment.

Also covered C.2.1, C.2.2

Focus on ELL

1 CONTENT AND LANGUAGE Begin the class by reviewing the three lesson titles. Focus students' attention on the words *atom, model,* and *electron.* Ask students to recall definitions based on what they learned in chapter 4. Write the words *quantum* and *spectra* on the board. Pair students and have them create a word map for each word, which should include terms, phrases, or drawings that are associated with the word. Have each pair share their word maps with the class.

BEGINNING: LOW/HIGH Write each word on a separate card and create a drawing on the back. Add these words to the word wall.

INTERMEDIATE

LOW Paraphrase the Essential Questions.

HIGH Summarize the CHEMystery story by writing the main idea of the story.

ADVANCED: LOW/HIGH Compare the Essential Questions to the lesson titles. Predict which lessons will contain the answers to the Essential Questions.

BIGIDEA

ELECTRONS AND THE STRUCTURE OF ATOMS

Essential Questions:

1. *How does the quantum mechanical model describe the arrangement of electrons in atoms?*
2. *What happens when electrons in atoms absorb or release energy?*

CHEMYSTERY

Now You See It... Now You Don't

Young Liam loves to go outside at night and gaze at the stars. For his birthday, his parents gave him glow-in-the-dark star stickers so that he could look at the stars from the comfort of his bed.

That night, Liam looked at the constellations he had created on his ceiling while he drifted off to sleep. A few hours later, Liam woke up very disturbed. The stars were no longer glowing even though it was still dark in his room. He turned on his bedroom light and ran down the hall to wake his parents. However, when Liam brought his parents back to his room and turned off the light, the stars were glowing again. Why did the stars cease to glow and then light up again later?

▶ Connect to the BIGIDEA As you read about electrons in atoms, think about how glow-in-the-dark stickers might work.

INDIANA'S ACADEMIC STANDARDS FOR SCIENCE

Atmoic Structure and the Periodic Table C.2.1, C.2.2. See lessons for details.

Introduce the Chapter

CONNECTIONS TO EVERYDAY LANGUAGE Students have probably heard the expression *quantum jump* or *quantum leap*. In everyday language, this expression is often used to describe large and sudden changes. For example, a large and sudden increase in a person's income may be described as a *quantum jump*. Use the activity to introduce students to ideas about quantum effects.

Activity You'll need to identify stairs where students can walk up and down. Have two or three students at a time walk up several steps. Then have students walk back down the steps. **Ask** How was your height above the ground limited by the steps? *(I could only move distances that corresponded to the heights of the steps.)* Explain that the term *quantum jump* in science refers to small, discrete changes in energy. **Ask** How is the scientific meaning of *quantum jump* similar to the everyday use of the term? How is it different? *(Both refer to discrete changes, but the everyday use often refers to large changes, whereas the science use refers to tiny changes.)*

UbD

Understanding by Design

Students are building toward an understanding of atoms by studying the behavior of electrons.

PERFORMANCE GOALS At the end of Chapter 5, students will be able to answer the essential questions by applying their knowledge of the quantum mechanical model of the atom. Students will also be able to calculate the wavelength of light if given its frequency.

ESSENTIAL QUESTIONS Read the essential questions aloud. Explain to students that one of the fundamental ideas of quantum mechanics is describing electron position using probability rather than precise calculation. **Ask** Why do you think we use probability rather than precise calculations? *(We can't precisely calculate the location or speed of an electron.)* **Ask** How do you think electrons in an atom might gain energy? What do you think happens to the energy an electron releases? *(Engage students in a discussion of reasonable answers.)*

BIGIDEA Use the photo of the fireworks to help students connect to the concepts they will learn in this chapter. Activate prior knowledge by having students describe fireworks displays they have seen. Encourage them to describe the different colors and patterns. **Ask** Why do you think the photo of fireworks opens this chapter about electrons and atoms? *(The fireworks display is due to changes in the electron configurations of atoms.)*

CHEMYSTERY Have students read over the CHEMystery. Activate prior knowledge by asking students if they have ever seen glow-in-the-dark stars like those described in the story. **Ask** Did they stop glowing immediately or slowly? *(The light gradually fades away.)* Connect the CHEMystery to the Big Idea of Electrons and the Structure of Atoms by reminding students that light is a form of energy. Have them consider what the gradual decrease in light indicates about the energy of the star stickers. **Ask** What clues in the story indicate why the stars stop glowing and then start glowing again later? *(The stars glow after they have been exposed to light. They stop glowing after the light is turned off.)*

LESSON 5.1

Key Objectives

5.1.1 DESCRIBE what Bohr proposed in his model of the atom.

5.1.2 DESCRIBE what the quantum mechanical model determines about the electrons in an atom.

5.1.3 EXPLAIN how sublevels of principal energy levels differ.

Additional Resources

Reading and Study Workbook, Lesson 5.1
Available Online or on Digital Media:
- Teaching Resources, Lesson 5.1

PearsonChem.com

Engage

CHEMISTRY & YOU Have students read the opening text. Explain that models are often used to represent something that is very large or very small. **Ask** How are models useful? *(You can test a model to see if your ideas or design are correct.)*

Build Background

Compare the use of atomic models to develop the atomic theory to the use of physical or computer-generated models to design, develop, and test cars.

Foundations for Reading

BUILD VOCABULARY Explain that the word *orbital* was coined by scientists to describe the space in which an electron has a high probability of being found. It is derived from the word *orbit*, the path around the nucleus that electrons were thought to follow.

IN ACADEMIC STANDARDS for SCIENCE

- Recognize that new scientific discoveries often lead to a re-evaluation of previously accepted scientific knowledge and of commonly held ideas.

C.2.1 Describe how models of atomic structure changed over time based on available experimental evidence and understand the current model of atomic structure.

C.2.1 Modern atomic theory: historic development; **C.2.2** Subatomic particles and atomic structure

CHEMISTRY & YOU

Q: *Why do scientists use mathematical models to describe the position of electrons in atoms?* Wind tunnels and models are often used to simulate the forces from the moving air on a design. Shown here is a life-sized model of a speed skier. It is a physical model. However, not all models are physical. In fact, the current model of the atom is a mathematical model.

Key Questions

What did Bohr propose in his model of the atom?

What does the quantum mechanical model determine about the electrons in an atom?

How do sublevels of principal energy levels differ?

Vocabulary

- energy level
- quantum
- quantum mechanical model
- atomic orbital

Energy Levels in Atoms

What did Bohr propose in his model of the atom?

Thus far, the atomic model presented in this textbook has considered atoms as consisting of protons and neutrons making up a nucleus surrounded by electrons. After discovering the atomic nucleus, Rutherford used existing ideas about the atom and proposed an atomic model in which the electrons move around the nucleus like the planets move around the sun.

Limitations of Rutherford's Atomic Model Rutherford's atomic model explained only a few simple properties of atoms. It could not explain the chemical properties of elements. For example, Rutherford's model could not explain why metals or compounds of metals give off characteristic colors when heated in a flame. It also could not explain why an object such as the iron scroll shown in Figure 5.1 first glows dull red, then yellow, and then white when heated to higher and higher temperatures. Explaining what leads to the chemical properties of elements required a model that better described the behavior of electrons in atoms.

Figure 5.1 Glowing Metal Rutherford's model failed to explain why objects change color when heated. As the temperature of this iron scroll is increased, it first appears black, then red, then yellow, and then white. The observed behavior could be explained only if the atoms in the iron gave off light in specific amounts of energy. A better atomic model was needed to explain this observation.

Focus on ELL

1 CONTENT AND LANGUAGE Begin the lesson by drawing students' attention to the word *quantum* in the vocabulary list, and have them read the Reading Support feature on page 129. Have students brainstorm the answer to the feature's associated question. Point out that just as a quantity of matter can be measured, so can a quantum of energy.

2 FRONTLOAD THE LESSON Ask students to look at Figure 5.2 and discuss with a partner the differences between the two ladders.

3 COMPREHENSIBLE INPUT Create a compare and contrast chart for students. Have students compare each type of electron model. Encourage students to draw pictures to help them.

The Bohr Model In 1913, Niels Bohr (1885–1962), a young Danish physicist and a student of Rutherford, developed a new atomic model. He changed Rutherford's model to incorporate newer discoveries about how the energy of an atom changes when the atom absorbs or emits light. He considered the simplest atom, hydrogen, which has one electron. **Bohr proposed that an electron is found only in specific circular paths, or orbits, around the nucleus.**

Each possible electron orbit in Bohr's model has a fixed energy. The fixed energies an electron can have are called **energy levels.** The fixed energy levels of electrons are somewhat like the rungs of the ladder in Figure 5.2a. The lowest rung of the ladder corresponds to the lowest energy level. A person can climb up or down the ladder by stepping from rung to rung. Similarly, an electron can move from one energy level to another. A person on the ladder cannot stand between the rungs. Similarly, the electrons in an atom cannot exist between energy levels. To move from one rung to another, a person climbing the ladder must move just the right distance. To move from one energy level to another, an electron must gain or lose just the right amount of energy. A **quantum** of energy is the amount of energy required to move an electron from one energy level to another energy level. The energy of an electron is therefore said to be quantized.

READING SUPPORT

Build Vocabulary: *Latin Word Origins* *Quantum* comes from the Latin word *quantus*, meaning "how much." ***What other commonly used English word comes from this root?***

Figure 5.2 Energy Levels
The rungs of a ladder are somewhat like the energy levels in Bohr's model of the atom. **a.** In an ordinary ladder, the rungs are equally spaced. **b.** The energy levels in atoms are unequally spaced, like the rungs in this unusual ladder. The higher energy levels are closer together.
Compare *For the ladder in* **b**, *compare the amount of energy it would take to move from the first rung to the second rung with the amount of energy it would take to move from the second rung to the third rung.*

The amount of energy an electron gains or loses in an atom is not always the same. Like the rungs of the strange ladder in Figure 5.2b, the energy levels in an atom are not equally spaced. The higher energy levels are closer together. It takes less energy to climb from one rung to another near the top of the ladder in Figure 5.2b, where the rungs are closer. Similarly, the higher the energy level occupied by an electron, the less energy it takes the electron to move from that energy level to the next higher energy level.

The Bohr model provided results in agreement with experiments using the hydrogen atom. However, the Bohr model failed to explain the energies absorbed and emitted by atoms with more than one electron.

Professional Development Note

Development of Wave Mechanics

Schrödinger's equation accounted mathematically for de Broglie's discovery of the wave-like properties of the electron. These developments led to a major break away from the Bohr model of the atom. Schrödinger extended de Broglie's work by considering the movement of a particle in an electromagnetic field, which established an area of physics known as wave mechanics.

Explain

Energy Levels in Atoms

START A CONVERSATION Prepare students for the development of atomic theory by asking questions about their understanding of what they already know about atomic theory. **Ask** What three major subatomic particles comprise an atom? *(electron, proton, and neutron)* **Ask** What electrical charges are associated with each particle? *(electron, 1–; proton, 1+; neutron, 0)* Have students describe the structure of the nuclear atom in terms of the locations of each of the subatomic particles. *(Every atom, except hydrogen, consists of a small dense nucleus composed of protons and neutrons that accounts for most of the mass of the atom. Hydrogen is an exception because it only has one proton in its nucleus.)* **Ask** Why do electrons contribute so little to the mass of an atom? *(Negatively charged electrons surround the nucleus and occupy most of its volume, but do not contribute to the actual mass of the atom.)*

USE VISUALS Call students' attention to Figure 5.2. **Ask** What are the rungs in the ladders compared to? *(the energy levels in atoms)* **Ask** How is the ladder in picture b different from the ladder in picture a? *(The rungs are not evenly spaced. They get closer together nearer to the top.)*

Explore

Teacher Demo

PURPOSE Students witness an example of quantized energy.

MATERIALS trumpet or trombone and a player

PROCEDURE Have a student blow into a trumpet or trombone. Challenge the student to produce as many different notes as he or she can without depressing any valves.

EXPECTED OUTCOMES It is not possible to play the entire scale without changing the valve positions. In the open position, no matter how much energy is put in, the instrument will only accept certain specific amounts of energy and produce certain notes. The instrument accepts quantized packages of energy.

Answers

READING SUPPORT The word quantity has the same root as quantum and means "an indefinite amount or number."

FIGURE 5.2 Less energy is required to move between the second and third rungs than between teh first and second rungs.

Explore

Teacher Demo

PURPOSE Students observe an analogy for energy transitions in atoms.

MATERIALS 1 red, 1 yellow, and 1 blue ball, step stool with 3 steps

PROCEDURE Stand on the first step of the step stool. Jump down to the floor while throwing the red ball to a student catcher. Stand on the second step and repeat the process throwing the yellow ball. Repeat jumping from the third step while throwing the blue ball. **Ask** What analogy are we trying to show you? *(The different colored balls are different amounts of energy that correspond to the energy emitted when electrons drop from excited energy levels to a lower level. Blue must be the largest amount of energy and red the smallest.)*

Explain

The Quantum Mechanical Model

MAKE A CONNECTION Draw a dartboard on the board with concentric circles of decreasing value. Draw 20 or so small solid dots and explain that the dots represent the dart holes made by two dart players. Make sure the dart holes are closer to the bull's eye than the edge. *(*The analogy will not work for professional dartboards.*)* Have students describe the distribution of the holes. *(There are more holes closer to the bull's-eye than near the edge.)*

Ask How is the distribution of holes analogous to the distribution of electrons in an atom? *(The probability diminishes with distance from the nucleus, approaching zero as distance approaches infinity.)*

Ask If the dartboard is a model for an atom, what are its major failures? *(It is a 2-dimensional model for a 3-dimensional atom; the distribution of holes may not decrease uniformly.)* Redraw the solid points of the dart holes so that the holes do decrease uniformly. **Ask** What are the probabilities for two holes on a circle at a specified distance from the center? *(The probabilities are equal.)* This rule holds true for electrons that are equidistant from the nucleus.

The Quantum Mechanical Model

What does the quantum mechanical model determine about the electrons in an atom?

The Rutherford model and the Bohr model of the atom described the path of a moving electron as you would describe the path of a large moving object. Later theoretical calculations and experimental results were inconsistent with describing electron motion this way. In 1926, the Austrian physicist Erwin Schrödinger (1887–1961) used these calculations and results to devise and solve a mathematical equation describing the behavior of the electron in a hydrogen atom. The modern description of the electrons in atoms, the **quantum mechanical model,** came from the mathematical solutions to the Schrödinger equation.

Like the Bohr model, the quantum mechanical model of the atom restricts the energy of electrons to certain values. Unlike the Bohr model, however, the quantum mechanical model does not specify an exact path the electron takes around the nucleus. **The quantum mechanical model determines the allowed energies an electron can have and how likely it is to find the electron in various locations around the nucleus of an atom.**

Probability describes how likely it is to find an electron in a particular location around the nucleus of an atom. If you placed three red marbles and one green marble into a box and then picked a marble without looking, the probability of picking the green marble would be one in four, or 25 percent. This percentage means that if you put the four marbles in a box and picked one, and repeated this many times, you would pick a green marble in 25 percent of your tries.

The quantum mechanical model description of how electrons move around the nucleus is similar to a description of how the blades of a windmill rotate. The windmill blades in Figure 5.3a have some probability of being anywhere in the blurry region they produce in the picture, but you cannot predict their exact locations at any instant. In the quantum mechanical model of the atom, the probability of finding an electron within a certain volume of space surrounding the nucleus can be represented as a fuzzy cloudlike region, as shown in Figure 5.3b. The cloud is more dense where the probability of finding the electron is high and is less dense where the probability of finding the electron is low. There is no boundary to the cloud because there is a slight chance of finding the electron at a considerable distance from the nucleus. Therefore, attempts to show probabilities as a fuzzy cloud are usually limited to the volume in which the electron is found 90 percent of the time. To visualize an electron probability cloud, imagine that you could mold a sack around the cloud so that the electron was inside the sack 90 percent of the time. The shape of the sack would then give you a picture of the shape of the cloud.

Figure 5.3 Electron Cloud
The electron cloud of an atom can be compared to a photograph of spinning windmill blades. **a.** The windmill blades are somewhere in the blurry region they produce in this picture, but the picture does not tell you their exact positions at any instant. **b.** Similarly, the electron cloud of an atom represents the locations where an electron is likely to be found, but it is not possible to know where an electron is in the cloud at any instant.

Differentiated Instruction

L1 LESS PROFICIENT READERS Have students expand Table 5.1 on page 132 to include a column with the heading *Number of orbitals* (n^2) and another headed *Number of electrons* ($2n^2$). Have students fill in the rows. Make sure students do not confuse an orbital with any predictable physical location. Concentrate primarily on *s* and *p* orbitals since these are key to understanding the behavior of representative elements.

ELL ENGLISH LANGUAGE LEARNERS Have students make a poster to show the evolution of the model of the atom. Have them start with Dalton's model and continue through all the modifications to the current quantum mechanical model. Have them include enough information to make the model clear and understandable.

L3 ADVANCED STUDENTS Have students research de Broglie's work on the wave-particle nature of matter and write a short report that explains how particles and light both produce diffraction patterns.

Atomic Orbitals

How do sublevels of principal energy levels differ?

Solutions to the Schrödinger equation give the energies, or energy levels, an electron can have. For each energy level, the Schrödinger equation also leads to a mathematical expression, called an **atomic orbital,** describing the probability of finding an electron at various locations around the nucleus. An atomic orbital is represented pictorially as a region of space in which there is a high probability of finding an electron.

The energy levels of electrons in the quantum mechanical model are labeled by principal quantum numbers (n). These numbers are assigned the values $n = 1, 2, 3, 4$, and so forth. For each principal energy level greater than 1, there are several orbitals with different shapes and at different energy levels. These energy levels within a principal energy level constitute energy sublevels.

Each energy sublevel corresponds to one or more orbitals of different shapes. The orbitals describe where an electron is likely to be found.

Different atomic orbitals are denoted by letters. As shown in Figure 5.4a, *s* orbitals are spherical, and *p* orbitals are dumbbell-shaped. The probability of finding an electron at a given distance from the nucleus in an *s* orbital does not depend on direction because of its spherical shape. The three kinds of *p* orbitals have different orientations in space. Figure 5.4b shows the shapes of *d* orbitals. Four of the five kinds of *d* orbitals have cloverleaf shapes. The shapes of *f* orbitals are more complicated than the shapes of *d* orbitals.

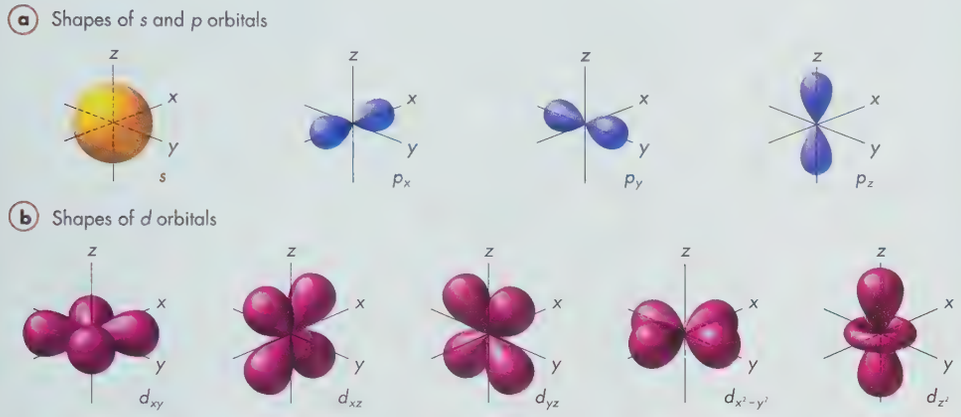

Figure 5.4 Atomic Orbitals
Solutions to the Schrödinger equation give rise to atomic orbitals. **a.** For a given principal energy level greater than 1, there is one *s* orbital and three *p* orbitals. **b.** Four of the five *d* orbitals have the same shape but different orientations in space.
Interpret Diagrams ***How are the orientations of the d_{xy} and $d_{x^2-y^2}$ orbitals similar? How are they different?***

See atomic orbitals animated online.

UbD Check for Understanding

The Essential Question **How does the quantum mechanical model describe the arrangement of electrons in atoms?**

Assess students' knowledge about the quantum mechanical model by asking them to fill in the blanks of the following prompt:

Analogy: The quantum mechanical model is like a _____ because _____.

(Sample answer: windmill, propeller blade, fan blade; it is difficult to predict what region a blade will be in, although you know that the blade is within a certain space.)

ADJUST INSTRUCTION If students are having trouble answering, have them re-read the fourth paragraph of The Quantum Mechanical Model section for review. Then ask them to complete the analogy again.

Explore

Teacher Demo

PURPOSE Students observe the shapes of *s* and *p* orbitals and their orientation in a three-dimensional coordinate system.

MATERIALS 3 metal or wooden skewers, 3 foam balls (3 or 4 inches in diameter)

PROCEDURE Push three skewers through a ball at right angles to each other and as close to the ball's center as possible. **Ask** What type of orbital does this represent? *(s)* **Ask** What is its shape? *(Students may say it is circular. Make the point that it is spherical.)* Identify the *x*-, *y*-, and *z*-axes. Push a skewer through two balls to represent a *p* orbital. Tell students that the skewer can represent any one of the three axes. **Ask** Where along the axis is the atomic nucleus? *(at the point between the two balls)*

Explain

Atomic Orbitals

INTERPRET DIAGRAMS Draw students' attention to Figure 5.4. Present the orbital concept as an outgrowth of the quantum mechanical model and describe the shapes of the *s* and *p* orbitals. Stress that the quantum mechanical model predicts the shapes of the various orbitals. The fact that experiments affirm the model's predictions is validation that the model is correct. Remind students that an orbital is only a region of mathematical probability, not a concrete item that can be seen or felt. An orbital does not have the sharp boundaries that models and diagrams seem to indicate.

Answers

FIGURE 5.4 Both lie in the *xy* plane. The lobes of the d_{xy} orbital lie between the *x* and *y* axes. Those of the $d_{x^2-y^2}$ orbital lie along the *x*- and *y*-axes.

Explain

USE VISUALS Refer students to Table 5.1. Explain that every atom has an infinite number of energy levels, but no element, when it is in its ground state, requires more than seven energy levels to describe the probability regions, *or* orbitals, where its electrons can be found. **Ask** How many sublevels are in level 5? *(5)* in level 6? *(6)* in level 7? *(7)* As a class, discuss determine the types of sublevels that are in level 5. *(5s, 1 orbital; 5p, 3 orbitals; 5d, 5 orbitals; 5f, 7 orbitals;* and *5g, 9 orbitals)* **Ask** What is the mathematical relationship between type *(s, p, d, f, g, and so on)* and number of orbitals? *(1, 3, 5, 7, 9, and so on)*. **Ask** How many orbitals relate to level 1? *(1)* level 2? *(4)* level 3? *(9)* level 4? *(16)* **Ask** Do you see a pattern? If so, describe the pattern. *(Yes; The number of orbitals is the square of the energy level,* n^2.*)* **Ask** How many orbitals would you expect to relate to level 7? *(49)*

Stress that orbitals are mathematical probability regions where electrons may be located. The equation for determining how many electrons can relate to each energy level is $2n^2$ where n represents the energy level.

CHEMISTRY & YOU The physical models of electron motion were based on describing the paths of electrons in the same way as the paths of a large moving object, and were inconsistent with theoretical calculations and experimental results.

Evaluate

Informal Assessment

Create two to three true or false questions about each model explained in the lesson. Divide students into two groups. State one of the true/false questions and allow groups time to deliberate. Tell groups to have a designated person state the answer and the reasoning for the answer. Assign one point for each correct answer and reason. The group with the most points wins. Then have students complete the 5.1 Lesson Check.

Reteach

Review the following information. Energy levels are designated with the letter n. Each energy level has as many sublevels as the number of the energy level. When $n = 2$, there are 2 sublevels. Each energy level relates to n^2 orbitals. When $n = 3$, there are 3 sublevels and 9 orbitals ($1s + 3p + 5d = 9$). Each orbital contains up to 2 electrons. The maximum number of electrons at each energy level is $2n^2$. Thus, energy level 3 has up to 18 electrons.

Table 5.1

Summary of Principal Energy Levels and Sublevels

Principal energy level	Number of sublevels	Type of sublevel	Maximum number of electrons
$n = 1$	1	1s (1 orbital)	2
$n = 2$	2	2s (1 orbital), 2p (3 orbitals)	8
$n = 3$	3	3s (1 orbital), 3p (3 orbitals), 3d (5 orbitals)	18
$n = 4$	4	4s (1 orbital), 4p (3 orbitals), 4d (5 orbitals), 4f (7 orbitals)	32

CHEMISTRY & YOU

Q: *Previous models of the atom were physical models based on the motion of large objects. Why do scientists no longer use physical models to describe the motion of electrons?*

As shown in Table 5.1, the numbers and types of atomic orbitals depend on the principal energy level. The lowest principal energy level ($n = 1$) has only one sublevel, called 1*s*. The second principal energy level ($n = 2$) has two sublevels, 2*s* and 2*p*. The 2*p* sublevel is of higher energy than the 2*s* sublevel and consists of three *p* orbitals of equal energy. Thus the second principal energy level has four orbitals (one 2*s* and three 2*p* orbitals).

The third principal energy level ($n = 3$) has three sublevels. These are called 3*s*, 3*p*, and 3*d*. The 3*d* sublevel consists of five *d* orbitals of equal energy. Thus the third principal energy level has nine orbitals (one 3*s*, three 3*p*, and five 3*d* orbitals).

The fourth principal energy level ($n = 4$) has four sublevels, called 4*s*, 4*p*, 4*d*, and 4*f*. The 4*f* sublevel consists of seven *f* orbitals of equal energy. The fourth principal energy level, then, has sixteen orbitals (one 4*s*, three 4*p*, five 4*d*, and seven 4*f* orbitals).

As shown in the table, the principal quantum number always equals the number of sublevels within that principal energy level. The number of orbitals in a principal energy level is equal to n^2. As you will learn in the next lesson, a maximum of two electrons can occupy an orbital. Therefore, the maximum number of electrons that can occupy a principal energy level is given by the formula $2n^2$.

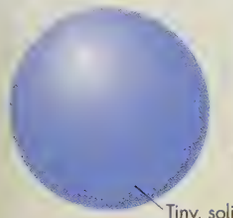
5.1 LessonCheck

1. **Review** What was the basic proposal in the Bohr model of the atom?
2. **Describe** What does the quantum mechanical model determine about electrons in atoms?
3. **Review** How do two sublevels of the same principal energy level differ from each other?
4. **Describe** How can electrons in an atom move from one energy level to another?
5. **Explain** The energies of electrons are said to be quantized. Explain what this means.
6. **Apply Concepts** How many orbitals are in the following sublevels?
   - **a.** 3*p* sublevel
   - **b.** 2*s* sublevel
   - **c.** 4*p* sublevel
   - **d.** 3*d* sublevel
   - **e.** 4*f* sublevel

BIG IDEA

ELECTRONS AND THE STRUCTURE OF ATOMS

7. How do the Bohr model and the quantum mechanical model differ in the way they describe the arrangement of electrons in atoms?



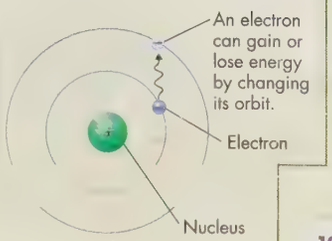
Lesson Check Answers

1. An electron is found only in specific circular paths or orbits around the nucleus.
2. It determines the allowed energy levels an electron can have and the likelihood of finding an electron in various locations around the nucleus.
3. The sublevels have different shapes.
4. by losing or gaining just the right amount of energy—a quantum
5. In an atom, the electrons can have certain fixed energy levels. To move from one energy level to another requires the emission or absorption of an exact amount of energy, or quantum. Thus the energy of the electron is said to be quantized.
6. **a.** 3 **b.** 1 **c.** 3 **d.** 5 **e.** 7
7. **BIG IDEA** The Bohr model limits electrons to specific circular paths. The quantum mechanical model expresses the probability of finding an electron in a given location within the electron cloud based on its current energy level.

CHEMISTRY & YOU: HISTORY

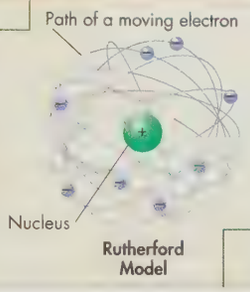
Development of Atomic Models

The atomic model has changed as scientists learned more about the atom's structure through experiments and calculations.



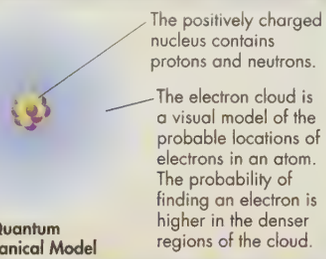
1803 John Dalton pictures atoms as tiny, indestructible particles.

1897 J.J. Thomson discovers the electron. He pictures electrons embedded in a sphere of positive electrical charge.



1904 Hantaro Nagaoka suggests that an atom has a central nucleus. Electrons move in orbits like the rings around Saturn.

1913 In Niels Bohr's model, the electron moves in a circular orbit at fixed distances from the nucleus.



1911 Ernest Rutherford finds that an atom has a small, dense, positively charged nucleus.

1923 Louis de Broglie proposes that moving particles like electrons have some properties of waves.

1926 Erwin Schrödinger develops mathematical equations to describe the motion of electrons in atoms, which leads to the quantum mechanical model.

1932 James Chadwick confirms the existence of neutrons, which have no charge. Atomic nuclei contain neutrons and positively charged protons.

1800 1805 1895 1900 1905 1910 1915 1920 1925 1930 1935

Take It Further

1. **Summarize** List a major contribution of each of these scientists to the understanding of the atom: Dalton, Thomson, Rutherford, Bohr, and Schrödinger.
2. **Describe** Have you ever needed to identify something you could not see? Explain.

Differentiated Instruction

L1 STRUGGLING STUDENTS Have students create their own model of an atom based on any of the scientists discussed in the text. The model need not be elaborate but should include labeling of the various parts and a brief description of the model.

LPR LESS PROFICIENT READERS Have students recreate the timeline shown using a poster board. Tell students to add information and diagrams that are helpful in their understanding of the development of the atomic model.

L3 ADVANCED STUDENTS Have students research early literary works of science fiction and their authors. Tell students to write their findings on note cards; each note card should state the title of the work, the author, the date of publication, and the basis of the scientific concepts that provided the foundation of the story.

CHEMISTRY & YOU Have students examine the timeline. Point out that it took over 90 years from the time that Dalton first proposed his atomic theory for the discovery of the electron to occur. As with many other important scientific discoveries, the development of a critical piece of technology led to major revisions of a long-standing theory as one new discovery led quickly to another. For example, the development of the microscope led to the discovery of the cell. The development of x-ray crystallography was necessary before the structure of DNA could be determined. In the case of the atomic model, the critical technological advance was the development of the cathode-ray tube. **Ask** Why was the development of the cathode-ray tube a turning point in the development of the modern atomic model?

Extend

Connect to LANGUAGE ARTS

Explain that some of the greatest works of literature written in this time period, such as *Frankenstein* and *Dr. Jekyl and Mr. Hyde,* were inspired by scientific discoveries of the day. Literature sometimes influences the field of science as well, as in the case of the naming of the subatomic particle known as a *quark*. Have students research the identification of the quark as a subatomic particle and write a brief paragraph about its discovery.

Answers

1. *Sample Answer:* Dalton recognized that atoms of the same element are identical. Thomson discovered the electron. Rutherford discovered that an electron has a negative charge. Bohr proposed that electrons orbited the nucleus in circular paths. Schrödinger devised and solved a mathematical equation that described the behavior of an electron in a hydrogen atom.
2. Answers will vary.

LESSON 5.2

Key Objectives

5.2.1 LIST the three rules for writing the electron configurations of elements.

Additional Resources

Reading and Study Workbook, Lesson 5.2

Available Online or on Digital Media:

- Teaching Resources, Lesson 5.2 Review

PearsonChem.com

Engage

CHEMISTRY & YOU Have students study the photograph and read the text that opens the lesson. **Ask** What role do energy and stability play in the way that electrons are configured in an atom? *(In the most stable atoms, electrons occupy the lowest possible energy orbitals.)*

Build Background

As a class, discuss processes familiar to students that follow a set of rules or guidelines. Discuss whether these rules always have to be followed, or if there are exceptions to the rules. *(Guide discussion toward rules for driving, security line at the airport, school rules, grammar rules, etc.)*

Foundations for Reading

BUILD VOCABULARY Explain that a configuration is an arrangement of parts. An electron configuration is the arrangement of electrons in orbitals around the nucleus of an atom.

IN ACADEMIC STANDARDS for SCIENCE

C.2.1 Describe how models of atomic structure changed over time based on available experimental evidence and understand the current model of atomic structure.

C.2.2 Describe how the subatomic particles (protons, neutrons, and electrons) contribute to the structure of an atom and recognize that the particles within the nucleus are held together against the electrical repulsion of the protons.

5.2 Electron Arrangement in Atoms

C.2.1 Modern atomic theory: historic development; C.2.2 Subatomic particles and atomic structure

CHEMISTRY & YOU

Q: *What makes the electron configuration of an atom stable?* Unstable arrangements, such as the yoga position shown here, tend to become more stable by losing energy. If the yogi were to fall, she would have less energy, but her position would be more stable. Energy and stability play an important role in determining how electrons are configured in an atom.

Key Question

What are the three rules for writing the electron configurations of elements?

Vocabulary

- electron configuration
- aufbau principle
- Pauli exclusion principle
- spin
- Hund's rule

Electron Configurations

What are the three rules for writing the electron configurations of elements?

In an atom, electrons and the nucleus interact to make the most stable arrangement possible. The ways in which electrons are arranged in various orbitals around the nuclei of atoms are called **electron configurations.** **Three rules—the aufbau principle, the Pauli exclusion principle, and Hund's rule—tell you how to find the electron configurations of atoms.** The three rules are as follows.

Aufbau Principle According to the **aufbau principle,** electrons occupy the orbitals of lowest energy first. The orbitals for any sublevel of a principal energy level are always of equal energy. Within a principal energy level, the *s* sublevel is always the lowest-energy sublevel. However, the range of energy levels within a principal energy level can overlap the energy levels of another principal level. Look at the aufbau diagram in Figure 5.5. Each box represents an atomic orbital. Notice that the filling of atomic orbitals does not follow a simple pattern beyond the second energy level. For example, the 4*s* orbital is lower in energy than a 3*d* orbital.

Pauli Exclusion Principle According to the **Pauli exclusion principle,** an atomic orbital may describe at most two electrons. For example, either one or two electrons can occupy an *s* orbital or a *p* orbital. To occupy the same orbital, two electrons must have opposite spins; that is, the electron spins must be paired. **Spin** is a quantum mechanical property of electrons and may be thought of as clockwise or counterclockwise. A vertical arrow indicates an electron and its direction of spin (↑ or ↓). An orbital containing paired electrons is written as ↑↓.

Hund's Rule According to **Hund's rule,** electrons occupy orbitals of the same energy in a way that makes the number of electrons with the same spin direction as large as possible. For example, three electrons would occupy three orbitals of equal energy as follows: ↑ ↑ ↑. Electrons then occupy each orbital so that their spins are paired with the first electron in the orbital.

Focus on ELL

1 CONTENT AND LANGUAGE Write the vocabulary terms on the board. Divide the class into groups and ask them to find the paragraph or section of the lesson where the definitions to each term can be found. They should notice that the vocabulary is highlighted in the text.

2 FRONTLOAD THE LESSON Point out that this lesson is about the arrangement of electrons in an atom and the rules that determine where each electron can be found. Have students brainstorm other types of arrangements they have encountered that are governed by rules.

3 COMPREHENSIBLE INPUT Have students create a two-column chart that allows them to copy the three rules for writing the electron configuration of elements in the first column and draw an example or two that they can label in the second column. A third column can be added for a native language explanation of each rule if desired.

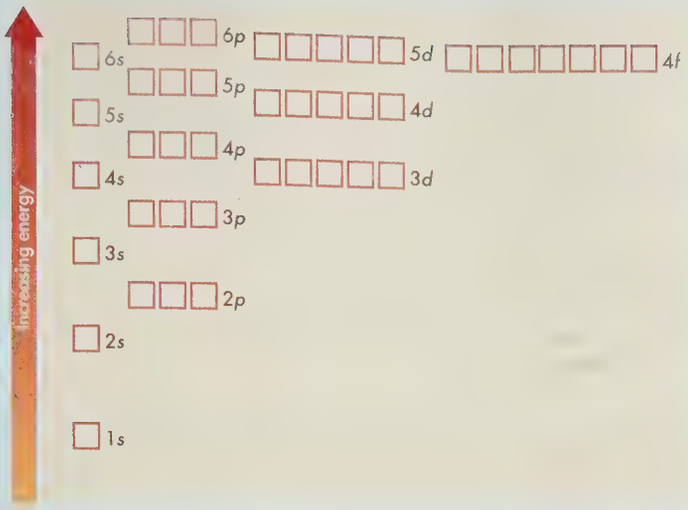

Figure 5.5 Aufbau Diagram This aufbau diagram shows the relative energy levels of the various atomic orbitals. Orbitals of greater energy are higher on the diagram. **Interpret Tables** *Which is of higher energy, a 4d orbital or a 5s orbital?*

Look at the orbital filling diagrams of the atoms listed in Table 5.2. An oxygen atom contains eight electrons. The orbital of lowest energy, 1*s*, has one electron, then a second electron of opposite spin. The next orbital to fill is 2*s*. It also has one electron, then a second electron of opposite spin. One electron then occupies each of the three 2*p* orbitals of equal energy. The remaining electron now pairs with an electron occupying one of the 2*p* orbitals. The other two 2*p* orbitals remain only half filled, with one electron each.

Table 5.2

Electron Configurations of Selected Elements

Element	1*s*	2*s*	$2p_x$	$2p_y$	$2p_z$	3*s*	Electron configuration
H	↑						$1s^1$
He	↑↓						$1s^2$
Li	↑↓	↑					$1s^2 2s^1$
C	↑↓	↑↓	↑	↑			$1s^2 2s^2 2p^2$
N	↑↓	↑↓	↑	↑	↑		$1s^2 2s^2 2p^3$
O	↑↓	↑↓	↑↓	↑	↑		$1s^2 2s^2 2p^4$
F	↑↓	↑↓	↑↓	↑↓	↑		$1s^2 2s^2 2p^5$
Ne	↑↓	↑↓	↑↓	↑↓	↑↓		$1s^2 2s^2 2p^6$
Na	↑↓	↑↓	↑↓	↑↓	↑↓	↑	$1s^2 2s^2 2p^6 3s^1$

Differentiated Instruction

LPR LESS PROFICIENT READERS Have students use a diagonal rule diagram of the aufbau principle to help them become familiar with the order in which sublevels fill when writing electron configurations.

L1 STRUGGLING STUDENTS Encourage students to draw the aufbau diagram (Figure 5.5) on a 5 x 7 card and keep it handy when writing electron configurations. Also encourage them to make flash cards, each with the name and atomic number of an element on one side and its electron configuration on the other side. Have elbow partners use the flash cards and quiz each other.

L3 ADVANCED STUDENTS Direct students to a college text and ask them to name and explain the four quantum numbers. *(The principle quantum number, n, is the energy level of the orbital; the azimuthal quantum number, l, defines the shape of the orbital; the magnetic quantum number, m, describes the orientation of the orbital in space; and the spin quantum number, m_s, denotes the direction of electron spin, + or –.)*

READING STRATEGY Encourage students to apply SQ3R as they read this section. Model how to employ it for the first two pages.

Explain

Electron Configurations

INTERPRET DIAGRAMS Direct students' attention to Figure 5.5. **Ask** Do all the orbitals at energy level $n = 4$ have the same energy? *(No, 4p orbitals have higher energy than 4s, and 4d have higher energy than 4p.)* **Ask** Which has higher energy, 4*s* or 3*d*? *(3d)*

START A CONVERSATION Develop the electron configurations for several of the simpler elements. Introduce each rule governing the process as needed. Begin with hydrogen. Use the aufbau diagram to explain that electrons enter orbitals of lowest energy first. Show how the orbital notation *($1s^1$)* describes the energy level, the orbital, and the number of electrons. Repeat the process for helium. Then continue with lithium, beryllium, and boron. Apply the Pauli exclusion principle to explain why additional orbitals must be used. When you reach carbon, explain and apply Hund's rule. Complete the configurations for the second period elements.

Explore

Class Activity

PURPOSE Students gain practice in determining the correct order for filling orbitals.

PROCEDURE Have students work with a partner to develop the electron configurations for the third period elements. When the exercise is complete, ask students to compare the configurations of second and third period elements in preparation for future discussions of the periodic table.

Answers

FIGURE 5.5 4*d*

Explain

Electron Configurations

MAKE A CONNECTION Students may ask how two negative electrons can occupy the same orbital, or why an orbital never contains more than two electrons. The answer lies in the quantum property known as spin. A spinning electron acts as a tiny magnet, with a north pole at one end and a south pole at the other. If electrons with opposite spins enter one orbital, the attraction between their opposite magnetic poles counteracts some of the electrical repulsive force. If a third electron tries to enter the orbital, its spin will always be the same as one of the existing electrons, and it will be repelled.

CHEMISTRY & YOU Electrons fill the orbitals with the lowest energy first (the aufbau principle). The 2*p* sublevel of oxygen has less energy than the 3*s* sublevel.

Sample Practice Problem

What are the electron configurations for atoms of the following elements? How many unpaired electrons does each atom have?

a. neon *($1s^2 2s^2 2p^6$; no unpaired electrons)*

b. phosphorus *($1s^2 2s^2 2p^6 3s^2 3p^3$; three unpaired electrons)*

CHEMISTRY & YOU

Q: *Explain why the correct electron configuration of oxygen is $1s^2 2s^2 2p^4$ and not $1s^2 2s^2 2p^3 3s^1$.*

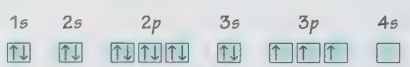
A convenient shorthand method for showing the electron configuration of an atom involves writing the energy level and the symbol for every sublevel occupied by an electron. You indicate the number of electrons occupying each sublevel with a superscript. For hydrogen, with one electron in a 1*s* orbital, the electron configuration is written $1s^1$. For helium, with two electrons in a 1*s* orbital, the configuration is $1s^2$. For oxygen, with two electrons in a 1*s* orbital, two electrons in a 2*s* orbital, and four electrons in 2*p* orbitals, the electron configuration is $1s^2 2s^2 2p^4$. Note that the sum of the superscripts equals the number of electrons in the atom.

In this book, when electron configurations are written, the sublevels within the same principal energy level are generally written together. These configurations are not always in the same order as shown on the aufbau diagram. For example, the electron configuration of bromine is written as $1s^2 2s^2 2p^6 3s^2 3p^6 3d^{10} 4s^2 4p^5$. The 3*d* sublevel is written before the 4*s* sublevel, even though the 4*s* sublevel has lower energy.

SampleProblem 5.1

Writing Electron Configurations

The atomic number of phosphorus is 15. Write the electron configuration of a phosphorus atom.



1 Analyze **Identify the relevant concepts.** Phosphorus has 15 electrons. There is a maximum of two electrons per orbital. Electrons do not pair up within an energy sublevel (orbitals of equal energy) until each orbital already has one electron.

When writing electron configurations, the sublevels within the same principal energy level are written together.

2 Solve **Apply the concepts to this problem.**

Use the aufbau diagram in Figure 5.5 to place electrons in the orbital with the lowest energy (1*s*) first. Continue placing electrons in each orbital with the next higher energy level.

Write the electron configuration.

The electron configuration of phosphorus is $1s^2 2s^2 2p^6 3s^2 3p^3$. The superscripts add up to the number of electrons.

8. Write the electron configuration for each atom.
- **a.** carbon
- **b.** argon
- **c.** nickel

9. Write the electron configuration for each atom. How many unpaired electrons does each atom have?
- **a.** boron
- **b.** silicon
- **c.** sulfur

UbD Check for Understanding

BIGIDEA **ELECTRONS AND THE STRUCTURE OF ATOMS** Give each student an index card. Assess students' knowledge of writing electron configurations of elements by reading out loud the description of each of the three rules. Students should write the name of the rule on the card in the order in which they were stated. *(the aufbau principle, the Pauli exclusion principle, and Hund's rule)*

ADJUST INSTRUCTION If students are having difficulty answering the question, have them re-read the previous page then repeat the exercise.

Exceptional Electron Configurations Copper, which is shown in Figure 5.6, has an electron configuration that is an exception to the aufbau principle. You can obtain correct electron configurations for the elements up to vanadium (atomic number 23) by following the aufbau diagram for orbital filling. If you were to continue in that fashion, however, you would assign chromium and copper the following incorrect configurations.

$$\text{Cr } 1s^2\,2s^2\,2p^6\,3s^2\,3p^6\,3d^4\,4s^2$$
$$\text{Cu } 1s^2\,2s^2\,2p^6\,3s^2\,3p^6\,3d^9\,4s^2$$

The correct electron configurations are as follows:

$$\text{Cr } 1s^2\,2s^2\,2p^6\,3s^2\,3p^6\,3d^5\,4s^1$$
$$\text{Cu } 1s^2\,2s^2\,2p^6\,3s^2\,3p^6\,3d^{10}\,4s^1$$

These arrangements give chromium a half-filled *d* sublevel and copper a filled *d* sublevel. Filled energy sublevels are more stable than partially filled sublevels. Some actual electron configurations differ from those assigned using the aufbau principle because although half-filled sublevels are not as stable as filled sublevels, they are more stable than other configurations. This tendency overcomes the small difference between the energies of the 3*d* and 4*s* sublevels in copper and chromium.

At higher principal quantum numbers, energy differences between some sublevels (such as 5*f* and 6*d*, for example) are even smaller than in the chromium and copper examples. As a result, there are other exceptions to the aufbau principle. Although it is worth knowing that exceptions to the aufbau principle occur, it is more important to understand the general rules for determining electron configurations in the many cases in which the aufbau principle applies.

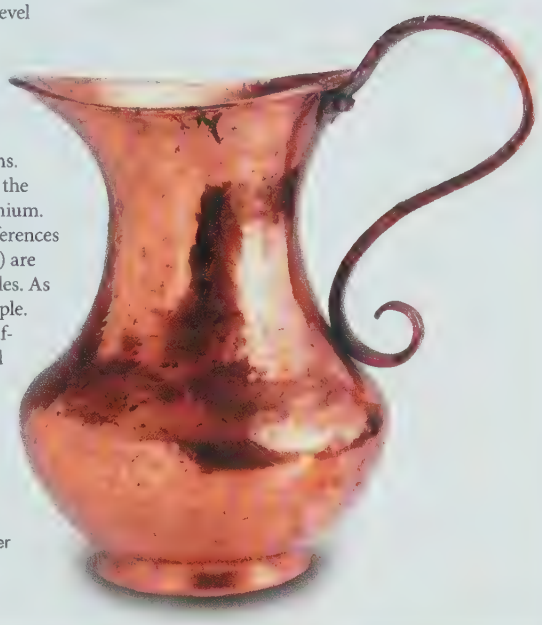


Figure 5.6 Copper
Copper is a shiny metal that can be molded into different shapes. The electron configuration of copper does not follow the aufbau principle.

5.2 LessonCheck

10. **List** What are the three rules for writing the electron configurations of elements?

11. **Sequence** Use Figure 5.5 to arrange the following sublevels in order of decreasing energy: 2*p*, 4*s*, 3*s*, 3*d*, and 3*p*.

12. **Explain** Why do the actual electron configurations for some elements differ from those assigned using the aufbau principle?

13. **Infer** Why does one electron in a potassium atom go into the fourth energy level instead of squeezing into the third energy level along with the eight already there?

14. **Apply Concepts** The atomic number of arsenic is 33. What is the electron configuration of an arsenic atom?

Lesson Check Answers

10. aufbau principle, Pauli exclusion principle, Hund's rule

11. 3*d*, 4*s*, 3*p*, 3*s*, 2*p*

12. Half-filled sublevels and filled sublevels are more stable than other configurations.

13. The 3*s* and 3*p* orbitals are already filled, so the last electron must go to the next higher energy orbital, which is 4*s*.

14. $1s^2 2s^2 2p^6 3s^2 3p^6 3d^{10} 4s^2 4p^5$

Explain

Exceptional Electron Configurations

SUMMARIZE Have students write a summary statement about why there are exceptions to the filling rules among the transition elements. *(Exceptions can be explained by the atom's tendency to keep its energy as low as possible. These exceptions help explain the unexpected chemical behavior of transition elements.)*

Extend

Connect to PHYSICS

The Pauli exclusion principle applies to all four quantum numbers of an electron. Therefore, no two electrons can have exactly the same set of quantum numbers. Refer students to the Internet or a college text to find a table summarizing the quantum numbers. Have students demonstrate the application of the Pauli exclusion principle on all quantum numbers by writing out the possible combinations of quantum numbers for a first or second period element.

Evaluate

Informal Assessment

Make a set of small cards, each with the symbol and atomic number of an element. Choose elements from throughout the periodic table. Have students choose a card and write the electron configuration for the element. Then have students complete the 5.2 Lesson Check.

Reteach

Review the three rules for writing electron configurations. Then demonstrate each rule in action by writing the electron configuration for a third period (non-transition) element.

Answers

8. **a.** $1s^2 2s^2 2p^2$
b. $1s^2 2s^2 2p^6 3s^2 3p^6$
c. $1s^2 2s^2 2p^6 3s^2 3p^6 3d^8 4s^2$

9. **a.** $1s^2 2s^2 2p^1$; one unpaired electron
b. $1s^2 2s^2 2p^6 3s^2 3p^2$; two unpaired electrons
c. $1s^2 2s^2 2p^6 3s^2 3p^4$; two unpaired electrons

LESSON 5.3

Key Objectives

- **5.3.1 EXPLAIN** what causes atomic emission spectra.
- **5.3.2 DISTINGUISH** between quantum mechanics and classical mechanics.
- **5.3.3 EXPLAIN** how the frequencies of emitted light are related to changes in electron energies.
- **5.3.4 DISTINGUISH** between quantum mechanics and classical mechanics.

- spectrum
- atomic emission spectrum
- Planck's constant
- photoelectric effect • photon
- ground state
- Heisenberg uncertainty principle

Light and Atomic Emission Spectra

What causes atomic emission spectra?

The previous sections in this chapter introduced you to some ideas about how electrons in atoms are arranged in orbitals, each with a particular energy level. You also learned how to write electron configurations for atoms. You will now get a closer look into what led to the development of Schrödinger's equation and the quantum mechanical model of the atom.

The Nature of Light Rather curiously, the quantum mechanical model grew out of the study of light. Isaac Newton (1642–1727) tried to explain what was known about the behavior of light by assuming that light consists of particles. By the year 1900, however, there was enough experimental evidence to convince scientists that light consists of waves. Figure 5.7 illustrates some of the properties of waves. As shown, each complete wave cycle starts at zero on the *y*-axis, increases to its highest value, passes through zero to reach its lowest value, and returns to zero again. The **amplitude** of a wave is the wave's height from zero to the crest, as shown in Figure 5.7. The **wavelength,** represented by λ (the Greek letter lambda), is the distance between the crests. The **frequency,** represented by ν (the Greek letter nu), is the number of wave cycles to pass a given point per unit of time. The units of frequency are usually cycles per second. The SI unit of cycles per second is called the **hertz** (Hz). A hertz can also be expressed as a reciprocal second (s^{-1}).

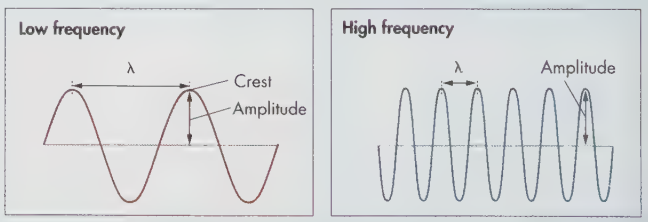

Figure 5.7 Light Waves The frequency (ν) and wavelength (λ) of light waves are inversely related. As the wavelength decreases, the frequency increases.

Focus on ELL

1 CONTENT AND LANGUAGE Write the content vocabulary that appears in the lesson, such as *amplitude, wavelength, frequency,* and *hertz* on the board. Pronounce each word and ask students to repeat. Clarify the part of speech and discuss any cognates.

2 FRONTLOAD THE LESSON Ask students for examples of where they have seen a neon sign in or around town. Have students discuss how they think the signs produce different colored lights. Direct them to the information in the opening *Chemistry & You* text and ask them to predict how an electric current might affect the atoms in these gases.

3 COMPREHENSIBLE INPUT Provide students with a step-by-step explanation of Sample Problem 5.2. Work out another example similar to Sample Problem 5.2 and have students follow the same procedure. Speak clearly and slowly and use block arrows to step out the process.

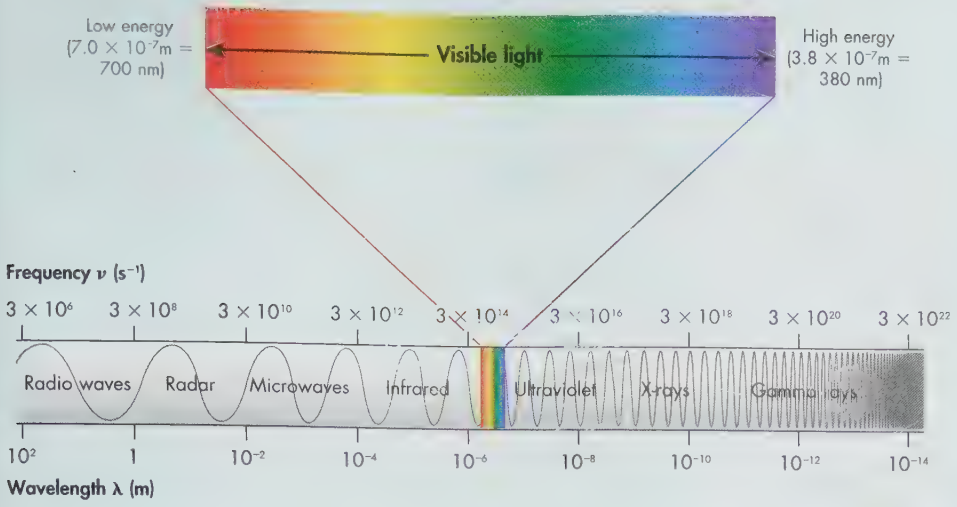

Figure 5.8 Electromagnetic Spectrum
The electromagnetic spectrum consists of radiation over a broad range of wavelengths. The visible light portion is very small. It is in the 10^{-7} m wavelength range and 10^{15} Hz (s^{-1}) frequency range.
Interpret Diagrams ***What types of nonvisible radiation have wavelengths close to those of red light? To those of blue light?***

Learn about the electromagnetic spectrum online.

The product of frequency and wavelength equals a constant (c), the speed of light.

$$c = \lambda\nu$$

The wavelength and frequency of light are inversely proportional to each other. As the wavelength of light increases, the frequency decreases.

According to the wave model, light consists of electromagnetic waves. **Electromagnetic radiation** includes radio waves, microwaves, infrared waves, visible light, ultraviolet waves, X-rays, and gamma rays. All electromagnetic waves travel in a vacuum at a speed of 2.998×10^8 m/s.

The sun and incandescent light bulbs emit white light, which consists of light with a continuous range of wavelengths and frequencies. As you can see from Figure 5.8, the wavelength and frequency of each color of light are characteristic of that color. When sunlight passes through a prism, the different wavelengths separate into a **spectrum** of colors. A rainbow is an example of this phenomenon. Each tiny droplet of water acts as a prism to produce a spectrum. Each color blends into the next in the order red, orange, yellow, green, blue, and violet. As can be seen in Figure 5.8, red light has the longest wavelength and the lowest frequency in the visible spectrum.

Professional Development Note — Light as a Particle

In 1666, Sir Isaac Newton (1642–1727) carried out important experiments with light that led to the proposal that light consists of tiny particles called corpuscles. Twelve years later, a Dutch scientist, Christian Huygens, suggested a wave theory to explain the properties of light. For more than 200 years, scientists argued about these seemingly contradictory theories. By the year 1900, most scientists had finally accepted that light could be described as a wave. Paradoxically, they soon had to accept that light could, at the same time, be described as a particle.

Foundations for Reading

BUILD VOCABULARY The word *emission* is from the Latin *emittere* meaning "to send out" The word *spectrum* is Latin for "appearance." Explain that an atomic emission spectrum allows the light sent out from an atom to be seen. **Ask** What is an emissary? *(a person sent out to represent another person)*

Explain

Light and Atomic Emission Spectra

USE VISUALS Direct students' attention to Figure 5.7. Tell students to assume that both waves are traveling at the same speed. **Ask** Which wave would have more complete wave cycles passing a point in a given time interval? *(The wave on the right.)* **Ask** Which wave has the higher frequency? *(The wave on the right.)*

INTERPRET DIAGRAMS Direct students' attention to Figure 5.8. **Ask** What are some types of radiation that are not visible? *(infrared, ultraviolet, X-rays, gamma rays)* **Ask** Are any of these invisible rays more energetic than visible light, and if so, what evidence do you have? *(UV causes suntan or sunburns, X-rays penetrate flesh, and gamma rays can penetrate bones.)* **Ask** What do all the rays in the electromagnetic spectrum have in common? *(All travel at the speed of light.)*

Explore

Student Activity

PURPOSE Students discover information about objects without seeing them.

MATERIALS several sealed boxes containing different common items such as rubber bands, golf, tennis, or table-tennis balls, cans of different sizes, and different shapes cut from blocks of wood or foam

PROCEDURE Pass the boxes around the room and record student observations and guesses about what is inside each "black box." Encourage students to move the boxes and listen to what happens. Point out that they are adding kinetic energy and observing how the hidden object responds. Point out that this method is analogous to the way scientists add energy to atoms and observe how they respond.

EXPECTED OUTCOME If the items are carefully selected, students will be surprised at how much they can determine without opening the boxes. This activity could also be done as a group activity with groups reporting what they find.

Answers

FIGURE 5.8 infrared, ultraviolet

Explain

Atomic Emission Spectra

USE VISUALS Direct students' attention to Figure 5.9. **Ask** What is the difference between the spectrum of light from an ordinary light bulb and the spectrum from a helium lamp? *(The light bulb spectrum shows a continuous display of all the colors of visible light. The helium lamp shows discrete bands of only certain frequencies of light.)* Explain that the frequencies correspond to transitions of electrons in the helium atom.

Now direct students' attention to Figure 5.10 and tell them that high voltage is required to measure the emission spectrum of a diatomic element, such as nitrogen, because the molecules must first be dissociated into atoms. The separated atoms release the absorbed energy in discrete packets with definite frequencies. Each different frequency is observed as a line in the sodium or mercury vapor emission spectrum.

Scientists who were trying to understand the inner architecture of atoms recognized a relationship between the emission spectrum of an atom and its atomic structure.

Ask Why is hydrogen a good model for studying the correlation between emission spectrum and atomic structure? *(Hydrogen, with only one electron, has the simplest electron configuration and thus the simplest emission spectrum.)*

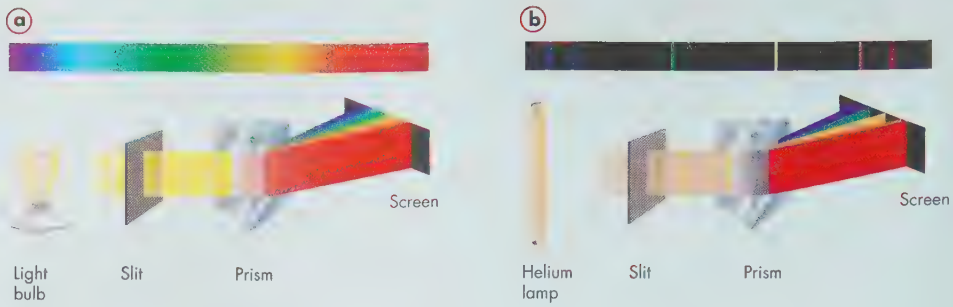

Figure 5.9 Comparing Spectra
A prism separates light into the colors it contains. **a.** White light produces a rainbow of colors. **b.** Light from a helium lamp produces discrete lines.
Identify ***Which color of the rainbow has the highest frequency?***

Atomic Emission Spectra When an electric current is passed through a gaseous element, or through the vapor of a liquid or solid element, the electrons of the atoms of the gas or vapor are energized. This energy causes them to emit light. **When atoms absorb energy, their electrons move to higher energy levels. These electrons lose energy by emitting light when they return to lower energy levels.** The energy absorbed by an electron for it to move from its current energy level to a higher energy level is identical to the energy of the light emitted by the electron as it drops back to its original energy level. Figure 5.9a shows the visible spectrum of white light. Notice that all the wavelengths of visible light are blurred together as in a rainbow. However, when the light emitted by the energized electrons of a gaseous element is passed through a prism, as shown in Figure 5.9b, the spectrum consists of a limited number of narrow lines of light. The wavelengths of these spectral lines are characteristic of the element, and they make up the **atomic emission spectrum** of the element.

Each spectral line in an atomic emission spectrum of an element corresponds to exactly one wavelength of light emitted by the electrons of that element. Figure 5.9b shows the visible portion of the atomic emission spectrum of helium.

The atomic emission spectrum of each element is like a person's fingerprint. Just as no two people have the same fingerprints, no two elements have the same atomic emission spectrum. In the same way that fingerprints identify people, atomic emission spectra are useful for identifying elements. Figure 5.10 shows the characteristic colors emitted by sodium and by mercury. Much of the knowledge about the composition of the universe comes from studying the atomic emission spectra of the stars, which are hot glowing bodies of gases.

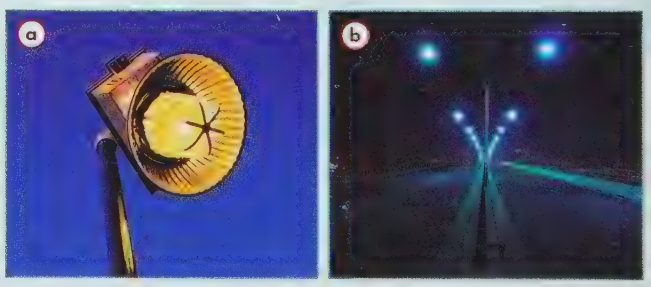

Figure 5.10
Atomic Emission Spectra
No two elements have the same atomic emission spectrum. **a.** Sodium vapor lamps produce a yellow glow. **b.** Mercury vapor lamps produce a blue glow.

Differentiated Instruction

LPR LESS PROFICIENT READERS Create a bulleted list of the important information in the text following the Atomic Emission Spectra paragraph.

L1 SPECIAL NEEDS STUDENTS When introducing the formulas and units in this section, be sure to review mathematical operations for multiplication and division using scientific notation. Also be sure to show that $1/10 = 0.10 = 10^{-1}$. This will help students understand the units used for frequency: cycles per second = cycles/s = s^{-1}, or hertz (Hz).

L3 ADVANCED STUDENTS Have students design a system for refracting light and projecting a rainbow on a wall or screen. Depending on their setup, they may need a prism and a bright light source.

Sample Problem 5.2

Calculating the Wavelength of Light

Calculate the wavelength of the yellow light emitted by a sodium lamp if the frequency of the radiation is 5.09×10^{14} Hz (5.09×10^{14}/s).

1 Analyze **List the knowns and the unknown.** Use the equation $c = \lambda\nu$ to solve for the unknown wavelength.

KNOWNS

frequency (ν) = 5.09×10^{14}/s

$c = 2.998 \times 10^{8}$ m/s

UNKNOWN

wavelength (λ) = ? m

2 Calculate **Solve for the unknown.**

Write the expression that relates the frequency and wavelength of light. $c = \lambda\nu$

Solve for λ by dividing both sides by ν: $\frac{c}{\nu} = \frac{\lambda\nu}{\nu}$

Rearrange the equation to solve for λ. $\lambda = \frac{c}{\nu}$

Substitute the known values for ν and c into the equation and solve. $\lambda = \frac{2.998 \times 10^{8}\ \text{m/s}}{5.09 \times 10^{14}/\text{s}} = 5.89 \times 10^{-7}$ m

3 Evaluate **Does the result make sense?** The magnitude of the frequency is much larger than the numerical value of the speed of light, so the answer should be much less than 1. The answer should have three significant figures.

15. What is the wavelength of radiation with a frequency of 1.50×10^{13} Hz? Does this radiation have a longer or shorter wavelength than red light?

In Problem 15, solve for wavelength.

16. What is the frequency of radiation with a wavelength of 5.00×10^{-8} m? In what region of the electromagnetic spectrum is this radiation?

In Problem 16, solve for frequency.

Foundations for Math

ALGEBRAIC EQUATIONS Tell students that solving problems in chemistry often involves manipulating literal formulas. Students need to use the inverse properties of multiplication, division, addition, and subtraction in order to solve for the unknown variable.

In **Sample Problem 5.2**, the value for ν (nu) is given and c is a constant. Point out that the equation needs to be rearranged in order to isolate λ (lambda). Show students that they can do this by dividing both sides of the equation by ν (nu).

Explore

Class Activity

PURPOSE Students gain familiarity with wavelength, frequency, and amplitude.

PROCEDURE On a sheet of paper, have students draw a horizontal line approximately 5 inches long. Then, using the line as a midpoint, ask them to draw two waves, superimposed, that have the same amplitudes but different frequencies. Have them draw another horizontal line and two waves with the same wavelength but different amplitudes.

Sample Practice Problem

What is the frequency of radiation which has a wavelength of 4.00×10^{-5} cm? *($7.49 \times 10^{12}\ s^{-1}$)* In what region of the electromagnetic spectrum is this radiation? *(infrared)*

Answers

Figure 5.9 violet

15. 2.00×10^{-5} m; longer wavelength than red light

OBJECTIVE Students use flame tests to determine the identity of the cation in an unknown solution.

SKILLS FOCUS Observe, interpret, identify

PREP TIME 30 minutes

CLASS TIME 20 minutes

MATERIALS Bunsen burner, 6 small test tubes, test tube rack, tongs, 6 cotton swabs, 0.1*M* NaCl, 0.5*M* $CaCl_2$, 0.1*M* LiCl, 0.1*M* $CuCl_2$, 0.1*M* KCl, unknown solution

ADVANCE PREP

Solution	Preparation
0.1 *M* NaCl	0.6 g NaCl in 100 mL water
0.5 *M* $CaCl_2$	5.5 g $CaCl_2$ in 100 mL water
0.1 *M* LiCl	0.5 g LiCl in 100 mL water
0.1 *M* $CuCl_2$	1.3 g $CuCl_2$ in 100 mL water
0.1 *M* KCl	0.8 g KCl in 100 mL water

SAFETY Students should wear safety goggles and a lab apron and observe all safety procedures.

EXPECTED OUTCOME

Na^+	bright yellow
Ca^{2+}	orange-red
Li^+	bright crimson red
Cu^{2+}	blue-green
K^+	light purple

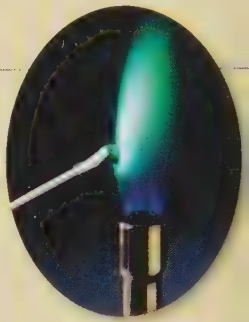
ANALYZE AND CONCLUDE

1. Answer depends on the unknown.
2. Yes; because the composition of every atom is different, the amount of energy needed for transitions between energy sublevels is different. These energy differences are reflected in the different line spectra.
3. copper (green), lithium (red), or calcium (orange-red)
4. red, lithium; yellow, sodium

FOR ENRICHMENT Mix two unknown solutions. Ask students to identify the two metal ions.

QuickLab

Purpose To determine the identity of the metal in an unknown solution based on its characteristic color in a flame



Materials

- 6 small test tubes
- sodium chloride (NaCl) solution
- calcium chloride ($CaCl_2$) solution
- lithium chloride (LiCl) solution
- copper(II) chloride ($CuCl_2$) solution
- potassium chloride (KCl) solution
- unknown solution
- 6 cotton swabs
- gas burner

Flame Tests

Procedure

1. Make a two-column data table. Label the columns Metal and Flame Color. Enter the metal's name for each solution in the first column.
2. Label each of five test tubes with the name of a solution; label the sixth tube Unknown. Add 1 mL of each solution to the appropriately labeled test tube.
3. Dip one of the cotton ends of a cotton swab into the sodium chloride solution and then hold it briefly in the burner flame. Record the color of the flame. Do not leave the swab in the flame too long or the plastic will melt.
4. Repeat Step 3 for each of the remaining solutions using a new cotton swab each time.
5. Perform a flame test with the unknown solution. Note the color of the flame.

Analyze and Conclude

1. **Identify** What is the metal in the unknown?
2. **Draw Conclusions** Each solution produces a unique color. Would you expect this result based on the modern view of the atom? Explain.
3. **Analyze Data** Some commercially available fireplace logs burn with a red and/or green flame. What elements could be responsible for these colored flames?
4. **Predict** Aerial fireworks contain gunpowder and chemicals that produce colors. What element would you include to produce crimson red? Yellow?

The Quantum Concept and Photons

How did Einstein explain the photoelectric effect?

According to the laws of classical physics, the atomic emission spectrum of an element should be continuous. Thus, classical physics does not explain the emission spectra of atoms, which consist of lines.

The Quantization of Energy Recall the iron scroll in Figure 5.1 that changed color when heated. In 1900, the German physicist Max Planck (1858–1947) was trying to describe why such a body first appears black, then red, then yellow, and then white as its temperature increases. Planck found that he could explain the color changes if he assumed that the energy of a body changes only in small discrete units, or quanta. Planck showed mathematically that the amount of radiant energy (E) of a single quantum absorbed or emitted by a body is proportional to the frequency of radiation (ν).

$$E \propto \nu \text{ or } E = h\nu$$

Focus on ELL

4 LANGUAGE PRODUCTION Have students work in groups of four to complete the lab. Make sure each group has ELLs of varied language proficiencies, so that more proficient students can help less proficient ones. Have students work according to their proficiency level.

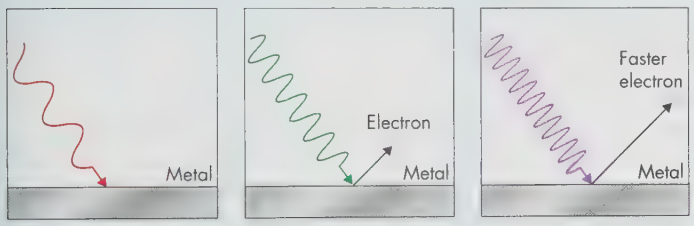
BEGINNING

LOW Model this lab and ask students to say the color that each metal produces. Ask students to discuss the color of the unknown metal.

HIGH Provide students with a chart of the solutions and then a column for them to write the color produced.

INTERMEDIATE: LOW/HIGH Have students predict which metal represents their unknown and compare the result with their prediction. Allow students to orally present their results.

ADVANCED: LOW/HIGH Ask students to complete the Analyze and Conclude questions with written responses.



The constant (h), which has a value of 6.626×10^{-34} J•s, (J is the joule, the SI unit of energy) is called **Planck's constant.** The energy of a quantum equals $h\nu$. A small energy change involves the emission or absorption of low-frequency radiation. A large energy change involves the emission or absorption of high-frequency radiation.

The Photoelectric Effect A few years after Planck presented his theory on the quantization of energy, scientists began to use it to explain many experimental observations that could not be explained by classical physics. In 1905, Albert Einstein (1879–1955), then a patent examiner in Bern, Switzerland, used Planck's quantum theory to explain the photoelectric effect, which is illustrated in Figure 5.11. In the **photoelectric effect,** electrons are ejected when light shines on a metal. Not just any frequency of light will cause the photoelectric effect. For example, red light will not cause potassium to eject electrons, no matter how intense the light. Yet a very weak yellow light shining on potassium begins the effect.

The photoelectric effect could not be explained by classical physics. Although classical physics correctly described light as a form of energy, it assumed that under weak light of any wavelength, an electron in a metal should eventually collect enough energy to be ejected. The photoelectric effect presented a serious problem for the classical wave theory of light.

To explain the photoelectric effect, Einstein proposed that light could be described as quanta of energy that behave as if they were particles. These light quanta are called **photons.** The energy of photons is quantized according to the equation $E = h\nu$. Einstein recognized that there is a threshold value of energy below which the photoelectric effect does not occur. According to $E = h\nu$, all the photons in a beam of monochromatic light (light of only one frequency) have the same energy. If the frequency, and therefore the energy, of the photons is too low, then no electrons will be ejected. It does not matter whether a single photon or a steady stream of low-energy photons strikes an electron in the metal. Only if the frequency of light is above the threshold frequency will the photoelectric effect occur.

Einstein's theory that light behaves as a stream of particles explains the photoelectric effect and many other observations. However, light also behaves as waves in other situations. Therefore, we must consider that light possesses both wavelike and particle-like properties.

No electrons are ejected because the frequency of the light is below the threshold frequency.

If the light is at or above the threshold frequency, electrons are ejected.

If the frequency is increased, the ejected electrons will travel faster.

Figure 5.11
Photoelectric Effect
Einstein explained the photoelectric effect by proposing that light behaves as particles.
Predict *What will happen if ultraviolet light shines on the metal?*

UbD Check for Understanding

The Essential Question **What happens when electrons in atoms absorb or release energy?**

Have students write a brief one-minute summary that explains what they know about the absorption and release of energy by electrons in atoms. Summaries should reference the change in energy levels of the electrons and the photoelectric effect.

ADJUST INSTRUCTION If students are having difficulty writing their summaries, briefly review how atomic emission spectra are generated. Connect this concept to the photoelectric effect.

Explain

The Quantum Concept and Photons

APPLY CONCEPTS Determine by a show of hands how familiar students are with solar-powered landscaping lights or photoelectric cells. Explain that landscaping lights use photoelectric cells to convert solar (light) energy to electrical energy. The specially treated material used to make photoelectric cells has a positive and a negative side. When light strikes this material, electrons are emitted. The electrons move toward the positive side of the material in a current. This current is stored in batteries until the lights come on at dusk.

Extend

Connect to PHYSICS

Max Planck (1858–1947) showed that energy could be absorbed or emitted by a body only in quanta whose energy is given by the equation $E = h \times \nu$, where h is a proportionality constant called Planck's constant. Planck's proposal was revolutionary. Everyday experience had led people to believe that no limitation existed for the smallness of permissible energy changes in a system. For example, appearances would lead you to believe that thermal energy may be continuously supplied to heat liquid water to any temperature between 0°C and 100°C. Actually, the water temperature increases by infinitesimally small steps that occur as individual molecules absorb quanta of energy. Have students research Max Planck and write a summary about his other scientific discoveries.

Answers

FIGURE 5.11 an electron will be ejected from the metal

Extend

Connect to PHYSICS

Explain that the word *laser* is an acronym for **light amplification by the stimulated emission of radiation.** Encourage students to find out how coherent light—light with one wavelength—is produced. *(When a photon of a particular frequency strikes an atom, the photon stimulates the atom to emit a photon of the same frequency. The original photon is unaffected. Now two photons of the same frequency can collide with other atoms and stimulate them to produce identical photons. The process goes on building up an aggregate of photons all with the same frequency.)* Have students investigate what substances are stimulated to create laser light and what wavelengths correspond to each substance. *(Sample answers: Some typical lasers are nitrogen, $\lambda = 337$ nm; helium-cadmium, $\lambda = 441.6$ nm; argon, $\lambda = 476.5$ and 488.0 nm; krypton, $\lambda = 534.5$ nm; ruby, $\lambda = 694.3$ nm; neon, $\lambda = 632,8$ nm; gallium arsenide, $\lambda = 840–930$ nm, depending on temperature; neodynium, $\lambda = 1040$ nm; carbon dioxide, $\lambda = 10,600$ nm)*

Sample Practice Problem

What is the energy of a photon of red light with a frequency of 4.30×10^{14}/s? *(2.85×10^{-22} J)*

Sample Problem 5.3

Calculating the Energy of a Photon

What is the energy of a photon of microwave radiation with a frequency of 3.20×10^{11}/s?

KNOWNS

frequency (ν) = 3.20×10^{11}/s

$h = 6.626 \times 10^{-34}$ J·s

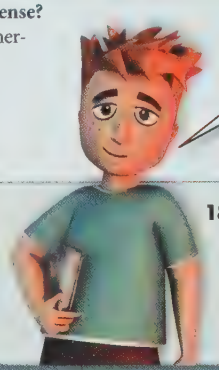
UNKNOWN

energy (E) = ? J

1 Analyze **List the knowns and the unknown.** Use the equation $E = h\nu$ to calculate the energy of the photon.

2 Calculate **Solve for the unknown.**

Write the expression that relates the energy of a photon of radiation and the frequency of the radiation.



$E = h\nu$

Substitute the known values for ν and h into the equation and solve.

$E = (6.626 \times 10^{-34}\ \text{J·s}) \times (3.20 \times 10^{11}/\text{s})$

$= 2.12 \times 10^{-22}$ J

3 Evaluate **Does the result make sense?** Individual photons have very small energies, so the answer seems reasonable.

In Problem 18, use the equation $c = \lambda\nu$ to calculate the frequency of light from the wavelength. Then, calculate the energy.

17. Calculate the energy of a quantum of radiant energy with a frequency of 5.00×10^{11}/s.

18. The threshold photoelectric effect in tungsten is produced by light of a wavelength 260 nm. Give the energy of a photon of this light in joules.

An Explanation of Atomic Spectra

How are the frequencies of light emitted by an atom related to changes of electron energies?

Atomic emission spectra were known before Bohr proposed his model of the hydrogen atom. Bohr applied quantum theory to electron energy levels in atoms to explain the atomic emission spectrum of hydrogen. Bohr's model not only explained why the atomic emission spectrum of hydrogen consists of specific frequencies of light, but it also predicted specific values of these frequencies that agreed with the experimental results.

Foundations for Math

SCIENTIFIC NOTATION Review with students that a number written in proper scientific notation form must have a coefficient greater than or equal to 1 and less than 10, a base of 10 and an exponent to indicate the number of decimal places that the decimal needs to be moved to change the number to standard notation. To find the product of numbers written in scientific notation, you multiply the coefficients, keep the base the same, and add the exponents.

In **Sample Problem 5.3**, the Associative Property of Multiplication can be used to find the product of $h \times \nu$. Begin by regrouping the terms:

$E = h\nu = (6.626 \cdot 10^{-34}\ \text{J} \cdot \text{s}) \cdot (3.20 \cdot 10^{11}/\text{s})$

$= (6.626 \times 3.20)\ (10^{-34} \times 10^{11})\ \text{J}$

Next, multiply the coefficients, add the exponents, and simplify:

$= 21.2 \times 10^{-34+11}\ \text{J} = 21.2 \times 10^{-23}\ \text{J}$

Finally, move the decimal one place to the left:

$= 2.12 \times 10^{-22}\ \text{J}$

In the Bohr model, the lone electron in the hydrogen atom can have only certain specific energies. When the electron has its lowest possible energy, the atom is in its **ground state.** In the ground state, the principal quantum number (n) is 1. Excitation of the electron by absorbing energy raises the atom to an excited state with $n = 2, 3, 4, 5$, or 6, and so forth. A quantum of energy in the form of light is emitted when the electron drops back to a lower energy level. The emission occurs in a single step, called an electronic transition. Bohr already knew that this quantum of energy E is related to the frequency ν of the emitted light by the equation $E = h\nu$. **The light emitted by an electron moving from a higher to a lower energy level has a frequency directly proportional to the energy change of the electron.** Therefore, each transition produces a line of a specific frequency in the spectrum.

Figure 5.12 shows the three groups of lines in the emission spectrum of hydrogen atoms. The lines at the ultraviolet end of the hydrogen spectrum are the Lyman series. These lines are due to the transitions of electrons from higher energy levels to the lowest energy level, $n = 1$. The lines in the visible spectrum are the Balmer series. These lines result from transitions from higher energy levels to $n = 2$. These transitions generally involve a smaller change in electron energy than transitions to $n = 1$. Transitions to $n = 3$ from higher energy levels produce the Paschen series. The energy changes of the electron are generally smaller still. The lines are in the infrared range. Spectral lines for the transitions from higher energy levels to $n = 4$ and $n = 5$ also exist. Note that the spectral lines in each group become more closely spaced at increased values of n because the energy levels become closer together. There is an upper limit to the frequency of emitted light for each set of lines because an electron with enough energy completely escapes the atom.

Bohr's model explained the atomic emission spectrum of hydrogen but not the emission spectra of atoms with more than one electron. Also, it did not help in understanding how atoms bond to form molecules. Eventually the quantum mechanical model displaced the Bohr model of the atom.

CHEMISTRY & YOU

Q: *The glass tubes in lighted signs contain helium, neon, argon, krypton, or xenon gas, or a mixture of these gases. Why do the colors of the light depend on the gases that are used?*

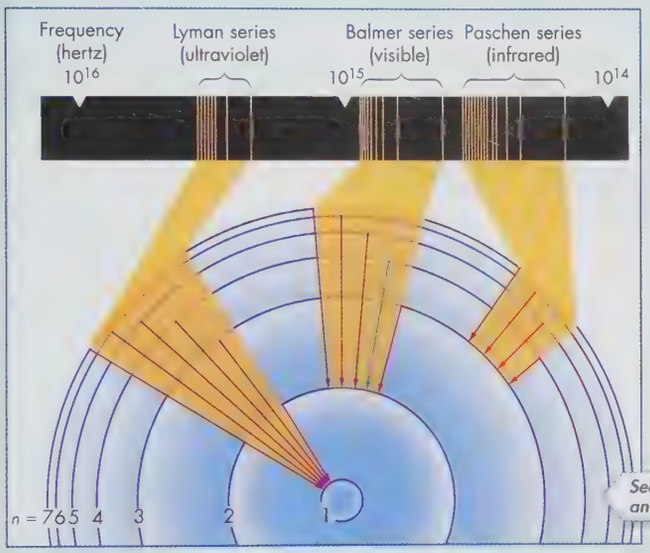


Figure 5.12 The Hydrogen Spectrum The three groups of lines in the hydrogen spectrum correspond to the transitions of electrons from higher energy levels to lower energy levels. **Interpret Diagrams** *Which of the following transitions produces the spectral line having the longest wavelength (lowest frequency): $n = 2$ to $n = 1$, $n = 3$ to $n = 2$, or $n = 4$ to $n = 3$?*

See the hydrogen spectrum animated online.

UbD Check for Understanding

How are the frequencies of light emitted by an atom related to changes of electron energies?

Assess students' understanding of how atomic spectra occur by having students rephrase the key answer in their own words. *(Sample answer: When an electron moves from a higher to a lower energy level, its frequency will be in direct proportion to its change in energy.)*

ADJUST INSTRUCTION If students are struggling to understand this concept, review the difference between direct and indirect proportionality. Then re-write Planck's equation on the board to isolate frequency. Ask students to identify what would happen to frequency if E is increased. *(frequency would increase)* **Ask** What happens to frequency if E decreases? *(frequency would decrease)* Point out that the two values are directly proportional because both increase or both decrease. If they were indirectly proportional, then an increase in one would cause a decrease in the other.

Explain

An Explanation of Atomic Spectra

CHEMISTRY & YOU Each gas emits light at a different wavelength. This wavelength determines the characteristic color of light associated with a particular gas.

USE VISUALS Direct students' attention to Figure 5.12. **Ask** Suppose an electron, in its ground state at energy level one, absorbs enough energy to jump to level two. What type of radiation will it emit when it returns to the ground state? *(UV radiation)* **Ask** If you observed a hydrogen gas discharge tube through a diffraction grating, could you see the line corresponding to this emission? *(No)* Why not? *(The human eye cannot detect radiation in the UV range.)* **Ask** Which series of lines could you detect? *(the Balmer series, which has frequencies in the visible region of the spectrum)*

Have students compare the energy of the Paschen and Balmer series. *(The Paschen series has lower energy.)* **Ask** What do you notice about the spacing of the energy levels from $n = 1$ to $n = 7$? *(The levels are not evenly spaced. The lines get closer as the distance from the nucleus increases.)*

Point out that each set of lines is a converging series that approaches the ionization energy of hydrogen.

CRITICAL THINKING Point out to students that astronomers are able to identify the composition of stars that are at the farthest reaches of the universe, even though no technology exists that allows them to take actual samples of the gases that make up these stars. Have students use what they have learned about atomic emission spectra to explain how scientists can identify these gases.

Answers

17. 2.31×10^{-22} J

18. 8.0×10^{-9}

FIGURE 5.12 $n = 4$ to $n = 3$

CHEMISTRY & YOU Call students' attention to the cut-out diagram of the LED. Explain how an LED works by first defining what a "diode" is: a small semiconductor that allows electrons to flow in only one direction across a material when a direct current is applied. Then explain that the light emitted from a diode is the result of the electrons from the atoms moving from the negative pole of the direct current to the positive pole. The light that is emitted is in the form of particles called "photons", which are small particles that have energy and momentum, but no mass.

Remind students that earlier they learned of another use of semiconductors: photoelectric cells. **Ask** How do photoelectric cells work? *(Sunlight causes the semiconductor material to emit electrons, which form a current by travelling between the negatively and positively charged sides of the semiconductor material.)* **Ask** What type of energy conversion occurs in photoelectric cells? *(light energy is converted to electrical energy)* Point out that in LEDs, the opposite conversion is taking place—electrical energy is being converted to light energy.

Extend

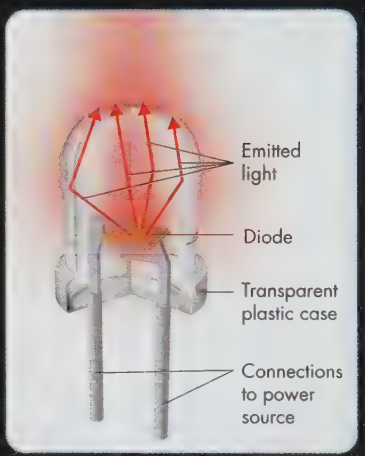
Connect to ECONOMICS

Lead students in a discussion about the efficiency of LED lighting. Discuss the respective amounts of energy needed to illuminate an LED bulb, a fluorescent bulb, and an incandescent bulb all of the same wattage output. Discuss the varying life expectancy of the three types of bulbs.

Have students prove mathematically that LED bulbs use less energy and cost less to operate than incandescent lights. Provide students with the following formulas: *Energy = power × time*, and *Cost of energy use = Energy × Cost of energy per unit*. Tell students to use $0.10 per kilowatt-hours for the cost of energy per unit, and to submit a source supporting the initial cost of the light. Have students research the amount of energy used per hour for a 60-watt incandescent bulb and an LED bulb, and calculate the cost of illuminating each bulb for 24 hours per day for one year. Compare the costs and determine which type of bulb is the most cost effective. Ask students to predict how a fluorescent light compares to the cost and efficiency of incandescent and LED lights.

CHEMISTRY & YOU: TECHNOLOGY

Light Emitting Diodes



Although they are small, you may have seen light emitting diodes, or LEDs, several times today. These tiny light bulbs may form the numbers on your digital clock, light up your watch, or illuminate the traffic light you stopped at on your way to school. You may have even watched television on a giant screen made out of LEDs.

Light from a typical incandescent bulb is generated when the filament inside the bulb is heated. Light from an LED is generated in a different way. A diode is made out of two materials with different properties. The electrons in one of the materials are at a higher energy level than the electrons in the other material. When a voltage, supplied by a battery or other power supply, is applied to the diode, electrons flow across the boundary between the two materials. The electrons at the higher energy level flow into the other material, fall to a lower energy level, and emit light.

LEDs last much longer than incandescent light bulbs because there is no filament to burn out. Also, a large amount of the energy that is used to produce light in an incandescent bulb is wasted as heat. However, LEDs produce very little heat, so they use less energy and cost less to operate than incandescent lights.

Take It Further

1. **Apply Concepts** LEDs that produce infrared light can be used to transmit information from remote controls. What range of frequencies of light would an LED used in a remote control emit?
2. **Infer** What determines the frequency and wavelength of light emitted by an LED?
3. **Calculate** An LED produces orange light with a wavelength of 605 nm. What is the frequency of this light? What is the energy change of the electrons in the LED as they emit the light?

146 Chapter 5 • Chemistry & You

21st Century Learning To be successful in the 21st century, students need skills and learning experiences that extend beyond subject matter mastery. The following project helps students build the following 21st Century Skills: *Financial, Economic, Business, and Entrepreneurial Literacy*; *Creativity and Innovation*; *Communication and Collaboration*; *Information, Media, and Technology Literacy*; *Initiative and Self-Direction*; and *Productivity and Accountability*.

Pose the following challenge to the students: *Conduct a cost benefit analysis of upgrading the lighting in your home from incandescent to LED. Submit your report in electronic form, including any spreadsheets and graphs that were generated as a result of your analysis.*

You may need to guide the students in the following ways:

- A cost benefit analysis quantifies the benefits, or positive aspects, of a project and compares this quantity to the total costs, or negative aspects, of the project.
- Electrical customers are billed in cents per KWH (kilowatt-hour). A rate schedule is available from the local electrical utility.

Quantum Mechanics

How does quantum mechanics differ from classical mechanics?

In 1924, Louis de Broglie (1892–1987), a French graduate student, asked an important question: Given that light behaves as waves and particles, can particles of matter behave as waves? De Broglie referred to the wavelike behavior of particles as matter waves. His reasoning led him to a mathematical expression for the wavelength of a moving particle.

The Wavelike Nature of Matter The proposal that matter moves in a wavelike way would not have been accepted unless experiments confirmed its validity. Only three years later, experiments by Clinton Davisson and Lester Germer at Bell Labs in New Jersey did just that. The two scientists had been studying the bombardment of metals with beams of electrons. They noticed that the electrons reflected from the metal surface produced curious patterns. The patterns were like those obtained when X-rays (which are electromagnetic waves) reflect from metal surfaces. The electrons, which were believed to be particles, were reflected as if they were waves! De Broglie was awarded the Nobel prize for his work on the wave nature of matter. Davisson also received the Nobel prize for his experiments demonstrating the wave nature of electrons.

Today, the wavelike properties of beams of electrons are useful in viewing objects that cannot be viewed with an optical microscope. The electrons in an electron microscope have much smaller wavelengths than visible light. These smaller wavelengths allow a much clearer enlarged image of a very small object, such as the pollen grain in Figure 5.13, than is possible with an ordinary microscope.

De Broglie's equation predicts that all moving objects have wavelike behavior. Why are you unable to observe the effects of this wavelike motion for ordinary objects like baseballs and trains? The answer is that the mass of the object must be very small in order for its wavelength to be large enough to observe. For example, a 50-gram golf ball traveling at 40 m/s (about 90 mi/h) has a wavelength of only 3×10^{-34} m, which is much too small to detect experimentally. On the other hand, an electron has a mass of only 9.11×10^{-28} g. If it were moving at a velocity of 40 m/s, it would have a wavelength of 2×10^{-5} m, which is comparable to infrared radiation and is readily measured.

De Broglie's prediction that matter exhibits both wave and particle properties set the stage for a new way of describing the motions of subatomic particles and atoms. The newer theory is called quantum mechanics; the older theory is called classical mechanics. **Classical mechanics adequately describes the motions of bodies much larger than atoms, while quantum mechanics describes the motions of subatomic particles and atoms as waves.**

Figure 5.13 Electron Micrograph
An electron microscope can produce sharp images of a very small object, such as this pollen grain, because of the small wavelength of a moving electron compared with that of light.

Professional Development Note

A Scientific Controversy

Albert Einstein and Niels Bohr had different views of quantum mechanics. Although Einstein accepted quantum mechanical theory as the best explanation available at the time, he was convinced the theory was incomplete. He believed in the existence of "hidden variables" which, if known, would eliminate problems such as wave-particle duality and uncertainty. Bohr, on the other hand, urged physicists to accept quantum mechanics without qualification.

Explain

Quantum Mechanics

INTERPRET DATA The wave-particle behavior of light was difficult for scientists trained in classical physics to accept. However, it became difficult to dispute because it provided an explanation for a previously mysterious phenomenon called the photoelectric effect. In the photoelectric effect, it was shown that metals eject electrons called photoelectrons when light shines on them. But not just any frequency of light will cause the photoelectric effect. Red light ($\nu = 4.3 \times 10^{14}$ s^{-1} to 4.6×10^{14} s^{-1}), for example, will not cause the ejection of photoelectrons from potassium, no matter how intense the light or for how long the light radiates the metal surface. But even a weak yellow light ($\nu = 5.1 \times 10^{14}$ s^{-1} to 5.2×10^{14} s^{-1}) shining on potassium causes the emission of photoelectrons. Thus, photons of red light do not have sufficient energy to cause the ejection of electrons, but photons of yellow light do.

ClassActivity

ATOMIC SCIENTISTS Numerous physicists contributed to modern theories of light and atoms. Dalton, Becquerel, Roentgen, Rutherford, Thomson, Millikan, Planck, Einstein, de Broglie, Heisenberg, Schrödinger, Bohr, Chadwick, Balmer, Huygens, Newton, and Foucault all made contributions in one of the most productive periods of scientific discovery.

PURPOSE Students acquire a deeper understanding and appreciation for the achievements of these scientists.

PROCEDURE Have students work in teams of two or three. Assign scientists to each group and ask students to prepare a brief oral discussion highlighting how the work of the scientists contributed to the understanding of light or the atom. Encourage students to consider the work of other scientists they encounter in their research. Contributions at the periphery can help students understand the interactive and collaborative nature of scientific research.

EXPECTED OUTCOME Class presentations allow students to share information.

Answers

TAKE IT FURTHER

1. 3×10^{14} to 3×10^{12} s^{-1}
2. The size of the energy change of the transition from a higher energy level to a lower energy level determines the frequency and wavelength of light emitted by an LED.
3. $\nu = 4.96 \times 10^{14}$ s^{-1}; $E = 3.29 \times 10^{-19}$ J

Explain

USE AN ANALOGY Tell students that, according to quantum mechanics, scientists cannot observe an object without changing the object in the process. The change produced by making an observation is the basis for the uncertainty principle. Present the following analogy: Suppose you want to find out if a car is in a long tunnel. In quantum mechanics, the only sort of experiment you could do would be to send another car into the tunnel and listen for a crash. Although it is possible to detect the presence of a car with this method, it is obvious that the car will be changed by the crash.

Misconception Alert

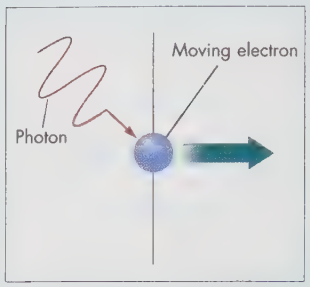
Refer students to Figure 5.14 and the supporting text. Often students think that Heisenberg's principle is a technological limitation of the time in which it was discovered. Point out that this principle is in fact based on a physical limit—the level of precision that can be achieved when measuring the momentum of a particle.

Evaluate

Informal Assessment

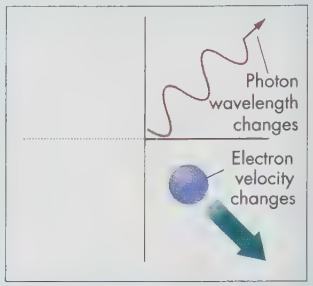
In small groups, have students draw and label wave diagrams that illustrate the relationship between wavelength and frequency. Ask students to explain the origin of the lines in the Lyman, Balmer, and Paschen series in the atomic emission spectrum of hydrogen. *(Each line arises from light emitted by an atom as electrons move from a higher energy level to a lower one. The Lyman series is in the ultraviolet region of the spectrum, the Balmer is in the visible, and the Paschen is in the infrared.)*

Reteach



Use the illustrations in this lesson as a basis for review. Starting with Figure 5.7 and continuing to Figure 5.14, question students about what is being illustrated and what is significant about it.

The Heisenberg Uncertainty Principle German physicist Werner Heisenberg examined another feature of quantum mechanics. The **Heisenberg uncertainty principle** states that it is impossible to know both the velocity and the position of a particle at the same time. This limitation is critical when dealing with small particles such as electrons, but it does not matter for ordinary-sized objects such as cars or airplanes.



Consider how you determine the location of an object. To locate a set of keys in a dark room you can use a flashlight. You see the keys when the light bounces off them and strikes your eyes. To locate an electron, you might strike it with a photon of light, as shown in Figure 5.14. However, the electron has such a small mass that striking it with a photon affects its motion in a way that cannot be predicted accurately. The very act of measuring the position of the electron changes its velocity, making its velocity uncertain.

The discovery of matter waves led the way for Schrödinger's quantum mechanical description of electrons in atoms. Schrödinger's theory leads to the concept of electron orbitals and includes the uncertainty principle.

Figure 5.14 Heisenberg Uncertainty Principle
According to the Heisenberg uncertainty principle, it is impossible to know exactly both the velocity and the position of a particle at the same time.

Before collision A photon strikes an electron during an attempt to observe the electron's position.

After collision The impact changes the electron's velocity, making it uncertain.

5.3 LessonCheck

19. Describe What is the origin of the atomic emission spectrum of an element?

20. Review What was Einstein's explanation for the photoelectric effect?

21. Explain How is the change in electron energy related to the frequency of light emitted in electronic transitions?

22. Explain How does quantum mechanics differ from classical mechanics?

23. Sequence Arrange the following in order of decreasing wavelength.
- **a.** infrared radiation from a heat lamp
- **b.** dental X-rays
- **c.** signal from a shortwave radio station

24. Calculate A hydrogen lamp emits several lines in the visible region of the spectrum. One of these lines has a wavelength of 6.56×10^{-5} cm. What is the frequency of this radiation?

25. Calculate What is the energy of a photon of blue light with a wavelength of 460 nm?

BIG IDEA
ELECTRONS AND THE STRUCTURE OF ATOMS

26. When a strontium compound is heated in a flame, red light is produced. When a barium compound is heated in a flame, yellow-green light is produced. Explain why these colors are emitted.

Lesson Check Answers

19. Electrons in atoms absorb energy as they move to higher energy levels, then lose the energy by emitting it as light as they drop back.

20. He proposed that light could be described as quanta of energy that behave as if they were particles.

21. The light emitted in an electronic transition from a higher to a lower energy level has a frequency that is directly proportional to the energy change of the electron.

22. Quantum mechanics describes the motions of atoms and subatomic particles; classical mechanics describes the motions of larger bodies.

23. *c, a, b*

24. $4.57 \times 10^{14}\ s^{-1}$

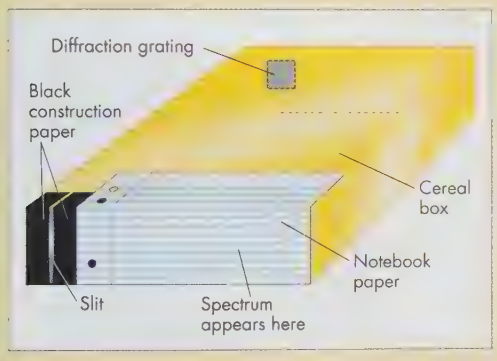
25. 4.32×10^{-19} J

26. BIG IDEA The colors, when separated by a spectroscope, are the colors of the identifying lines for strontium and barium and arise from electrons moving from higher energy levels to lower energy levels.

Small-Scale Lab

Atomic Emission Spectra

Purpose



To build a spectroscope and use it to measure the wavelengths, frequencies, and energies of atomic emission lines

Materials

- black construction paper
- tape
- cereal box
- scissors
- white notebook paper
- diffraction grating
- ruler

Procedure

Tape together two 2.0 cm × 10 cm strips of black construction paper so that they are parallel and form a narrow slit about 2 mm wide. Remove the top of a cereal box and tape the construction paper slit as shown. Cover the rest of the opening with white notebook paper. Cut a square hole (approximately 2 cm per side) and tape a diffraction grating over the hole as shown. Point the spectroscope toward a fluorescent light. Tape up any light leaks. Your lab partner should mark the exact positions of all the colored emission lines you see on the notebook paper. Measure the distances between the violet line and the other lines you have marked.

Analyze and Conclude

1. Observe List the number of distinct lines that you see as well as their colors.

2. Measure Each line you see has a wavelength. The prominent violet line has a wavelength of 436 nm and the prominent green line has a wavelength of 546 nm. How many mm apart are these lines on the paper? By how many nm do their wavelengths differ? How many nanometers of wavelength are represented by each millimeter you measured?

3. Calculate Using the nm/mm value you calculated and the mm distance you measured for each line from the violet reference line, calculate the wavelengths of all the other lines you see.

4. Calculate Use the wavelength value of each line to calculate its frequency given that $\nu = c/\lambda$ where $c = 2.998 \times 10^{17}$ nm/s (2.998×10^{8} m/s).

5. Calculate The energy E of a quantum of light an atom emits is related to its frequency ν by $E = h\nu$. Use the frequency value for each line and $h = 6.626 \times 10^{-34}$ J·s to calculate its corresponding energy.

You're the Chemist

1. Design an Experiment Design and carry out an experiment to measure the longest and shortest wavelengths you can see in daylight. Use your spectroscope to observe light from daylight reflected off a white piece of paper. **CAUTION** *Do not look directly at the sun!* Describe the differences in daylight and fluorescent light.

2. Design an Experiment Design and carry out an experiment to determine the effect of colored filters on the spectrum of fluorescent light or daylight. For each filter, tell which colors are transmitted and which are absorbed.

3. Analyze Data Use your spectroscope to observe various atomic emission discharge tubes provided by your teacher. Note and record the lines you see and measure their wavelengths.

Focus on ELL

4 LANGUAGE PRODUCTION Consider restating the procedure of the lab into numbered steps or directions. Have students work in groups of four to complete the lab. Make sure each group has ELLs of varied language proficiencies, so that more proficient students can help less proficient ones. Have students work according to their proficiency level.

BEGINNING: LOW/HIGH Paraphrase orally the procedural steps and group students with higher language proficiency partners.

INTERMEDIATE: LOW/HIGH Have students brainstorm what they think they may observe, prior to performing each step. Allow students to orally present their results.

ADVANCED: LOW/HIGH Have students write a couple of paragraphs explaining their procedure, findings, and results.

Explore

OBJECTIVE After completing this activity, students will be able to build a simple spectroscope and use it to determine wavelength, frequency, and energy of emission lines.

PREP TIME 10 minutes

CLASS TIME 20 minutes

TEACHING TIPS Have a completed spectroscope for students to examine. Have students bring in their own cereal boxes. Use holographic diffraction gratings of about 700 lines per millimeter. The diffraction grating needs to be positioned so that the lines on the grating are parallel to the slit. Very narrow slits do not let in enough light to see a bright spectrum.

EXPECTED OUTCOME Students calculate the wavelength, frequency, and energy of emissions from a fluorescent light.

ANALYZE

1. Most fluorescent lights display 5 lines: violet, blue, green, yellow and red. All fluorescent lights display violet, green and yellow. Older lights will display only two distinct violet and blue lines. A diffuse yellow line is also evident.
2. A typical box will yield a measurement of 30 mm between the violet and green lines; 546 – 436 = 110 nm; 110 nm/30 mm = 3.67 nm/mm
3. Blue: 436 nm + (16 mm × 3.67 nm/mm) = 495 nm; Green: 436 nm + (30 mm × 3.67 nm/mm) = 546 nm; Yellow: 436 nm + (42 × 3.67 nm/mm) = 590 nm; Red: 436 nm + (50 × 3.67 nm/mm) = 620 nm
4. Violet: $\nu = 3.00 \times 10^{17}$ nm/s436 nm = 6.88×10^{14} s^{-1}; Blue: $\nu = 3.00 \times 10^{17}$ nm/s495 nm = 6.06×10^{14} s^{-1}; Green: $\nu = 3.00 \times 10^{17}$ nm/s/546 nm = 5.49×10^{14} s^{-1}; Yellow: $\nu = 3.00 \times 10^{17}$ nm/s/590 nm = 5.08×10^{14} s^{-1}; Red: $\nu = 3.00 \times 10^{17}$ nm/s/620 nm = 4.84×10^{14} s^{-1}
5. Violet: 6.63×10^{-34} J · s × 6.88×10^{14} s^{-1} = 4.56×10^{-19} J; Blue: 6.63×10^{-34} J · s × 6.06×10^{14} s^{-1} = 4.02×10^{-19} J; Green: 6.63×10^{-34} J · s × 5.49×10^{14} s^{-1} = 3.64×10^{-19} J; Yellow: 6.63×10^{-34} J · s × 5.08×10^{14} s^{-1} = 3.37×10^{-19} J; Red: 6.63×10^{-34} J · s × 4.84×10^{14} s^{-1} = 3.21×10^{-19} J

YOU'RE THE CHEMIST

1. Sunlight has more red and more violet and lacks the distinct mercury emission lines of fluorescent light. Typical measurements are: Violet line to edge of red = 59 mm; 436 nm + (59 mm × 3.67 nm/mm) = 653 nm
   Violet line to edge of violet = – 4 mm; 436 nm – (4 × 3.67) nm/mm = 421 nm
2. Translucent colored file tabs from an office supply store work well as filters. A yellow filter transmits green, yellow, orange and red and absorbs violet and blue. A green filter transmits blue, green and yellow and absorbs violet, orange and red. A blue filter transmits violet, blue and green and absorbs yellow, orange and red. A red filter transmits yellow, orange and red and absorbs violet, blue and green.
3. Answers will vary. Provide students with gas discharge tubes containing hydrogen and noble gases.

Review and Assessment Resources

WALK-THRU TUTORIALS Each of the Math Tune-Up problems on the following page has an animated step-by-step tutorial that explains the problem-solving strategy in detail.

PROBLEM SETS Have students practice more problems using the Chapter 5 Online Problem Set.

MATH SKILLS Have struggling students practice manipulating algebraic equations using the MathXL learning module.

VIRTUAL LABS Have students complete a virtual lab as an in-class or take home assignment to help reinforce their understanding of the photoelectric effect and atomic emission spectra. To investigate the relationship between the color of light emitted and the identity of an element, assign the labs Flame Tests for Metals and Photoelectric Effect in **Virtual ChemLab**. To investigate atomic emission spectra, assign the labs Atomic Emission Spectra and Diffraction Experiments. Assign the lab Electronic State Energy Levels in **Virtual ChemLab** to reinforce electron configuration concepts.

Study Tip

SUMMARIZE Summarizing requires students to identify key ideas and state them briefly in their own words. Tell students that they will remember the content of an entire section better even if they summarize only a portion of the section.

5 Study Guide

BIG IDEA ELECTRONS AND THE STRUCTURE OF ATOMS

The quantum mechanical model of the atom comes from the solutions to the Schrödinger equation. Solutions to the Schrödinger equation give the energies an electron can have and the atomic orbitals, which describe the regions of space where an electron may be found. Electrons can absorb energy to move from one energy level to a higher energy level. When an electron moves from a higher energy level back down to a lower energy level, light is emitted.

5.1 Electrons and the Atomic Model

- Bohr proposed that an electron is found only in specific circular paths, or orbits, around the nucleus.
- The quantum mechanical model determines the allowed energies an electron can have and how likely it is to find the electron in various locations around the nucleus.
- Each energy sublevel corresponds to one or more orbitals of different shapes. The orbitals describe where an electron is likely to be found.

- energy level (129)
- quantum (129)
- quantum mechanical model (130)
- atomic orbital (131)

5.2 Electron Arrangement in Atoms

- Three rules—the aufbau principle, the Pauli exclusion principle, and Hund's rule—tell you how to find the electron configurations of atoms.

- electron configuration (134)
- aufbau principle (134)
- Pauli exclusion principle (134)
- spin (134)
- Hund's rule (134)

5.3 Atomic Emission Spectra and the Quantum Mechanical Model

- When atoms absorb energy, their electrons move to higher energy levels. These electrons lose energy by emitting light when they return to lower energy levels.
- To explain the photoelectric effect, Einstein proposed that light could be described as quanta of energy that behave as if they were particles.
- The light emitted by an electron moving from a higher to a lower energy level has a frequency directly proportional to the energy change of the electron.
- Classical mechanics adequately describes the motions of bodies much larger than atoms, while quantum mechanics describes the motions of subatomic particles and atoms as waves.

- amplitude (138)
- wavelength (138)
- frequency (138)
- hertz (138)
- electromagnetic radiation (139)
- spectrum (139)
- atomic emission spectrum (140)
- Planck's constant (143)
- photoelectric effect (143)
- photon (143)
- ground state (145)
- Heisenberg uncertainty principle (148)

Key Equations

$$c = \lambda\nu$$

$$E = h\nu$$

UbD Performance Tasks

MODEL MAKERS: Have students compare and contrast the three different electron models in a five paragraph essay. Students should include the scientist associated with each model, the reason why each model was accepted, and the reasons why a new model was needed.

SEEING THE LIGHT: In a computer slideshow presentation, explain the atomic emission spectrum. Then have students describe how they would make use of the spectrum to create either a colored light sign or a fireworks display.

Math Tune-Up: Atomic Emission Spectra and Photons

Problem

Calculate the wavelength of radiation with a frequency of 8.43×10^9 Hz (8.43×10^9/s). In what region of the electromagnetic spectrum is this radiation?

What is the energy of a photon of X-ray radiation with a frequency of 7.49×10^{18}/s?

1 Analyze

Knowns:
$\nu = 8.43 \times 10^9$/s
$c = 2.998 \times 10^8$ m/s

Unknown:
$\lambda = ?$ m

Use the equation that relates the frequency and wavelength of light:
$c = \lambda\nu$

Knowns:
$\nu = 7.49 \times 10^{18}$/s
$h = 6.626 \times 10^{-34}$ J·s

Unknown:
$E = ?$ J

Use the equation that relates the energy of a photon of radiation and the frequency of the radiation:
$E = h\nu$

2 Calculate

Solve for λ and calculate.

$$\lambda = \frac{c}{\nu}$$

$$\lambda = \frac{2.998 \times 10^8 \text{ m/s}}{8.43 \times 10^9 \text{/s}}$$

$\lambda = 3.56 \times 10^{-2}$ m

The radiation is in the radar region of the electromagnetic spectrum.

Substitute the known values for ν and h into the equation and calculate.

$E = (6.626 \times 10^{-34} \text{ J·s}) \times (7.49 \times 10^{18} \text{/s})$

$E = 4.96 \times 10^{-15}$ J

If you are given the wavelength of the radiation, first calculate frequency using $c = \lambda\nu$, and then use $E = h\nu$ to calculate energy.

3 Evaluate

The magnitude of the frequency of the radiation is larger than the value for the speed of light, so the answer should be less than 1.

Individual photons have very small energies, so the answer is reasonable.

Hint: Review Sample Problem 5.2 if you have trouble with converting between wavelength and frequency.

Math Review

Example and sample practice problems for the various electron problems can be found on the following pages:

LESSON 5.2 Writing Electron Configurations—page 136

LESSON 5.3 Calculating the Wavelength of Light—page 141; Calculating the Energy of a Photon—page 144

Focus on ELL

5 ASSESS UNDERSTANDING Preview the questions in the chapter assessment. Have students underline the words they don't understand. Review these words by referring to the word wall, bilingual glossary, or dictionary.

BEGINNING: LOW/HIGH Allow students to use their glossary during the assessment.

INTERMEDIATE

LOW Paraphrase or reread the assessment questions.

HIGH Encourage students to skip the questions they are unsure of and to go back to those once they have answered the questions they know.

ADVANCED: LOW/HIGH Encourage students to use good test taking strategies, like eliminating obvious distracters.

ASSESSMENT

Answers

LESSON 5.1

27. He used existing ideas about the atom to propose that electrons move around the nucleus like the planets move around the sun.

28. that electrons traveled in circular paths around the nucleus

29. In Rutherford's model, negatively charged electrons surround a dense, positively charged nucleus. In Bohr's model, the electrons are assigned to concentric circular orbits of fixed energy.

30. An electron is found 90% of the time inside this boundary.

31. a region in space around the nucleus in which there is a high probability of finding an electron

32. The 1*s* orbital is spherical. The 2*s* orbital is spherical with a diameter larger than that of the 1*s* orbital. The three 2*p* orbitals are dumbbell shaped and oriented at right angles to each other.

33. 3

34. **a.** 1 **b.** 2 **c.** 3 **d.** 4

LESSON 5.2

35. Electrons occupy the lowest possible energy levels. An atomic orbital can hold at most two electrons. One electron occupies each of a set of orbitals with equal energies before any pairing of electrons occurs.

36. 2*s*, 3*p*, 4*s*, 3*d*

37. **b** and **c**

38. **a.** 2 **c.** 6 **e.** 6 **g.** 2
b. 2 **d.** 14 **f.** 10 **h.** 6

39. The *p* orbitals in the third quantum level have three electrons.

40. **a.** $1s^2 2s^2 2p^3$
b. $1s^2 2s^2 2p^5$
c. $1s^2 2s^2 2p^6 3s^2$
d. $1s^2 2s^2 2p^6 3s^2 3p^6 3d^{10} 4s^2 4p^6$

41. **a.** $1s^2 2s^2 2p^6 3s^1$
b. $1s^2 2s^2 2p^6 3s^2 3p^6 4s^1$
c. $1s^2 2s^2 2p^6 3s^2 3p^6 3d^{10} 4s^2 4p^6 4d^{10} 5s^2 5p^5$
d. $1s^2 2s^2 2p^6$

42. **a.** 2 **b.** 3 **c.** 1 **d.** 6

43. **a.** 8 **b.** 8 **c.** 8

44. **a.** $1s^2 2s^2 2p^6 3s^2 3p^6 3d^{10} 4s^2 4p^4$
b. $1s^2 2s^2 2p^6 3s^2 3p^6 3d^2 4s^2$
c. $1s^2 2s^2 2p^6 3s^2 3p^6 3d^3 4s^2$
d. $1s^2 2s^2 2p^6 3s^2 3p^6 4s^2$

5 Assessment

* Solutions appear in Appendix E

Lesson by Lesson

5.1 Revising the Atomic Model

27. Why was Rutherford's model of the atom known as the planetary model?

***28.** What did Bohr assume about the motion of electrons?

29. Describe Rutherford's model of the atom and compare it with the model proposed by his student Niels Bohr.

***30.** What is the significance of the boundary of an electron cloud?

31. What is an atomic orbital?

32. Sketch 1*s*, 2*s*, and 2*p* orbitals using the same scale for each.

***33.** How many orbitals are in the 2*p* sublevel?

***34.** How many sublevels are contained in each of these principal energy levels?
a. $n = 1$ **c.** $n = 3$
b. $n = 2$ **d.** $n = 4$

5.2 Electron Arrangement in Atoms

***35.** What are the three rules that govern the filling of atomic orbitals by electrons?

***36.** Arrange the following sublevels in order of increasing energy:
3*d*, 2*s*, 4*s*, 3*p*.

***37.** Which of these orbital designations are invalid?
a. 4*s* **c.** 3*f*
b. 2*d* **d.** 3*p*

38. What is the maximum number of electrons that can go into each of the following sublevels?
a. 2*s* **e.** 3*p*
b. 4*s* **f.** 3*d*
c. 4*p* **g.** 5*s*
d. 4*f* **h.** 5*p*

***39.** What is meant by $3p^3$?

40. Write electron configurations for the elements that are identified by these atomic numbers:
a. 7 **c.** 12
b. 9 **d.** 36

41. Give electron configurations for atoms of these elements:
a. Na **c.** I
b. K **d.** Ne

***42.** How many electrons are in the highest occupied energy level of these atoms?
a. barium **c.** sodium
b. aluminum **d.** oxygen

43. How many electrons are in the second energy level of an atom of each element?
a. chlorine
b. phosphorus
c. potassium

***44.** Write electron configurations for atoms of these elements:
a. selenium **c.** vanadium
b. titanium **d.** calcium

5.3 Atomic Emission Spectra and the Quantum Mechanical Model

45. Use a diagram to illustrate each term for a wave.
a. wavelength
b. amplitude
c. cycle

46. What is meant by the frequency of a wave? What are the units of frequency? Describe the relationship between frequency and wavelength.

***47.** Consider the following regions of the electromagnetic spectrum: (i) ultraviolet, (ii) X-ray, (iii) visible, (iv) infrared, (v) radio wave, (vi) microwave.
a. Use Figure 5.8 to arrange them in order of decreasing wavelength.
b. How does this order differ from that of decreasing frequency?

48. List the colors of the visible spectrum in order of increasing wavelength.

49. How did Planck influence the development of modern atomic theory?

***50.** Explain the difference between a photon and a quantum.

***51.** What has more energy, a photon of infrared light or a photon of ultraviolet light?

LESSON 5.3

45. diagrams similar to those in Figure 5.7

46. Frequency is the number of wave cycles that pass a given point per unit time. Frequency units are cycles/s or s^{-1} or Hertz. Wavelength and frequency are inversely related.

47. **a.** v, vi, iv, iii, i, ii
b. It is the reverse.

48. Violet, indigo, blue, green, yellow, orange, red

49. He showed mathematically that the amount of radiant energy (E) of a single quantum absorbed or emitted by a body is proportional to the frequency of radiation (ν).

50. A quantum is a discrete amount of energy. Photons are light quanta.

51. A photon of ultraviolet light has a higher frequency (smaller wavelength) than a photon of infrared light. Therefore, a photon of ultraviolet light has more energy than a photon of infrared light.

*52. What is the energy of a photon of green light with a frequency of 5.80×10^{14}/s?

*53. Explain the difference between the energy lost or gained by an atom according to the laws of classical physics and according to the quantum model of the atom.

*54. What happens when a hydrogen atom absorbs a quantum of energy?

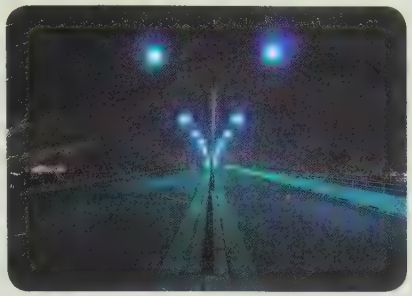
55. The transition of electrons from higher energy levels to the $n = 2$ energy level results in the emission of light from hydrogen atoms. In what part of the spectrum is the emitted light, and what is the name given to this transition series?

Understand Concepts

56. Give the symbol for the atom that corresponds to each electron configuration.
   a. $1s^2 2s^2 2p^6 3s^2 3p^6$
   b. $1s^2 2s^2 2p^6 3s^2 3p^6 3d^{10} 4s^2 4p^6 4d^7 5s^1$
   c. $1s^2 2s^2 2p^6 3s^2 3p^6 3d^{10} 4s^2 4p^6 4d^{10} 4f^7 5s^2 5p^6 5d^1 6s^2$

*57. Write the electron configuration for an arsenic atom. Calculate the total number of electrons in each energy level and state which energy levels are not full.

58. How many paired electrons are there in an atom of each element?
   a. helium
   b. sodium
   c. boron
   d. oxygen



*59. An atom of an element has two electrons in the first energy level and five electrons in the second energy level. Write the electron configuration for this atom and name the element. How many unpaired electrons does an atom of this element have?

*60. Give the symbols and names of the elements that correspond to these configurations of an atom.
   a. $1s^2 2s^2 2p^6 3s^1$
   b. $1s^2 2s^2 2p^3$
   c. $1s^2 2s^2 2p^6 3s^2 3p^2$
   d. $1s^2 2s^2 2p^4$
   e. $1s^2 2s^2 2p^6 3s^2 3p^6 4s^1$
   f. $1s^2 2s^2 2p^6 3s^2 3p^6 3d^2 4s^2$

61. What is the maximum number of electrons that can be found in any orbital of an atom?

62. Suppose your favorite AM radio station broadcasts at a frequency of 1150 kHz. What is the wavelength, in centimeters, of the radiation from the station?

*63. A mercury lamp, such as the one below, emits radiation with a wavelength of 4.36×10^{-7} m.

   a. What is the wavelength of this radiation in centimeters?
   b. In what region of the electromagnetic spectrum is this radiation?
   c. Calculate the frequency of this radiation.

64. Sodium vapor lamps are used to illuminate streets and highways. The very bright light emitted by these lamps is actually due to two closely spaced emission lines in the visible region of the electromagnetic spectrum. One of these lines has a wavelength of 5.890×10^{-7} m, and the other line has a wavelength of 5.896×10^{-7} m.
   a. What are the wavelengths of these radiations in centimeters?
   b. Calculate the frequencies of these radiations.
   c. In what region of the visible spectrum do these lines appear?

*65. What will happen if the following occur?
   a. Monochromatic light shining on cesium metal is just above the threshold frequency.
   b. The intensity of the light increases, but the frequency remains the same.
   c. Monochromatic light of a shorter wavelength is used.

*66. Calculate the energy of a photon of red light with a wavelength of 6.45×10^{-5} cm. Compare your answer with the answer to Question 52. Is red light of higher or lower energy than green light?

Answers

52. 3.84×10^{-19} J

53. Classical physics views energy changes as continuous. In the quantum concept, energy changes occur in tiny discrete units called quanta.

54. The electron of the hydrogen atom is raised (excited) to a higher energy level.

55. visible spectrum, Balmer series

UNDERSTAND CONCEPTS

56. a. Ar b. Ru c. Gd

57. $1s^2 2s^2 2p^6 3s^2 3p^6 3d^{10} 4s^2 4p^3$; level 1, 2; level 2, 8; level 3, 18; level 4, 5; The fourth energy level is not filled.

58. a. 2 b. 10 c. 4 d. 6

59. $1s^2 2s^2 2p^3$ nitrogen; 3

60. a. Na, sodium
   b. N, nitrogen
   c. Si, silicon
   d. O, oxygen
   e. K, potassium
   f. Ti, titanium

61. 2

62. 2.61×10^4 cm

63. a. 4.36×10^{-5} cm b. visible c. $6.88 \times 10^{14} s^{-1}$

64. a. 5.890×10^{-5} cm and 5.896×10^{-5} cm
   b. 5.090×10^{14} s^{-1} (Hz) and 5.085×10^{14} s^{-1} (Hz)
   c. yellow

65. a. Electrons with a low velocity will be emitted.
   b. More electrons will be emitted but with a low velocity.
   c. Electrons will be emitted with a higher velocity.

66. 3.08×10^{-19} J; Red light is lower energy than green light.

ASSESSMENT

Evaluate

Answers

67. It is not possible to know both the position and the velocity of a particle at the same time.

68. The frequency is inversely proportional to the wavelength, so if the frequency increases by a factor of 1.5, the wavelength will decrease by a factor of 1.5.

69. emits: a; absorbs: b, c and d

70. The outermost electron of sodium absorbs photons of wavelength 589 nm as it jumps to a higher energy level.

71. 1.57×10^{-24} J

72. **a.** 1.7×10^{-21} J **b.** 3.9×10^{-19} J
c. 1.7×10^{-17} J; The energy of the photon of light increases as its wavelength decreases.

THINK CRITICALLY

73. An orbit confines the electron to a fixed circular path around the nucleus; an orbital is a region around the nucleus in which electrons are likely to be found.

74. **a.** fluorine **b.** germanium **c.** vanadium

75. Answers will vary. Some students may note that radio waves have the lowest energy in the electromagnetic spectrum, and thus would not be energetic enough to cook food. Others may reason that if microwaves cook food faster than infrared radiation, then radio waves would cook food even faster.

76. Answers will vary. The model of the atom is based on the abstract idea of probability. Light is considered a particle and a wave at the same time. Atoms and light cannot be compared to familiar objects or observations because humans cannot experience atoms or photons directly and because matter and energy behave differently at the atomic level than at the level humans can observe directly.

77. **a.** Electrons in 2*p* boxes should not be paired—there should be one electron in each.
b. Magnesium has 12 electrons. Two more electrons need to be added to 3*s*.

78. **a.** $n = 1$ level
b. $n = 4$ level
c. $n = 4$ level
d. $n = 1$ level

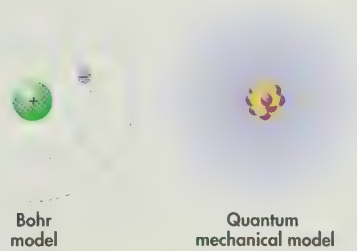
79. **a.** potassium, excited state, valence electron has been promoted from 4*s* to 5*p*
b. potassium, ground state, correct electron configuration
c. impossible configuration, 3*p* orbitals can hold a maximum of 6 electrons, not 7

80. The electrons obey Hund's rule.

67. State the Heisenberg uncertainty principle.

68. Describe how the wavelength of a wave changes if the frequency of the wave is multiplied by 1.5.

***69.** Indicate whether each of the following electron transitions emits energy or requires the absorption of energy.
a. 3*p* to 3*s**c.** 2*s* to 2*p*
b. 3*p* to 4*p**d.** 1*s* to 2*s*



***70.** White light is viewed in a spectroscope after passing through sodium vapor too cool to emit light. The spectrum is continuous except for a dark line at 589 nm. How can you explain this observation? (*Hint:* Recall from Sample Problem 5.2 that the atomic emission spectrum of sodium exhibits a strong yellow line at 589 nm.)

71. You use a microwave oven to heat your dinner. The frequency of the radiation is $2.37 \times 10^{9}\ s^{-1}$. What is the energy of one photon of this radiation?

***72.** Calculate the following energies:
a. One photon of infrared radiation, if $\lambda = 1.2 \times 10^{-4}$ m.
b. One photon of visible radiation, if $\lambda = 5.1 \times 10^{-7}$ m.
c. One photon of ultraviolet radiation, if $\lambda = 1.4 \times 10^{-8}$ m.
What do the answers indicate about the relationship between the energy of light and its wavelength?

Think Critically

***73.** **Compare** Explain the difference between an orbit in the Bohr model and an orbital in the quantum mechanical model of the atom.

Bohr model

Quantum mechanical model

74. **Apply Concepts** Identify the elements whose electrically neutral atoms have the following electron configurations.
a. $1s^2 2s^2 2p^5$
b. $1s^2 2s^2 2p^6 3s^2 3p^6 3d^{10} 4s^2 4p^2$
c. $1s^2 2s^2 2p^6 3s^2 3p^6 3d^3 4s^2$

***75.** **Predict** Traditional cooking methods make use of infrared radiation (heat). Microwave radiation cooks food faster. Could radio waves be used for cooking? Explain.

76. **Draw Conclusions** Think about the currently accepted models of the atom and of light. In what ways do these models seem strange to you? Why are these models not exact or definite?

77. **Evaluate and Revise** Orbital diagrams for the ground states of two elements are shown below. Each diagram shows something that is incorrect. Identify the error in each diagram and then draw the correct diagram.
a. Nitrogen

1*s*	2*s*	2*p*
↑↓	↑↓	↑↓ ↑ ☐

b. Magnesium

1*s*	2*s*	2*p*	3*s*
↑↓	↑↓	↑↓ ↑↓ ↑↓	☐

***78.** **Infer** Picture two hydrogen atoms. The electron in the first hydrogen atom is in the $n = 1$ level. The electron in the second atom is in the $n = 4$ level.
a. Which atom has the ground state electron configuration?
b. Which atom can emit electromagnetic radiation?
c. In which atom is the electron in a larger orbital?
d. Which atom has the lower energy?

***79.** **Infer** Which of the following is the ground state of an atom? Which is its excited state? Which is an impossible electron configuration? Identify the element and briefly explain your choices.
a. $1s^2 2s^2 2p^6 3s^2 3p^6 5p^1$
b. $1s^2 2s^2 2p^6 3s^2 3p^6 4s^1$
c. $1s^2 2s^2 2p^6 3s^2 3p^7$

80. **Relate Cause and Effect** Why do electrons occupy equal energy orbitals singly before beginning to pair up?

Enrichment

*81. **Graph** The energy of a photon is related to its frequency and its wavelength.

Energy of photon (J)	Frequency (s^{-1})	Wavelength (cm)
3.45×10^{-21}	ν_1 _____	5.77×10^{-3}
2.92×10^{-20}	ν_2 _____	6.82×10^{-4}
6.29×10^{-20}	ν_3 _____	3.16×10^{-4}
1.13×10^{-19}	ν_4 _____	1.76×10^{-4}
1.46×10^{-19}	ν_5 _____	1.36×10^{-4}
3.11×10^{-19}	ν_6 _____	6.38×10^{-5}

a. Complete the table above.
b. Plot the energy of the photon (y-axis) versus the frequency (x-axis).
c. Determine the slope of the line.
d. What is the significance of this slope?

82. **Calculate** The average distance between Earth and Mars is about 2.08×10^8 km. How long would it take to transmit television pictures from Mars to Earth?

*83. **Calculate** Bohr's atomic theory can be used to calculate the energy required to remove an electron from an orbit of a hydrogen atom or an ion (an atom that has lost or gained electrons) containing only one electron. This number is the ionization energy for that atom or ion. The formula for determining the ionization energy (E) is

$$E = Z^2 \times \frac{k}{n^2}$$

where Z is the atomic number, k is 2.18×10^{-18} J, and n is the energy level. What is the energy required to eject an electron from a hydrogen atom when the electron is in the ground state ($n = 1$)? In the second energy level? How much energy is required to eject a ground state electron from the species Li^{2+} (a lithium atom that has lost two electrons)?

84. **Draw Conclusions** In a photoelectric experiment, a student shines light on the surface of a metal. The frequency of the light is greater than the threshold frequency of the metal. The student observes that after a long time, the maximum energy of the ejected electrons begins to decrease. Explain this observation.

Write About Science

*85. **Explain** Write a brief description of how trying to place two bar magnets pointing in the same direction alongside each other is like trying to place two electrons into the same orbital.

86. Connect to the **BIG**IDEA The late 1800s and early 1900s were significant times for the rapid development of chemistry. Bohr improved on Rutherford's model of the atom, then Schrödinger developed the quantum mechanical model of the atom. Explain why a model of the atom is crucial to understanding chemistry and in explaining the behavior of matter.

CHEMYSTERY

Now You See It... Now You Don't

Liam eventually realized that his star stickers would always stop glowing after a period of time. He discovered that he could "recharge" the stickers by turning on the lights. After he turned off the lights, the stars would glow again. However, after a few hours, the stars would eventually stop glowing.

Glow-in-the-dark objects contain compounds that react with light. When these objects are exposed to light, the electrons in the compounds absorb energy and become excited. As the electrons drop back down to a lower energy level, they emit light. This process, called phosphorescence, occurs more slowly in the compounds contained in glow-in-the-dark objects than in other compounds.

87. **Infer** Do Liam's glow-in-the-dark stars glow when the lights are on? Explain.

*88. Connect to the **BIG**IDEA Light emitted from an incandescent light bulb is in the visible region of the electromagnetic spectrum (300 nm to 700 nm). What does this information tell you about the energy of the photons absorbed by the electrons in glow-in-the dark objects?

CHEMISTRY & YOU

SUMMARIZE After students have read through the CHEMystery, call on volunteers to summarize how the behavior of electrons helps explain the glow-in-the-dark stars in Liam's bedroom. **Ask** Why do the stars glow in the dark for only a short period of time? **Answer:** *(The stars glow after they have been exposed to light because the atoms absorbed energy. This resulted in the electrons moving into higher energy levels. When it is dark, the electrons lose energy and return to a lower energy level, resulting in a gradual fading of the light.)* **Ask** What caused the stars to start glowing again? *(The light in the room was turned on which allowed the atoms in the stars to absorb energy. The electrons moved into higher energy levels, resulting in the star's ability to glow in the dark once again.)*

CHEMYSTERY ANSWERS

87. No. As long as the lights are on the atoms in the stars are absorbing energy, and the electrons remain in their higher energy levels. Once the lights are turned off, the atoms are no longer absorbing energy and the electrons can drop to lower energy levels, emitting light in the process.

88. **BIG**IDEA The light emitted from an incandescent bulb has wavelengths from 300 nm to 700 nm, which corresponds to a frequency range of about 4×10^{14} s^{-1} to 1×1015 s^{-1}. This means that the energy absorbed by the photons is in the range of about 3×10^{-19} J to 7×10^{-19} J.

Answers

CUMULATIVE REVIEW

89. **a** and **b** are heterogeneous; **c** is homogeneous

90. Answers will vary but could include: water is lost as steam and burned meat gives off carbon dioxide.

91. A compound has constant composition; the composition of a mixture can vary.

92. a heterogeneous mixture

93. 7.7×10^{-5} μm

94. 18.9 cm^3

95. the piece of lead

96. **a.** 3.9×10^{-5} kg
b. 7.84×10^{2} L
c. 8.30×10^{-2} g
d. 9.7×10^{6} ng

97. **a** and **b** are exact

98. Mass remains the same; weight decreases because gravity on moon is less than gravity on earth.

99. 8.92 g/cm^3

100. 154 g, 1.54×10^{-1} kg

101. Helium gas is less dense than the nitrogen gas and oxygen gas in the air.

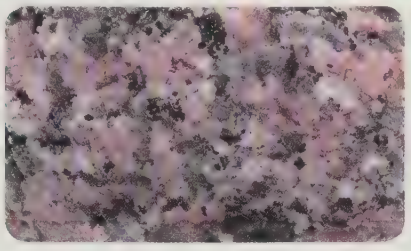
102. Accuracy is a measure of how close the value is to the true value; precision is a measure of how close a series of measurements are to one another.

103. **a.** 55 protons, 55 electrons
b. 47 protons, 47 electrons
c. 48 protons, 48 electrons
d. 34 protons, 34 electrons

104. a

105. Neon-20 has 10 neutrons; neon-21 has 11 neutrons.

106. The value 35.453 amu is a weighted average. Its calculation is based on the percentage natural abundance of two isotopes, chlorine-35 and chlorine-37.



Cumulative Review

***89.** Classify each of the following as homogeneous or heterogeneous:
a. a page of this textbook
b. a banana split
c. the water in bottled water

90. Hamburger undergoes a chemical change when cooked on a grill. All chemical changes are subject to the law of conservation of mass. Yet, a cooked hamburger will weigh less than the uncooked meat patty. Explain.

***91.** Homogeneous mixtures and compounds are both composed of two or more elements. How do you distinguish between a homogeneous mixture and a compound?

92. The photo shows a magnified view of a piece of granite. Is granite a substance or a mixture?

***93.** The diameter of a carbon atom is 77 pm. Express this measurement in μm.

94. A silver bar has a mass of 368 g. What is the volume, in cm^3, of the bar? The density of silver is 19.5 g/cm^3.

***95.** Which has more mass, a 28.0-cm^3 piece of lead or a 16.0-cm^3 piece of gold? The density of lead is 11.4 g/cm^3; the density of gold is 19.3 g/cm^3.

96. Express the following measurements in scientific notation.
a. 0.000039 kg
b. 784 L
c. 0.0830 g
d. 9,700,000 ng

97. Which of these quantities or relationships are exact?
a. 10 cm = 1 dm
b. There are 9 baseball players on the field.
c. A diamond has a mass of 12.4 g.
d. The temperature is 21°C.

98. A one-kilogram steel bar is brought to the moon. How are its mass and its weight each affected by this change in location? Explain.

***99.** When a piece of copper with a mass of 36.4 g is placed into a graduated cylinder containing 20.00 mL of water, the water level rises to 24.08 mL, completely covering the copper. What is the density of copper?

100. The density of gold is 19.3 g/cm^3. What is the mass, in grams, of a cube of gold that is 2.00 cm on each edge? In kilograms?

***101.** A balloon filled with helium will rise upward when released. What does this result show about the relative densities of helium and air?

***102.** Explain the difference between the accuracy of a measurement and the precision of a measurement.

103. Give the number of protons and electrons in each of the following:
a. Cs
b. Ag
c. Cd
d. Se

104. Which of these was an essential part of Dalton's atomic model?
a. indivisible atoms
b. electrons
c. atomic nuclei
d. neutrons

***105.** How do neon-20 and neon-21 differ from each other?

106. The mass of an atom should be very nearly the sum of the masses of its protons and neutrons. The mass of a proton and the mass of a neutron are each very close to 1 amu. Why is the atomic mass of chlorine, 35.453 amu, so far from a whole number?

Standardized Test Prep for Indiana

Standard: C.2.2

Select the choice that best answers each question or completes each statement.

Tips for Success

Eliminate Wrong Answers If you don't know which response is correct, start by eliminating those you know are wrong. If you can rule out some choices, you'll have fewer left to consider and you'll increase your chances of choosing the correct answer.

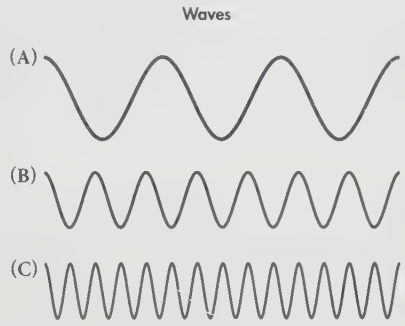
1. Select the correct electron configuration for silicon, atomic number 14.
   (A) $1s^2 2s^2 2p^2 3s^2 3p^2 3d^2 4s^2$
   (B) $1s^2 2s^2 2p^4 3s^2 3p^4$
   (C) $1s^2 2s^6 2p^6$
   (D) $1s^2 2s^2 2p^6 3s^2 3p^2$

2. Which two orbitals have the same shape?
   (A) 2*s* and 2*p*
   (B) 2*s* and 3*s*
   (C) 3*p* and 3*d*
   (D) More than one is correct.

3. Which of these statements characterize the nucleus of every atom?
   I. It has a positive charge.
   II. It is very dense.
   III. It is composed of protons, electrons, and neutrons.
   (A) I and II only
   (B) II and III only
   (C) I and III only
   (D) I, II, and III

4. As the wavelength of light increases,
   (A) the frequency increases.
   (B) the speed of light increases.
   (C) the energy decreases.
   (D) the intensity increases.

5. In the third energy level of an atom,
   (A) there are two energy sublevels.
   (B) the *f* sublevel has 7 orbitals.
   (C) there are three *s* orbitals.
   (D) a maximum of 18 electrons are allowed.



The lettered choices below refer to Questions 6–10. A lettered choice may be used once, more than once, or not at all.

(A) $s^2 p^6$ (B) $s^2 p^2$ (C) s^2 (D) $s^4 p^1$ (E) $s^2 p^4$

Which configuration is the configuration of the highest occupied energy level for each of these elements?

6. sulfur
7. germanium
8. beryllium
9. krypton
10. strontium

Use the drawings to answer Questions 11–14. Each drawing represents an electromagnetic wave.

11. Which wave has the longest wavelength?
12. Which wave has the highest energy?
13. Which wave has the lowest frequency?
14. Which wave has the highest amplitude?

Write a short essay to answer Question 15.

15. Explain the rules that determine how electrons are arranged around the nuclei of atoms.

IN ACADEMIC STANDARDS for SCIENCE

Nature of Science

- Use analogies and models (mathematical and physical) to simplify and represent systems that are difficult to understand or directly experience due to their size, time scale, or complexity, and recognize the limitations of analogies and models.
- Focus on the development of explanatory models based on their observations during laboratory investigations.

Also covered C.2.5, C.2.6.

Focus on ELL

1 CONTENT AND LANGUAGE Ask students to create a KWL chart. Have them complete the first column by writing everything they already know about the periodic table. Then have them use the Essential Questions and the CHEMystery to identify what they want to know. At the end of each lesson, have them identify what they learned.

BEGINNING: LOW/HIGH Allow students to work in pairs and use pictures or symbols to represent what they already know and make lists for what they want to know.

INTERMEDIATE: LOW/HIGH Encourage students to copy the information from the essential questions onto their chart.

ADVANCED: LOW/HIGH Tell students to read the CHEMystery feature and determine at least one thing that they want to learn from the reading.

BIGIDEA

ELECTRONS AND THE STRUCTURE OF ATOMS

Essential Questions:

1. *What information does the periodic table provide?*
2. *How can periodic trends be explained?*

CHEMYSTERY

Made in the USA

Only 90 elements in the periodic table are known to occur naturally. You might ask then, "Why are there more than a hundred elements listed in the periodic table?"

Between the years of 1940 and 1958, nine of these "unnatural" elements were discovered by the American scientist Glenn Seaborg and his colleagues at the University of California at Berkeley. Later in 1974, Seaborg and his team discovered yet another element. Several other "unnatural" elements were discovered by Russian and German scientists.

How do these elements compare to other elements in the periodic table?

▶ Connect to the BIGIDEA As you read about the periodic table, keep an eye out for elements that do not occur naturally.

INDIANA'S ACADEMIC STANDARDS FOR SCIENCE

Solutions C.2.5, C.2.6. See lessons for details.

Introduce the Chapter

IDENTIFYING PRECONCEPTIONS Most students have probably heard of the periodic table, but they may have a limited understanding of the information it contains. Use the activity below to assess students' level of knowledge about the periodic table.

Activity Divide the class into small groups. Provide each group with a sheet of paper on which the names of twenty of the most familiar elements of the periodic table are printed. Challenge students to organize the list into a table using any criteria they prefer. Each group should then present and explain the organization of their list to the class. Afterwards, describe to students some of the ways they will learn in this chapter that the periodic table is organized and is useful.

UbD

Understanding by Design

Students are building toward understanding the periodic table by applying a knowledge of electrons and the structure of atoms.

PERFORMANCE GOALS At the end of Chapter 6, students will be able to answer the essential questions by applying their knowledge of the periodic table. Students will also be able to write electron configurations for elements.

ESSENTIAL QUESTIONS Read the essential questions aloud. **Ask** What are some ways that elements are different from each other? *(Their atoms have different numbers of protons, and they have different electron configurations.)* **Ask** Why is it useful to organize information into a table? *(Sample answer: A table helps you to quickly see differences and similarities in things.)*

BIGIDEA Use the photo of sorted beads to help students connect to the concepts they will learn in this chapter. Activate prior knowledge by discussing with students the benefits of sorting things. Have them imagine how much harder it would be to find one of the beads in the photo if they were not sorted. Have students name things in their everyday lives that are sorted. Then point out that there are so many elements with different properties, sorting them helps you understand how they are alike and different.

CHEMYSTERY Have students read over the CHEMystery. Connect the CHEMystery to the Big Idea of Electrons and the Structure of Atoms by explaining that the "unnatural" elements were discovered because scientists were able to predict their existence by studying the atomic structure of known elements. Encourage students to predict how the "unnatural" elements are different from the other elements. As a hint, suggest that they consider what property an element might have that would make it unlikely to occur in nature.

LESSON 6.1

Key Objectives

- **6.1.1 EXPLAIN** how chemists began to organize the known elements.
- **6.1.2 DESCRIBE** how Mendeleev organized his periodic table.
- **6.1.3 DESCRIBE** how the modern periodic table is organized.
- **6.1.4 IDENTIFY** three broad classes of elements.

Engage

CHEMISTRY & YOU Have students look at the opening photograph and read the opening text. Have students list the types of characteristics that might be used to organize a group of cards as discussed in the text. Discuss as a class how these categories can then be subdivided.

Access Prior Knowledge

Have students recall what makes one element different from another. *(They contain different numbers of protons.)* **Ask** What is the term used to identify the number of protons in an element? *(atomic number)* Have students keep this in mind as they read this section.

IN ACADEMIC STANDARDS for SCIENCE

C.2.6 Use the periodic table and electron configurations to determine an element's number of valence electrons and chemical and physical properties.

6.1 Organizing the Elements

C.2.6 Determine valence electrons and properties

CHEMISTRY & YOU

Q: *How can you organize and classify elements?* If you have ever played a card game, then you have probably organized your cards. Maybe you classified them by color or number. Elements can also be classified. In this lesson, you will learn how elements are arranged in the periodic table and what that arrangement reveals about the elements.

Key Questions

- ***How did chemists begin to organize the known elements?***
- ***How did Mendeleev organize his periodic table?***
- ***How is the modern periodic table organized?***
- ***What are three broad classes of elements?***

Vocabulary

- periodic law • metal
- nonmetal • metalloid

Figure 6.1 Triad in Dobereiner's System Chlorine, bromine, and iodine formed one triad. These elements have similar chemical properties.

Searching for an Organizing Principle

How did chemists begin to organize the known elements?

A few elements, including copper, silver, and gold, have been known for thousands of years. Yet, there were only 13 elements identified by the year 1700. Chemists suspected that other elements existed. They had even assigned names to some of these elements, but they were unable to isolate the elements from their compounds. As chemists began to use scientific methods to search for elements, the rate of discovery increased. In one decade (1765–1775), chemists identified five new elements, including three colorless gases, hydrogen, nitrogen, and oxygen. Was there a limit to the number of elements? How would chemists know when they had discovered all the elements? To begin to answer these questions, chemists needed to find a logical way to organize the elements.

Early chemists used the properties of elements to sort them into groups. In 1829, a German chemist, J. W. Dobereiner (1780–1849), published a classification system. In his system, the known elements were grouped into triads. A triad is a set of three elements with similar properties. The elements in Figure 6.1 formed one triad. Chlorine, bromine, and iodine may look different, but they have very similar chemical properties. For example, they react easily with metals. Unfortunately, all the known elements could not be grouped into triads.

Dobereiner noted a pattern in his triads. One element in each triad tended to have properties with values that fell midway between those of the other two elements. For example, the average of the atomic masses of chlorine and iodine is [(35.453 1 + 126.90)/2] or 81.18 amu. This value is close to the atomic mass of bromine, which is 79.904 amu.

Focus on ELL

1 CONTENT AND LANGUAGE Have students create a four column chart. In the first column, have them copy the key questions and the vocabulary terms. Have students title the second column *Answer/Definition*, the third column, *Where can I find it?*, and the fourth column, *Do I know it?* As you proceed through the lesson, encourage students to fill in columns two and three. At the end of the lesson, ask students to self-assess their knowledge by filling in the fourth column; use this column to determine whether there is a need for reteaching.

2 FRONTLOAD THE LESSON Have students consider how information is organized on their MP3 players. For example, ask students how their contact lists playlists are organized and what information is available about each song. Explain that the periodic table lists all the elements by atomic number but that the resulting arrangement of the table groups the elements in different ways. Have students keep this in mind as they proceed with the lesson.

но въ ней, мнѣ кажется, уже ясно выражается примѣнимость выставляемаго мною начала ко всей совокупности элементовъ, свойствами которыхъ извѣстенъ съ достовѣрностію. На этотъ разъ я и желалъ преимущественно найдти общую систему элементовъ. Вотъ этотъ опытъ:

Figure 6.2
Mendeleev's Periodic Table
In this early version of the periodic table, Mendeleev (shown on the stamp below) arranged elements with similar properties in the same row.
Identify *Which element is grouped with chlorine (Cl), bromine (Br), and (I) iodine?*

Mendeleev's Periodic Table

How did Mendeleev organize his periodic table?

From 1829 to 1869, different systems for organizing the elements were proposed, but none of them gained wide acceptance. In 1869, a Russian chemist and teacher, Dmitri Mendeleev, published a table of the elements. Later that year, a German chemist, Lothar Meyer, published a nearly identical table. Mendeleev was given more credit than Meyer because he published his table first and because he was better able to explain its usefulness.

Mendeleev developed his table while working on a textbook for his students. He needed a way to show the relationships among more than 60 elements. He wrote the properties of each element on a separate note card. This approach allowed him to move the cards around until he found an organization that worked. The organization he chose was a periodic table. Elements in a periodic table are arranged into groups based on a set of repeating properties. **Mendeleev arranged the elements in his periodic table in order of increasing atomic mass.**

Figure 6.2 is an early version of Mendeleev's periodic table. Look at the column that starts with Ti = 50. Notice the two question marks between the entries for zinc (Zn) and arsenic (As). Mendeleev left these spaces in his table because he knew that bromine belonged with chlorine and iodine. He predicted that elements would be discovered to fill those spaces, and he predicted what their properties would be based on their locations in the table. The elements between zinc and arsenic were gallium and germanium, which were discovered in 1875 and 1886, respectively. There was a close match between the predicted properties and the actual properties of these elements. This match helped convince scientists that Mendeleev's periodic table was a powerful tool.

See more about organizing information.

Professional Development Note

Three-Dimensional Periodic Attempts

A table of atomic weights, along with letters to symbolize all known elements, was proposed in 1828, by Jöns Jakob Berzelius. In 1862, French geologist A. E. Beguyer de Chancourtois made use of the relationship between the elements and their atomic weights by representing their relationship on a geometric model. The model involved a listing of elements wrapped around a cylinder in specified intervals so that similar elements lined up. Although the model contained flaws, de Chancourtois is one of the first scientists to visually realize a reoccuring pattern among elemental properties.

Foundations for Reading

BUILD VOCABULARY Point out that *metal, nonmetal,* and *metalloid* all have the same root. Discuss the meanings of the suffix *-oid* (resembling) and prefix *non-* (not).

READING STRATEGY Have students write down the following terms at the top of a sheet of paper: *groups, periods, periodic law, periodic table, repeating properties, metals, nonmetals,* and *metalloids.* Instruct students to generate a concept map relating these terms as they progress through the chapter.

Explore

Searching For an Organizing Principle

Teacher Demo

PURPOSE To provide students with an understanding of how elements are organized.

MATERIALS samples of elements, or photographs of elements

PROCEDURE Display the samples of the elements or the photographs the elements. Ask students to use properties of the elements to organize them and to explain the organization.

Explain

Mendeleev's Periodic Table

USE VISUALS Have students study Mendeleev's version of the periodic table in Figure 6.2. Show students how the elements with similar chemical properties were arranged in rows. Point out the gaps in the table where Mendeleev left room for elements that had not yet been discovered.

APPLY CONCEPTS Emphasize that Mendeleev did not make the first periodic table, but he did make the first table that gained wide acceptance. Explain that these tables were true periodic tables since they arranged the elements according to periodicity of their chemical and physical properties. Bring awareness to the fact that protons are used to define elements, but at the point in time when these tables were created, the proton had yet to be discovered.

Answers

FIGURE 6.2 F

Explain

Today's Periodic Table

USE VISUALS Direct students' attention to Figure 6.3. This is the first of three periodic tables in the chapter. The information in this first table is limited so that students can see how all the elements fit in the table and can focus on atomic number as an organizing principle.

Have students compare Figures 6.2 and 6.3. **Ask** How is the modern periodic table shown here similar to Mendeleev's periodic table? *(In both tables, elements are arranged in rows and columns. Mendeleev's periodic table ordered the elements according to atomic mass. Modern periodic tables order elements according to atomic number.)* **Ask** What does an element's position in the table indicate about its properties? *(The properties of an element are similar to those of other elements in the same group.)*

INTERPRET DIAGRAMS Display Figure 6.3 on an overhead. To emphasize the concept that elements in the same group, or column, of the periodic table have similar properties, isolate one group with two sheets of paper. Describe some physical and chemical properties of the elements in that group. Then, point to the group on the far right, and explain that all of these elements are gases that do not normally form compounds. Have students compare these elements to those in other groups.

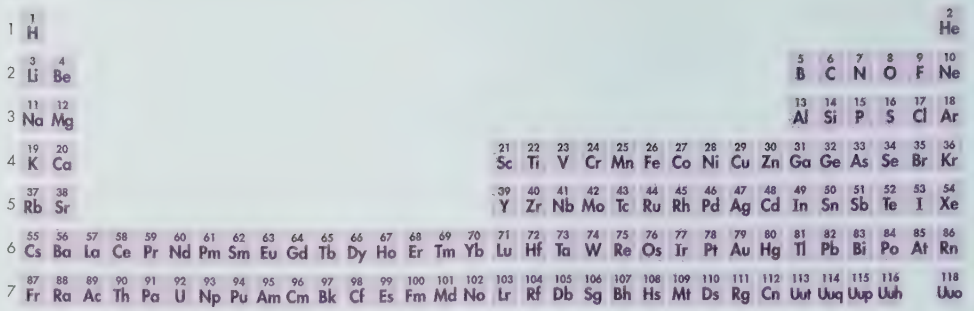

Figure 6.3 Modern Periodic Table
In the modern periodic table, the elements are arranged in order of increasing atomic number.
Interpret Diagrams *How many elements are in the second period?*

Today's Periodic Table

How is the modern periodic table organized?

The atomic mass of iodine (I) is 126.90. The atomic mass of tellurium (Te) is 127.60. In a periodic table based on atomic mass, iodine should come before tellurium since iodine has a smaller atomic mass than tellurium does. However, based on its chemical properties, iodine belongs in a group with bromine and chlorine. Mendeleev broke his rule about placing elements in strict order of atomic mass and placed tellurium before iodine in his periodic table. He assumed that the atomic masses for iodine and tellurium were incorrect, but they were not. A similar problem occurred with other pairs of elements. The problem wasn't with the atomic masses but with using atomic mass to organize the periodic table.

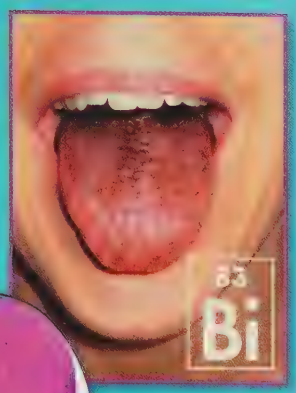
Mendeleev developed his table before scientists knew about the structure of atoms. He didn't know that the atoms of each element contain a unique number of protons. Recall that the number of protons is the atomic number. In 1913, a British physicist, Henry Moseley, determined an atomic number for each known element. Tellurium's atomic number is 52 and iodine's is 53, so it makes sense for iodine to come after tellurium in the periodic table. **In the modern periodic table, elements are arranged in order of increasing atomic number.**

The elements in Figure 6.3 are arranged in order of atomic number, starting with hydrogen, which has atomic number 1. There are seven rows, or periods, in the table. Period 1 has 2 elements, Period 2 has 8 elements, Period 4 has 18 elements, and Period 6 has 32 elements. Each period corresponds to a principal energy level. There are more elements in higher numbered periods because there are more orbitals in higher energy levels. (Recall the rules you studied in Chapter 5 for how electrons fill orbitals.)

The properties of the elements within a period change as you move across a period from left to right. However, the pattern of properties within a period repeats as you move from one period to the next. This pattern gives rise to the **periodic law:** When elements are arranged in order of increasing atomic number, there is a periodic repetition of their physical and chemical properties. The arrangement of the elements into periods has an important consequence. Elements that have similar chemical and physical properties end up in the same column in the periodic table.

READING SUPPORT
Build Vocabulary: ***Word Origins***
Periodic comes from the Greek roots *peri,* meaning "around" and *hodos,* meaning "path." In a periodic table, properties repeat from left to right across each period. ***If the Greek word* metron *means "measure," what does* perimeter *mean?***

Differentiated Instruction



LPR LESS PROFICIENT READERS Using a large poster-size display of the periodic table, trace one period across the table. On the display, note some physical and chemical properties of each element in that period. Then have students research the properties of each element in the period below the one you just highlighted and write a comparison statement comparing the properties of both periods.

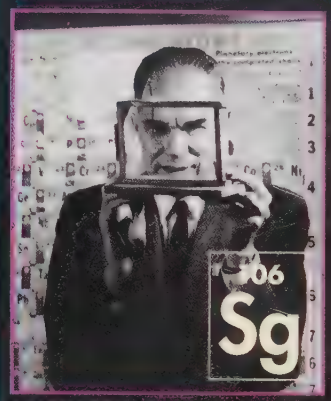
ELL ENGLISH LANGUAGE LEARNERS To help students understand the term "group" on the periodic table, assign the term the down-arrow symbol. Convey that a *group* of elements means the same as a *column* of elements. To help students understand the term "period" on the periodic table, assign the term the right-arrow symbol. Convey that a *period* of elements means the same as a *row* of elements. Other words such as *vertical* and *horizontal* can also be used in place of *group* and *period.*

L3 STRUGGLING STUDENTS Review Lesson 4.3 to help students understand how the atomic numbers and the atomic mass of elements are important to the modern periodic table.

"Elemental" Trivia

Did you know that the stench of a skunk's spray is largely due to compounds that contain the element sulfur, or that rubies are red because of small amounts of chromium? Discover more fun facts about other elements as you read this page.

BISMUTH A compound containing bismuth is commonly used to treat indigestion. The bismuth in the medicine binds with sulfur-containing compounds produced by bacteria in the mouth.



MAGNESIUM Magnesium is a component of chlorophyll, the green pigment in plants that enables photosynthesis to occur.

12
Mg

ANTIMONY The element antimony is often used to increase the hardness and strength of pewter figurines.

SEABORGIUM In 1974, this element was created by a team of scientists that included Glenn T. Seaborg. It was the first element to be named after a living person.

1
H

HYDROGEN Hydrogen is the most abundant element in the universe and, along with other gases, is found in the sun and stars.

Take It Further

1. Explain In elemental form, antimony (Sb) and bismuth (Bi) are both brittle, crystalline solids at room temperature. They are also poor conductors of heat and electricity. How does the periodic law support this observation? Use Figure 6.3 to explain your answer.

2. Classify Look ahead to Figure 6.4. Use the figure to classify the five elements above as metals, nonmetals, or metalloids.

21st Century Learning The following project involves the following 21st Century Skills: *Creativity and Innovation, Communication and Collaboration, Information Literacy, Media Literacy, Flexibility and Adaptability, Initiative and Self-Direction, Social and Cross-Cultural Skills, Productivity* and *Accountability, and Leadership and Responsibility.*

ELEMENT GAME Pose the following challenge to students. *You have been hired to create an educational game. Form a team of 3–5 people to create a new board game to teach facts about the elements.*

- Research and make a list of at least 30 element fun facts. Be sure each fact is something interesting. Keep a copy of source materials for each fact.
- Create a board game that can be used to learn about chemical elements. Be sure the design is engaging, creative, and durable. Design and create all the parts for the game, and build a prototype.
- Test your game by having other groups play it, and then complete a survey about the game. Redesign the game as needed based on feedback.

CHEMISTRY & YOU Lead students in discussing the photos and reading aloud the trivia facts about the elements. Encourage students to describe ways that these elements affect their everyday lives. Point out that some elements have interesting stories behind their names. In some cases, a name is derived from Greek or Latin words early scientists felt were representative of the element. Some elements have interesting facts about their uses or their discoveries. Note that the International Union for Pure and Applied Chemistry (IUPAC) now requires elements to be named after a concept in mythology, a person, a place or country, a mineral, a property, or a scientist.

Have students examine the periodic table. Pose the following challenge to students: *How many elements can you find that are named after places? People? Greek or Latin words? Properties? Minerals?* Provide students with the following examples to get them started:

- Places: californium, after the state
- People: copernicum, after Copernicus
- Mineral: beryllium, after a gemstone
- Property: chlorine, for its color
- Scientist: seaborgium, after one of its discoverers
- Mythological concept: thorium, after the Scandinavian god of war

Extend

Connect to ASTRONOMY

Have students look at the periodic table and identify the four elements named after planets.

- Mercury was named after the planet Mercury, but its symbol, Hg, is derived from the Greek word *hydrargyros,* meaning "liquid silver."
- Uranium is named after the planet Uranus.
- Plutonium is named after the dwarf planet Pluto.
- Neptunium is named after the planet Neptune.

Answers

FIGURE 6.3 8

READING SUPPORT One meaning of *perimeter* is "a line or boundary around an area." It comes from *peri-*, "around," and *meter*, "measure."

TAKE IT FURTHER

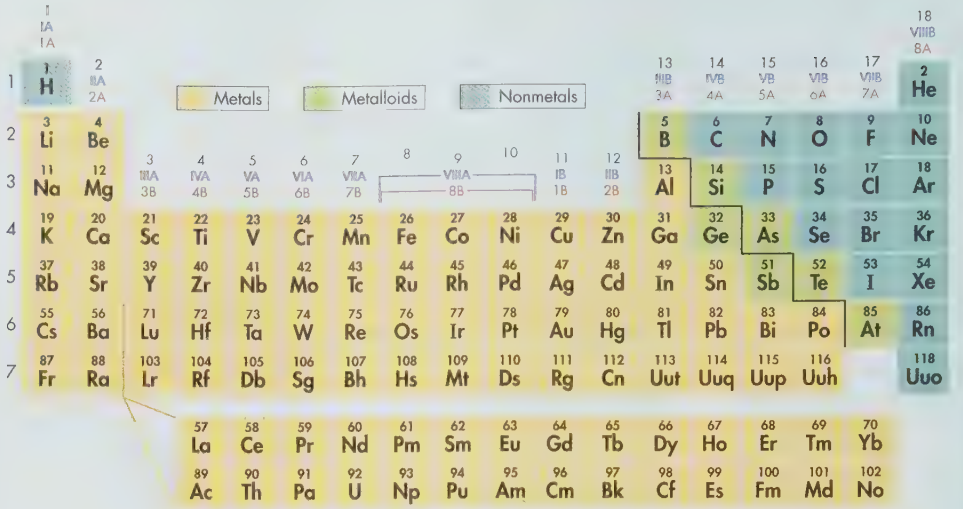
1. Antimony and bismuth are in the same column in the periodic table.
2. metals: bismuth, magnesium, and seaborgium; nonmetal: hydrogen; metalloid: antimony

Explain

Metals, Nonmetals, and Metalloids

USE VISUALS Have students examine Figure 6.4. Explain the color key and use the color coding to help identify the sections of the table that correspond to metals, nonmetals, and metalloids. Emphasize the periodic trend across each period from metals to nonmetals. **Ask** Which class of elements do most of the elements belong to? *(metals)* **Ask** What do the three numbers at the top of each column represent? *(different systems for numbering the groups)* Explain that the numbers in blue were used initially, but over time the International Union for Pure and Applied Chemistry changed to the red numbers. The most recent change, to the black system, eliminated the use of A and B subgroups and established a 1 to 18 numbering system. Note that both red and black systems are in use today, but that the system shown in blue is no longer used.

USE AN ANALOGY Use a monthly calendar to show students how the concepts of a monthly calendar are similar in theory to that of the periodic table: The same progression of days occurs each week. Then explain how the calendar and periodic table differ: Although the length of a day is based on a natural event (Earth's rotation), what happens on a Monday or Saturday depends on human decisions, not on an underlying natural principle.



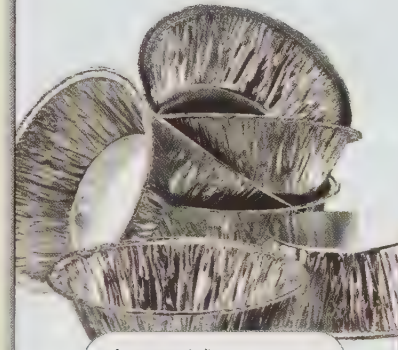


Figure 6.4 Classifying Elements
Periodic tables are sometimes color-coded to classify certain types of elements. This periodic table classifies elements as metals (yellow), nonmetals (blue), and metalloids (green).

Figure 6.5 Metals
The metals aluminum, copper, and iron have many important uses. The properties of the metal determine how it is used.

Aluminum (Al)
Aluminum is one of the metals that can be shaped into a thin sheet, or foil.

Copper (Cu)
Copper is ductile and second only to silver as a conductor of electric current. The copper used in electrical cables must be 99.99 percent pure.

Metals, Nonmetals, and Metalloids

What are three broad classes of elements?

Most periodic tables are laid out like the one in Figure 6.4. Notice some elements from Periods 6 and 7 are placed beneath the table. This arrangement makes the periodic table more compact. It also reflects an underlying structure of the periodic table, which you will study in Lesson 6.2. Each column, or group, in this table has three labels. Scientists in the United States primarily use the labels shown in red. Scientists in Europe use the labels shown in blue.

For scientists to communicate clearly, they need to agree on the standards they will use. The International Union of Pure and Applied Chemistry (IUPAC) is an organization that sets standards for chemistry. In 1985, IUPAC proposed a new system for labeling groups in the periodic table. They numbered the groups from left to right 1 through 18 (the black labels in Figure 6.4). The large periodic table in Figure 6.9 includes the IUPAC system and the system used in the United States.

Dividing the elements into groups is not the only way to classify them based on their properties. The elements can be grouped into three broad classes based on their general properties. **Three classes of elements are metals, nonmetals, and metalloids.** Across a period, the properties of elements become less metallic and more nonmetallic.

UbD Check for Understanding

How is the modern periodic table organized?

Assess students' understanding of the organization of the periodic table by having them write a one-minute explanation of how the periodic table of elements used today is organized. Explanations should describe the main reason and/or benefit for this organizational structure. *(Today's periodic table is organized by atomic number. This allows for an easier understanding of an element's properties due to the patterns and trends in the groups and periods.)*

ADJUST INSTRUCTION If students are struggling in their responses, direct them to read the text following the lesson on Today's Periodic Table and to create a table of facts. Then, allow students to use their tables to revise their explanations.

Metals The number of yellow squares in Figure 6.4 shows that most elements are metals—about 80 percent. **Metals** are generally good conductors of heat and electric current. A freshly cleaned or cut surface of a metal will have a high luster, or sheen. The sheen is caused by the metal's ability to reflect light. All metals are solids at room temperature, except for mercury (Hg). Many metals are ductile, meaning that they can be drawn into wires. Most metals are malleable, meaning that they can be hammered into thin sheets without breaking. Figure 6.5 shows how the properties of metals can determine how metals are used.

Nonmetals In Figure 6.4, blue is used to identify the nonmetals. With the exception of hydrogen, these elements are in the upper-right corner of the periodic table. There is a greater variation in physical properties among nonmetals than among metals. Most nonmetals are gases at room temperature, including the main components of air—nitrogen and oxygen. A few are solids, such as sulfur and phosphorus. One nonmetal, bromine, is a dark-red liquid. Some examples of nonmetals are shown in Figure 6.6.

The variation among nonmetals makes it difficult to describe one set of general properties that will apply to all nonmetals. However, nonmetals tend to have properties that are opposite to those of metals. In general, **nonmetals** are poor conductors of heat and electric current. Carbon, in the form of graphite, is an exception to this rule. Solid nonmetals tend to be brittle, meaning that they will shatter if hit with a hammer.

Figure 6.6 Nonmetals
The properties of nonmetals vary.

Carbon (C) and Phosphorus (P)
A diamond, which is composed of carbon, is very hard. Some match heads are coated with phosphorus, a brittle solid.

Iron (Fe)
Cloud Gate in Chicago, Illinois, is covered in stainless steel, which contains iron and chromium (Cr). The steel is shiny, malleable, and strong. It also resists rusting.

Test properties of metals *online.*

Differentiated Instruction

LPR LESS PROFICIENT READERS Make a chart on the board of the three types of elements. Have students complete the chart by adding details about the general characteristics of each type of element. As a class, compare and contrast metals, nonmetals, and metalloids.

L1 SPECIAL NEEDS STUDENTS Provide a large periodic table mat and colored chips or blocks to use as markers. Have students place a marker(s) on the element(s) that is being discussed. Allow students to use these tactile objects during assessments.

L3 ADVANCED STUDENTS Have students research semiconductors; students should define the term and note where the elements that are used for the application are located in the periodic table.

Explore

Class Activity

Have each student choose an element without revealing the choice to other students. Each student should write a short description of the chosen element to read to the class. Ask the other students to identify the element from the description. Encourage students to be as specific as possible in their descriptions. Example: bromine is a reddish-brown liquid.

Extend

Connect to METALLURGY

Aluminum has the best strength-to-weight ratio of any commonly used metal, and it weighs about one-third less than steel. Have students determine four other properties of aluminum that make it a better option to use in a product than other commonly used metals. *(Properties of aluminum: low density, relatively high strength, corrosion resistant even without surface protection, nonstaining, high conductivity, nonmagnetic, etc.)*

Explain

CHEMISTRY & YOU You could use the periodic table to classify the elements according to physical state (solid, liquid, gas) or whether or not they are found in nature.

CRITICAL THINKING Point out silicon's position in the periodic table and explain that silicon is a metalloid, an element having both metallic and nonmetallic properties. **Ask** In terms of conductance, how can you distinguish metals from nonmetals? *(Metals are good conductors of heat and electricity, and nonmetals are poor conductors of heat and electricity.)* **Ask** Name other elements that are classified as metalloids. *(Chemists do not always agree on which elements to classify as metalloids. Some include polonium (Po) and astatine (At) as metalloids. Some classify polonium as a metal and astatine as a nonmetal.)*

Evaluate

Informal Assessment

Have students explain how Mendeleev contributed to the development of today's periodic table. **Ask** Why did Mendeleev leave gaps in his periodic table? *(He predicted that more elements would one day be discovered, and he was correct.)* **Ask** What do elements in the same group have in common? *(the principle energy level)* Have students name a metal, a metalloid, and a nonmetal using the name and symbol of the element. *(Answers will vary.)* Then have students complete the 6.1 Lesson Check.

Reteach

Direct students' attention to Figure 6.2 and provide them with a printout of the modern table. Remind students that Mendeleev's rows are the equivalent of the modern groups, so students may wish to rotate their periodic table to correspond to Mendeleev's table. Point out that Mendeleev's practice of classification on the basis of increasing atomic mass had its problems. Have students locate thallium (Tl) and nickel (Ni) in both tables and compare their placement in each table. Point out that when classified on the basis of atomic mass, Tl is grouped with the alkali metals, even though its properties are much less metallic than those of other elements in Group 1A. Note that Ni overlaps with cobalt (Co) in Mendeleev's table because at that time, their atomic masses were thought to be equal. By organizing on the basis of atomic numbers, the modern table avoids these types of problems.

CHEMISTRY & YOU

Q: *All of the known elements are listed in the periodic table. What are different ways you could use the periodic table to classify elements?*

Metalloids There is a heavy stair-step line in Figure 6.4 that separates the metals from the nonmetals. Most of the elements that border this line are shaded green. These elements are metalloids. A **metalloid** generally has properties that are similar to those of metals and nonmetals. Under some conditions, a metalloid may behave like a metal. Under other conditions, it may behave like a nonmetal. The behavior often can be controlled by changing the conditions. For example, like most nonmetals, pure silicon is a poor conductor of electric current. However, if a small amount of boron is mixed with silicon, the mixture is a good conductor of electric current. Silicon can be cut into wafers and used to make computer chips. Silicon is also present as the compound silicon dioxide in glass items like the one in Figure 6.7.

Figure 6.7 Metalloid Computer chips and glass are two common items than contain metalloids.

ONLINE PROBLEMS

6.1 LessonCheck

1. **Explain** How did chemists begin the process of organizing elements?
2. **Identify** What property did Mendeleev use to organize his periodic table?
3. **Explain** How are elements arranged in the modern periodic table?
4. **List** Name the three broad classes of elements.
5. **Classify** Identify each element as a metal, a metalloid, or a nonmetal.
   - **a.** gold
   - **b.** silicon
   - **c.** sulfur
   - **d.** barium
6. **Compare** Which of the following sets of elements have similar physical and chemical properties?
   - **a.** oxygen, nitrogen, carbon, boron
   - **b.** strontium, magnesium, calcium, beryllium
   - **c.** nitrogen, neon, nickel, niobium
7. **Identify** Name two elements that have properties similar to those of the element sodium.

BIGIDEA
ELECTRONS AND THE STRUCTURE OF ATOMS

8. Why is atomic number better than atomic mass for organizing the elements in the periodic table?

Lesson Check Answers

1. Chemists used the properties of elements to sort them into groups.
2. atomic mass
3. in order of increasing atomic number
4. metals, metalloids, nonmetals
5. **a.** metal **b.** metalloid **c.** nonmetal **d.** metal
6. b
7. lithium, potassium, rubidium, cesium, or francium
8. **BIG**IDEA It is a good way to organize elements because atomic number is unique for each element, while other properties, such as atomic mass, can vary for atoms of an element.

6.2 Classifying the Elements

C.2.5 Write an element's electron configuration; C.2.6 Determine valence electrons and properties

CHEMISTRY & YOU

Q: *What can you learn about each element from the periodic table?*

Many people carry a form of identification, such as a driver's license. An ID contains information specific to a particular person, such as the person's name, address, height, eye color, and weight. The periodic table contains a square for each element that supplies information about that element. In this lesson, you will learn the types of information that are usually listed in a periodic table.

Key Questions

What information can be displayed in a periodic table?

How can elements be classified based on electron configurations?

Vocabulary

- alkali metal
- alkaline earth metal
- halogen
- noble gas
- representative element
- transition metal
- inner transition metal

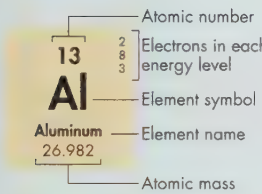

Figure 6.8 Periodic Table Square
This is the element square for aluminum from the periodic table in Figure 6.9.
Interpret Diagrams *What does the data in the square tell you about the structure of an aluminum atom?*

Reading the Periodic Table

What information can be displayed in a periodic table?

The periodic table is a very useful tool in chemistry. **The periodic table usually displays the symbols and names of the elements, along with information about the structure of their atoms.** Figure 6.8 shows one square from the detailed periodic table of the elements in Figure 6.9 on page 168. In the center of the square is the symbol for aluminum (Al). The atomic number for aluminum (13) is above the symbol. The element name and atomic mass are below the symbol. There is also a vertical column with the numbers 2, 8, and 3, which indicate the number of electrons in each occupied energy level of an aluminum atom.

The symbol for aluminum is printed in black because aluminum is a solid at room temperature. In Figure 6.9, the symbols for gases are in red. The symbols for the two elements that are liquids at room temperature, mercury and bromine, are in blue. The symbols for some elements in Figure 6.9 are printed in grey. These elements are not found in nature. In Chapter 25, you will learn how scientists produce these elements.

The background colors in the squares are used to distinguish groups of elements in the periodic table. For example, two shades of orange are used for the metals in Groups 1A and 2A. The elements in Group 1A are called **alkali metals.** The elements in Group 2A are called **alkaline earth metals.** The name alkali comes from the Arabic *al aqali,* meaning "the ashes." Wood ashes are rich in compounds of the alkali metals sodium and potassium. Some groups of nonmetals also have special names. The nonmetals of Group 7A are called **halogens.** The name *halogen* comes from the combination of the Greek word *hals,* meaning "salt," and the Latin word *genesis,* meaning "to be born." There is a general class of compounds called salts, which include the compound called table salt. Chlorine, bromine, and iodine, the most common halogens, can be prepared from their salts.

Focus on ELL

1 CONTENT AND LANGUAGE Use a deck of cards to clarify the difference between the words *organize* and *classify.* Show how they can classify the cards into suits or colors, but that organizing the cards is different.

2 FRONTLOAD THE LESSON Display pictures of coins from various countries and in different denominations. Be sure that the images show both sides of each coin. Ask students to list the types of information found on each coin and consider how that information can be used to identify each coin. Tells students that the squares of the periodic table also contain several important pieces of information that can be used to identify each element.

3 COMPREHENSIBLE INPUT When discussing Figure 6.13, project the figure on the board. Refer students back to the electron configurations for the elements in Groups 1A–8A, and then fill in these elements in their appropriate blocks on the figure to reinforce the relationship between electron configuration and element groups.

Key Objectives

6.2.1 DESCRIBE the information in a periodic table.

6.2.2 CLASSIFY elements based on electron configuration.

Additional Resources

Reading and Study Workbook, Lesson 6.2

Available Online or on Digital Media:

- Teaching Resources, Lesson 6.2 Review
- Laboratory Manual, Lab 9

PearsonChem.com

Engage

CHEMISTRY & YOU After students read the opening paragraph, have them brainstorm other examples of small items that contain lots of information (e.g., coins, train schedules, digital watch face, and nutrient labels). As a class, discuss the information that each of these items provide.

Access Prior Knowledge

Have students review what they learned about atomic numbers, atomic mass, and chemical symbols in Chapter 4. Then, review what they learned about the periodic table in the previous lesson, and determine how this information relates to the information from Chapter 4.

IN ACADEMIC STANDARDS for SCIENCE

C.2.5 Write the electron configuration of an element and relate this to its position on the periodic table.

C.2.6 Use the periodic table and electron configurations to determine an element's number of valence electrons and chemical and physical properties.

Answers

FIGURE 6.8 There are 13 protons in the nucleus and 13 electrons in the three occupied energy levels.

Foundations for Reading

BUILD VOCABULARY Have students use the LINCS strategy. In LINCS exercises, students **L**ist what they know about each term, **I**magine a picture that describes the term, **N**ote a reminding "sound-alike" word, **C**onnect the terms to the sound-alike word by making up a short story, and then perform a brief **S**elf-test.

READING STRATEGY After students preview the lesson, have them predict the relationship between an element's electron configuration and its position in the periodic table. Students can revise their predictions after they read the lesson.

Explain

Reading the Periodic Table

USE VISUALS Have students examine Figure 6.8 on the previous page. Remind students what atomic mass represents. Make sure that students understand what the vertical column of numbers on the right-hand side of each block represents. Refer students back to the discussion of electron configuration in Chapter 5 for review, if needed.

Make sure students understand that each column in the table is a group, and at the top of each column is a number that indicates the group number. **Ask** What elements are in Group 4B? *(Ti, Zr, Hf, Rf)*

USE VISUALS Have students examine the periodic table in Figure 6.9. Discuss as a class the information that can extracted from the table. **Ask** Why is the symbol for bromine and mercury displayed in blue ink? *(They are liquids.)* **Ask** What series of elements come between Groups 2A and 3A in the periodic table? *(the lanthanide and actinide elements)*

SUMMARIZE Have students write summary statements for the information that can or cannot be extracted from the periodic table for the following: element name, atomic number, atomic mass, and physical state at atmospheric pressure and room temperature.

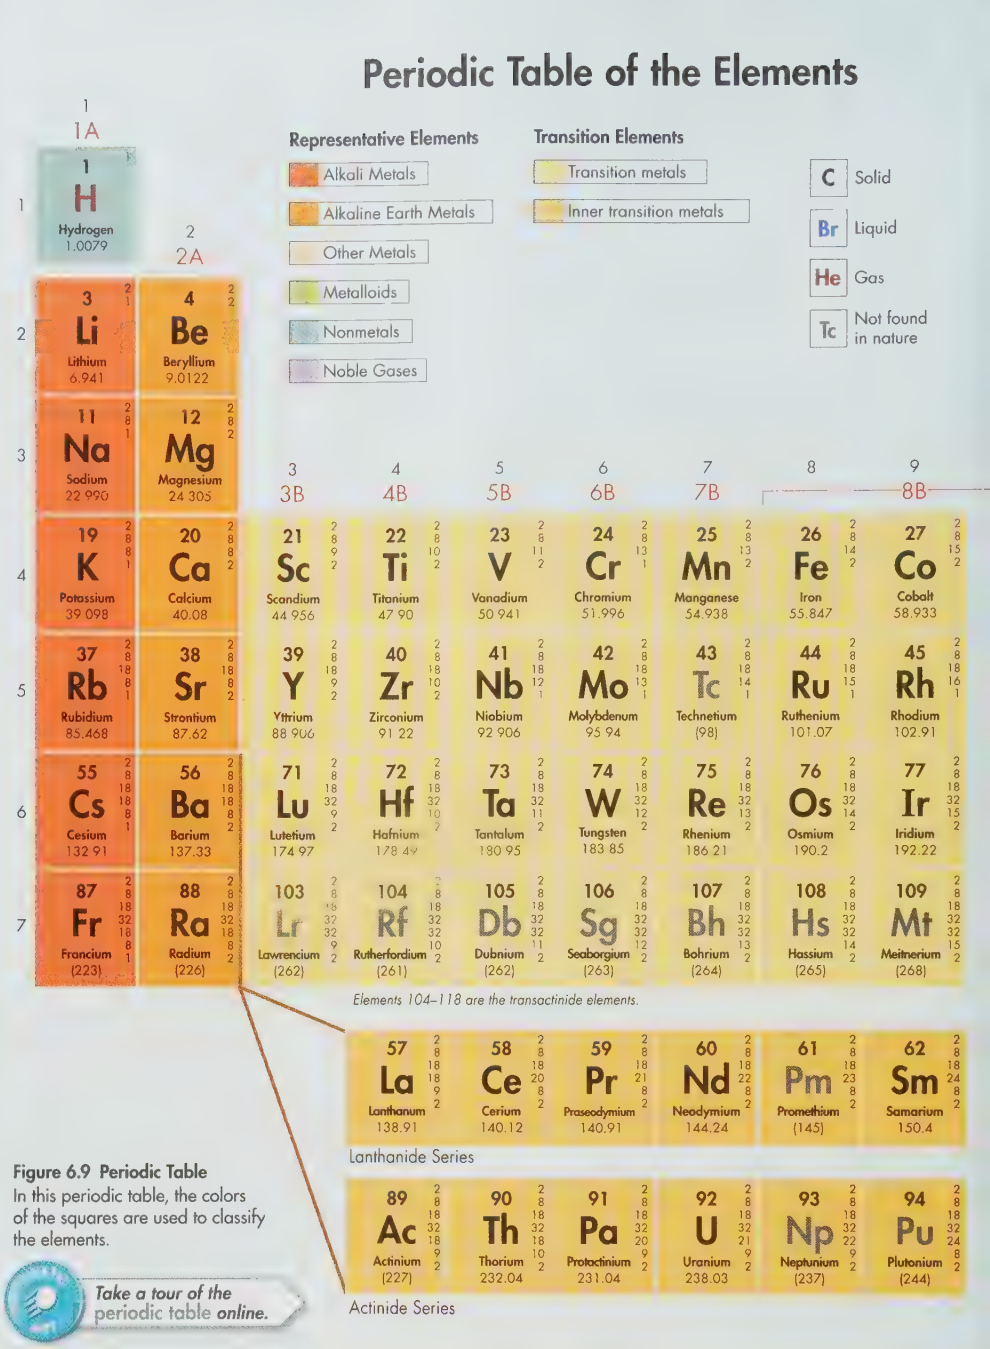

Figure 6.9 Periodic Table
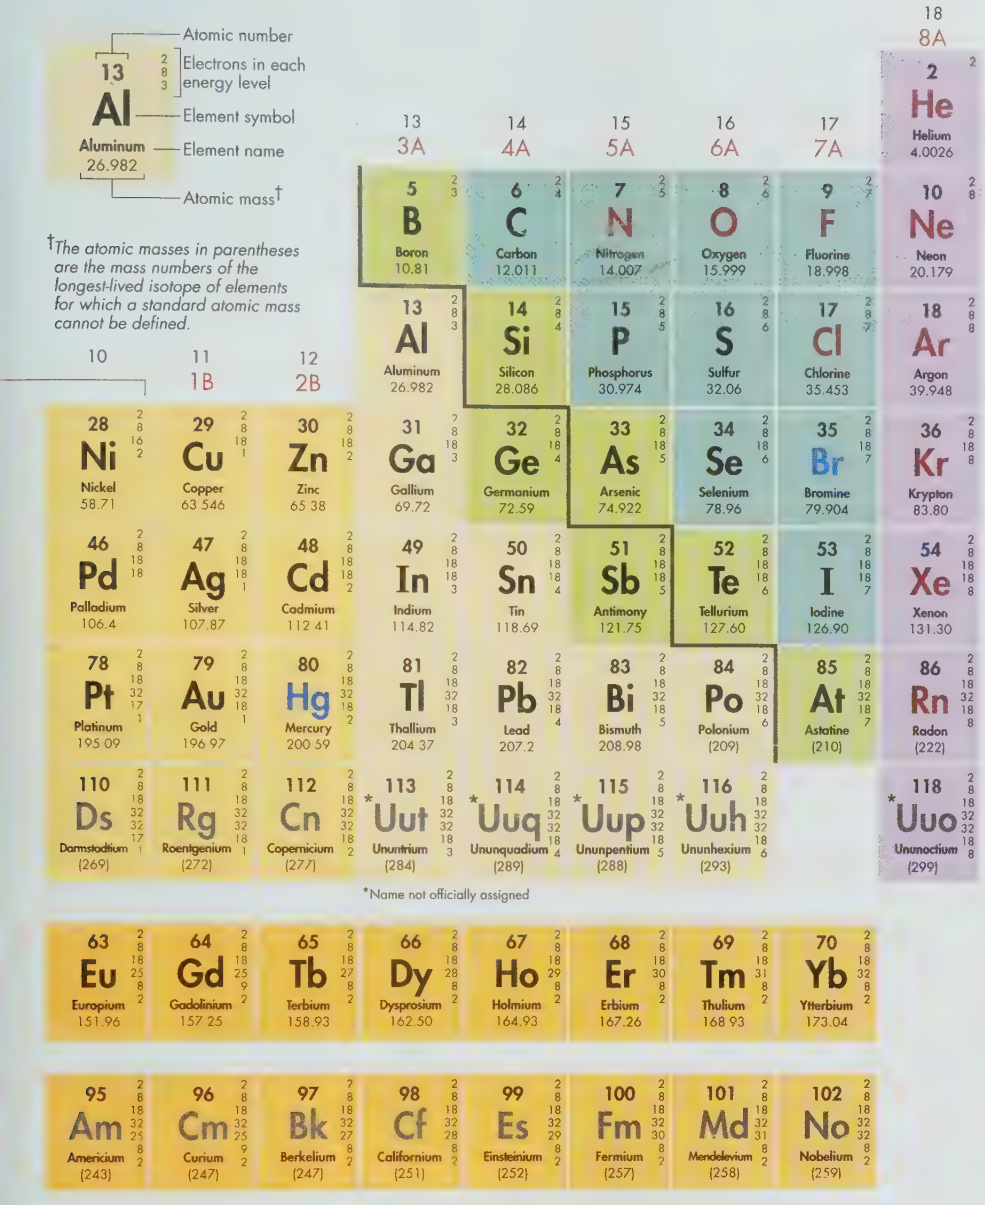
In this periodic table, the colors of the squares are used to classify the elements.



Take a tour of the periodic table online.

Professional Development Note

Element Nomenclature

Names suggested by those who discover new elements must be approved by the International Union of Pure and Applied Chemistry (IUPAC). The process can be lengthy. For example, the names chosen for elements 104–108 by the nomenclature committee of IUPAC in 1994 were not those endorsed by the American Chemical Society (ACS). After years of negotiation, a compromise resulted in the names that appear in the periodic table.

The most recent element to be officially named is copernicum (Cn), atomic number = 112. Copernicum was discovered in 1996 in the same lab in Darmstadt, Germany that was responsible for discovering several other new elements. The IUPAC Council voted formal approval of the name *copernicum* on February 19, 2010. The element is named for the scientist Nicolaus Copernicus, known for his development of a model explaining movements within the solar system.

Differentiated Instruction

LPR LESS PROFICIENT READERS Explain that reading a table involves reading the title first, followed by reading the key, and then by examining the data presented in the table. Review each aspect of the color key used in the periodic table.

L1 SPECIAL NEEDS STUDENTS Have students use an online annotated periodic table. Students can click on an element to see or hear information and properties about the element.

L3 ADVANCED STUDENTS Mendeleev predicted that certain elements that were missing from his table would have specific properties. Have students research Mendeleev's predictions for ekaaluminum (gallium), ekaboron (scandium), and ekasilicon (germanium) and compare them to the known properties of each element. Have students create a table demonstrating the similarities and differences between Mendeleev's predictions and what we now know about each element's properties.

DRAW CONCLUSIONS Have students examine the periodic table and determine the accuracy of this statement: Atomic mass always increases as atomic number increases. *(The trend is generally true, but there are exceptions. For example, the atomic numbers of Co, Ni, and Cu increase by one unit (27, 28, 29), but Ni has the lowest average atomic mass of these three elements.)*

Extend

CHEMISTRY & YOU From the periodic table, you can learn several things about a particular element—whether the element is a solid, liquid, or gas at room temperature; how many electrons, protons, and neutrons it has; its atomic mass; whether it is a metal, metalloid, or nonmetal; its electron configuration; and its name and symbol.

Connect to PHYSIOLOGY

Have students start a list of elements found in the human body that are essential for metabolism. Explain that many elements are present in trace amounts but are, nevertheless, essential for survival. Have students research elements such as copper, chromium, iodine, and manganese to find out more about their biological roles. Encourage students to begin their investigation with micronutrients.

Explain

Electron Configurations in Groups

APPLY CONCEPTS Lead a class discussion on electron configurations of noble gases and representative elements. Select some elements and have students write out the electron configurations for those elements. Have students compare the electron configurations for all the elements in a single group. Ask students to identify similarities. *(Noble gases are sometimes classified as representative elements because they are in the* p *block of elements.)*

CHEMISTRY & YOU

Q: *What can you learn about each element from the periodic table?*

Electron Configurations in Groups

How can elements be classified based on electron configurations?

Electrons play a key role in determining the properties of elements, so there should be a connection between an element's electron configuration and its location in the periodic table. **Elements can be sorted into noble gases, representative elements, transition metals, or inner transition metals based on their electron configurations.** You may want to refer to the periodic table as you read about these classes of elements.

The Noble Gases The photos in Figure 6.10 show uses of helium, neon, and argon. Helium, neon, and argon are examples of **noble gases,** the elements in Group 8A of the periodic table. These nonmetals are sometimes called the inert gases because they rarely take part in a reaction. The electron configurations for the first four noble gases in Group 8A are listed below.

Helium (He)	$1s^2$
Neon (Ne)	$1s^2 2s^2 2p^6$
Argon (Ar)	$1s^2 2s^2 2p^6 3s^2 3p^6$
Krypton (Kr)	$1s^2 2s^2 2p^6 3s^2 3p^6 3d^{10} 4s^2 4p^6$

Look at the description of the highest occupied energy level for each element, which is highlighted in yellow. The *s* and *p* sublevels are completely filled with electrons—two electrons in the *s* sublevel and six electrons in the *p* sublevel. Chapter 7 will explain how this arrangement of electrons is related to the relative inactivity of the noble gases.

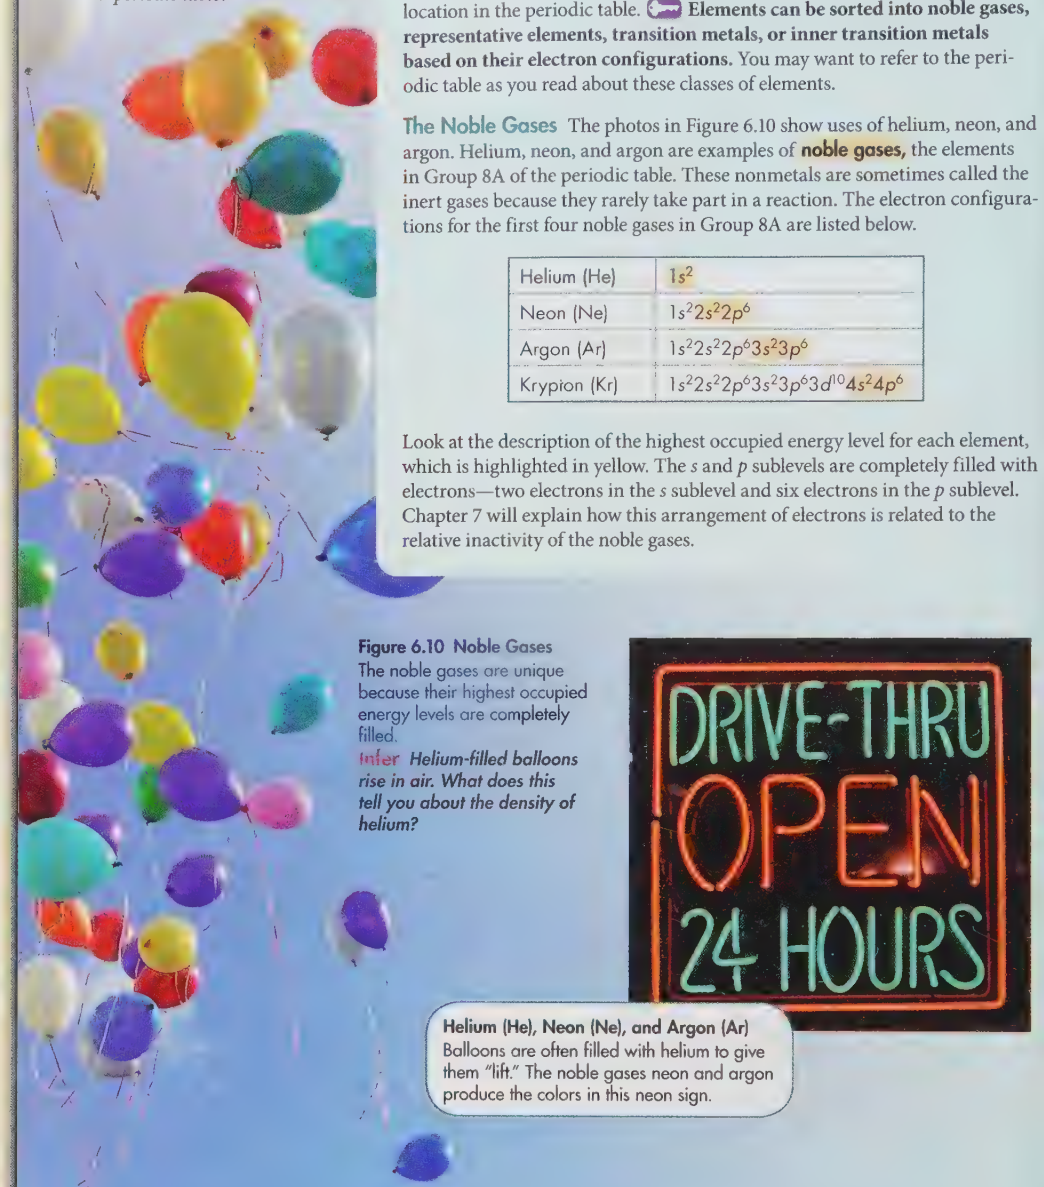


Figure 6.10 Noble Gases
The noble gases are unique because their highest occupied energy levels are completely filled.
Infer ***Helium-filled balloons rise in air. What does this tell you about the density of helium?***

Helium (He), Neon (Ne), and Argon (Ar) Balloons are often filled with helium to give them "lift." The noble gases neon and argon produce the colors in this neon sign.

UbD Check for Understanding

The Essential Question **What information does the periodic table provide?**

Assess students' knowledge about the periodic table by having students use a thumbs-up sign to indicate if the information listed in each statement below can be found in the periodic table, and a thumbs-down sign if it cannot be found there.

- The date an element was discovered *(no)*
- An element with properties similar to neon *(yes)*
- The boiling point of magnesium *(no)*
- The atomic mass of nitrogen *(yes)*
- An element that is a good conductor of heat *(yes)*

ADJUST INSTRUCTION If students are having trouble answering, have them re-examine Figures 6.8 and 6.9. Call out an element and have students write down all of the information about the element and what the information is based on.

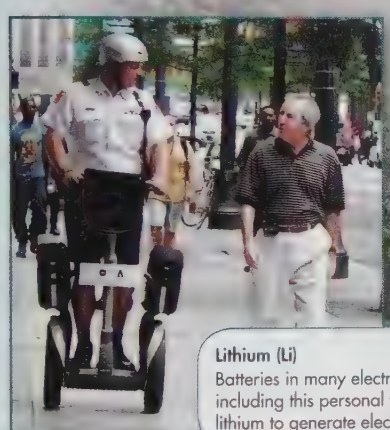
The Representative Elements Figure 6.11 shows the portion of the periodic table containing Groups 1A through 7A. Elements in Groups 1A through 7A are often referred to as **representative elements** because they display a wide range of physical and chemical properties. Some elements in these groups are metals, some are nonmetals, and some are metalloids. Most of them are solids, but a few are gases at room temperature, and one, bromine, is a liquid.

In atoms of representative elements, the *s* and *p* sublevels of the highest occupied energy level are not filled. Look at the electron configurations for lithium, sodium, and potassium below. In atoms of these Group 1A elements, there is only one electron in the highest occupied energy level. The electron is in an *s* sublevel.

Lithium (Li)	$1s^2 2s^1$
Sodium (Na)	$1s^2 2s^2 2p^6 3s^1$
Potassium (K)	$1s^2 2s^2 2p^6 3s^2 3p^6 4s^1$

In atoms of the Group 4A elements carbon, silicon, and germanium, there are four electrons in the highest occupied energy level.

Carbon (C)	$1s^2 2s^2 2p^2$
Silicon (Si)	$1s^2 2s^2 2p^6 3s^2 3p^2$
Germanium (Ge)	$1s^2 2s^2 2p^6 3s^2 3p^6 3d^{10} 4s^2 4p^2$



For any representative element, its group number equals the number of electrons in the highest occupied energy level.

Figure 6.11 Representative Elements Some of the representative elements exist in nature as elements. Others are found only in compounds.

Tin (Sn)
Artisans often coat objects made of other metals with tin because tin resists corrosion.

Lithium (Li)
Batteries in many electronic devices, including this personal vehicle, use lithium to generate electrical energy.

Sulfur (S)
Some volcanos release high amounts of sulfur vapors. The sulfur cools and is deposited as a solid yellow powder.

Differentiated Instruction

L1 STRUGGLING STUDENTS Divide the class into small groups. Have each group write electron configurations for an *s*-block element, a *p*-block element, a *d*-block element, and an *f*-block element. Avoid assigning any of the *d*-block elements with unpredictable configurations. Ask students to explain the method they used to determine specific electron configurations.

LPR LESS PROFICIENT READERS Prior to the teacher demo, have students place markers on the elements magnesium, tin, copper, and hydrogen on their periodic table. Discussing one element at a time, explain what is needed in regard to gaining or losing an electron in order to achieve the nearest noble gas electron configuration. Have students predict which element is most likely to react and which element is least likely to react with HCl. Discuss the predictions after the demonstration.

L3 ADVANCED STUDENTS Have students write an expression for the pattern they notice in the outer shell electron configuration for the noble gases. (ns^2np^6, *where n = the number of the period, n >1)*

Explain

USE VISUALS Direct students' attention to Figure 6.11. **Ask** What pattern do you notice in the electron configuration for Group 1A elements? *(The s-level is not completely filled.)* **Ask** Predict the pattern for the electron configuration for Group 2A elements. *(Answers will vary.)*

Explore

Teacher Demo

PURPOSE Students observe differences in the reactivity of magnesium, tin, and copper.

MATERIALS 0.2*M* HCl; 6 large test tubes; test tube rack; small pieces of clean magnesium, tin, or copper; matches; wood splint

SAFETY Wear goggles for this demo.

PROCEDURE Place three large test tubes in a test tube rack. To each test tube, add a small, clean piece of a different metal—magnesium, tin, or copper. Carefully add some of the 0.2*M* HCl to each test tube and invert another test tube over it. Point out the appearance of bubbles. After a while, carefully ignite the hydrogen in the inverted test tube from the magnesium or tin reaction.

EXPECTED OUTCOME The magnesium and tin react with the HCl, producing hydrogen. The hydrogen ignites with an explosive pop. The copper shows no sign of reaction.

FIGURE 6.10 Helium is less dense than air.

Explain

Electron Configurations in Groups

Misconception Alert

Students may think that elements whose names are familiar are always more abundant on Earth than less familiar elements. Use the following data to show students why calling inner transition metals "rare-earth elements" is misleading. In Earth's crust, there is 1.7 ppb of osmium, 37 ppb of platinum, 67 ppb of mercury, 1700 ppb of tantalum, 6000 ppb of thorium, 10,000 ppb of lead, 60,000 ppb of cerium, and 34,000 ppb of lanthanum. Both platinum and mercury, which should be familiar elements to students, are present in much smaller quantities than thorium, cerium, and lanthanum—elements with which most students will not be familiar.

USE VISUALS Have students examine Figure 6.13. Emphasize the relationship between the position of an element in the periodic table and the element's atomic structure. **Ask** What do all the elements in Group 1A have in common? *(They all have one electron in the* s *orbital in the highest occupied energy level.)* **Ask** What do all the elements in Group 3A have in common? *(They all have one electron in a* p *orbital in the highest occupied energy level.)* To help students understand the instructions for writing electron configurations for elements in the *d* and *f* blocks, review the aufbau diagram in Lesson 5.2.

Extend

Connect to PHYSICS

Direct students' attention to Figure 6.12. Explain that uranium is a heavy metal element that can be used as a source of concentrated energy. Briefly describe how electricity can be generated from uranium in nuclear reactors. Have students write a persuasion paper on the risks or the rewards of increasing the production of nuclear power as an alternative energy source in the United States.

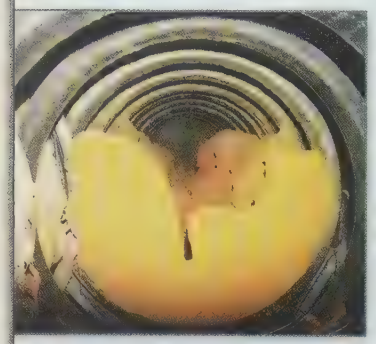

Figure 6.12 Uranium
Nuclear power plants use the inner transition metal uranium as fuel. The material shown is called yellowcake, an impure compound of uranium.

Transition Elements In the periodic table, the B group elements separate the A groups on the left side of the table from the A groups on the right side. Elements in the B groups are referred to as transition elements. There are two types of transition elements—transition metals and inner transition metals. They are classified based on their electron configurations.

The **transition metals** are the Group B elements that are usually displayed in the main body of a periodic table. Copper, silver, gold, and iron are transition metals. In atoms of a transition metal, the highest occupied *s* sublevel and a nearby *d* sublevel contain electrons. These elements are characterized by the presence of electrons in *d* orbitals.

The **inner transition metals** are the elements that appear below the main body of the periodic table. In atoms of these elements, the highest occupied *s* sublevel and a nearby *f* sublevel generally contain electrons. The inner transition metals are characterized by the presence of electrons in *f* orbitals. Uranium, an example of an inner transition metal, is shown in Figure 6.12.

Before scientists knew much about inner transition metals, people referred to them as rare-earth elements. This name is misleading because some inner transition metals are more abundant than other elements. Notice that some of the inner transition metals are not found in nature. These elements were prepared in laboratories using methods presented in Chapter 25.

Blocks of Elements If you consider both the electron configurations and the positions of the elements in the periodic table, another pattern emerges. In Figure 6.13, the periodic table is divided into sections, or blocks, that correspond to the highest occupied sublevels. The *s* block contains the elements in Groups 1A and 2A and the noble gas helium. The *p* block contains the elements in Groups 3A, 4A, 5A, 6A, 7A, and 8A, with the exception of helium. The transition metals belong to the *d* block, and the inner transition metals belong to the *f* block.

You can use Figure 6.13 to help determine electron configurations of elements. Each period on the periodic table corresponds to a principal energy level. Suppose an element is located in Period 3. You know that the *s* and *p* sublevels in energy levels 1 and 2 are filled with electrons. You then read across Period 3 from left to right to complete the configuration. For transition elements, electrons are added to a *d* sublevel with a principal energy level that is one less than the period number. For the inner transition metals, the principal energy level of the *f* sublevel is two less than the period number. This procedure gives the correct electron configurations for most atoms.

Figure 6.13 Electron Configurations
This diagram classifies elements into blocks according to sublevels that are filled or are filling with electrons.
Interpret Diagrams ***In the highest occupied energy level of a halogen atom, how many electrons are in the* p *sublevel?***

Professional Development Note

Using Shorthand Notation

The electron configurations of noble gases can be used to produce a shorthand notation for other electron configurations. The symbol of a noble gas in brackets represents its electron configuration. The configuration of sodium can be written as [Ne] $3s^1$. The electron configuration for zinc can be written as [Ar] $3d^{10}4s^2$.

Sample Problem 6.1

Using Energy Sublevels to Write Electron Configurations

Use Figure 6.9 and Figure 6.13 to write the electron configuration for nickel (Ni).

1 Analyze Identify the relevant concepts. For all elements, the atomic number is equal to the total number of electrons. For a representative element, the highest occupied energy level is the same as the number of the period in which the element is located. You can tell how many electrons are in this energy level from the group in which the element is located.

2 Solve Apply the concepts to this problem.

Use Figure 6.9 to identify where the atom is in the periodic table and the number of electrons in the atom.

Nickel is located in the fourth period and has 28 electrons.

Use Figure 6.13 to determine the electron configuration.

In nickel, the first three energy levels are full, so the configuration begins with $1s^2 2s^2 2p^6 3s^2 3p^6$. Next is $4s^2$ and $3d^8$. Put it all together: $1s^2 2s^2 2p^6 3s^2 3p^6 3d^8 4s^2$

9. Use Figure 6.9 and Figure 6.13 to write the electron configurations of the following elements:
- **a.** carbon
- **b.** strontium
- **c.** vanadium

10. List the symbols for all the elements whose electron configurations end as follows. *Note*: Each n represents an energy level.
- **a.** ns^2np^1
- **b.** ns^2np^5
- **c.** $ns^2np^6nd^2(n+1)s^2$

Remember that the principal energy level number for elements in the *d* block is always one less than the period number.

6.2 LessonCheck

11. Identify What types of information can be included in a periodic table?

12. List Into what four classes can elements be sorted based on their electron configurations?

13. Explain Why do the elements potassium and sodium have similar chemical properties?

14. Classify Identify each element as an alkali metal, an alkaline earth metal, or a halogen:
- **a.** barium
- **b.** chlorine
- **c.** lithium
- **d.** beryllium

15. Classify Based on the following electron configurations, identify each element as a representative element, transition metal, or noble gas.
- **a.** $1s^2 2s^2 2p^6 3s^2 3p^6 3d^{10} 4s^2 4p^6$
- **b.** $1s^2 2s^2 2p^6 3s^2 3p^6 3d^6 4s^2$
- **c.** $1s^2 2s^2 2p^6 3s^2 3p^2$

16. Describe How many electrons are in the highest occupied energy level of an element in Group 5A?

17. Identify Which of these elements are transition metals: Cu, Sr, Cd, Au, Al, Ge, Co?

Lesson Check Answers

11. symbols and names of the elements, atomic number and atomic mass, information about electron configuration

12. representative elements, noble gases, transition metals, and inner transition metals

13. They are in the same group and have the same number of electrons in the highest occupied energy level.

14. **a.** alkaline earth metal
b. halogen
c. alkali metal
d. alkaline earth metal

15. **a.** noble gas
b. transition metal
c. representative element

16. 5

17. Cu, Cd, Au, Co

Explain

Sample Practice Problem

Write the electron configuration for the following elements.

a. fluorine *([He] $2s^2 2p^5$)*

b. chromium *([Ar] $3d^5 4s^1$)*

Evaluate

Informal Assessment

Call out pairs of elements in the same group and have students write their electron configuration. If desired, this activity can be made into a game by dividing students into groups that compete to see who writes the correct configuration first. Then, have students complete the 6.2 Lesson Check.

Reteach

To reinforce the relationship between configurations and positions in the periodic table, have students work backward from electron configurations to identify their associated elements. Work with students to identify and locate the elements in the periodic table. Ask students to explain which parts of a configuration proved most useful for determining the identity.

Answers

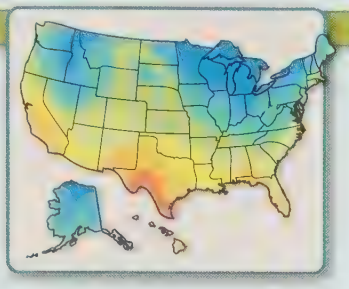
CHEMISTRY & YOU Have students read the opening paragraph. As a class, discuss the seasonal trends in weather typical for your region of the country. **Ask** How is knowing the trends in weather for a specific region helpful? *(Sample answer: It can help in determining the type of plants that will grow well in your yard.)* Have students consider how knowing trends in elemental properties might be helpful to scientists.

Access Prior Knowledge

Ask student volunteers to summarize what they have learned about the organization of the periodic table. Have students compare and contrast properties and characteristics of periods with those of groups.



IN ACADEMIC STANDARDS for SCIENCE

- Develop explanations based on reproducible data and observations gathered during laboratory investigations.
- Clearly communicate their ideas and results of investigations verbally and in written form using tables, graphs, diagrams, and photographs.

C.2.6 Use the periodic table and electron configurations to determine an element's number of valence electrons and chemical and physical properties.

6.3 Periodic Trends

C.2.6 Determine valence electrons and properties

CHEMISTRY & YOU

Q: *How are trends in the weather similar to trends in the properties of elements?* Although the weather changes from day to day. The weather you experience is related to your location on the globe. For example, Florida has an average temperature that is higher than Minnesota's. Similarly, a rain forest receives more rain than a desert. These differences are attributable to trends in the weather. In this lesson, you will learn how a property such as atomic size is related to the location of an element in the periodic table.

Trends in Atomic Size

What are the trends among the elements for atomic size?

One way to think about atomic size is to look at the units that form when atoms of the same element are joined to one another. These units are called molecules. Figure 6.14 shows models of molecules (molecular models) for seven nonmetals. Because the atoms in each molecule are identical, the distance between the nuclei of these atoms can be used to estimate the size of the atoms. This size is expressed as an atomic radius. The **atomic radius** is one half of the distance between the nuclei of two atoms of the same element when the atoms are joined.

The distances between atoms in a molecule are extremely small. So the atomic radius is often measured in picometers (pm). Recall that there are one trillion, or 10^{12}, picometers in a meter. The molecular model of iodine in Figure 6.14 is the largest. The distance between the nuclei in an iodine molecule is 280 pm. Because the atomic radius is one half the distance between the nuclei, a value of 140 pm (280/2) is assigned as the radius of the iodine atom. **In general, atomic size increases from top to bottom within a group and decreases from left to right across a period.**

Figure 6.14 Atomic Radii
This diagram compares the atomic radii of seven nonmetals.

Focus on ELL

1 CONTENT AND LANGUAGE Have students write the lesson title *Periodic Trends* in their vocabulary notebook. Have students determine the common definitions of each word and write them in their notebook. Have students predict the lesson content based on these definitions and what they have learned previously about the periodic table.

2 FRONTLOAD THE LESSON Provide four sets of photos of fashion trends from the 1950s, the 1970s, the 1990s, and the current decade. Ask students to identify the fashion trends for each decade. Explain that a trend is a pattern over time. Then ask students if they notice any similarities between clothes in the pictures. Explain that in fashion, and in element properties, trends repeat periodically.

3 COMPREHENSIBLE INPUT Play "The Elements" song written by Tom Lehler. Use this as a tool for engaging students' interest in the content. Point out that, even though the element names are never repeated, sections of the music are repeated. Similarly, trends in the periodic table are repeated in each period.

Interpret Graphs

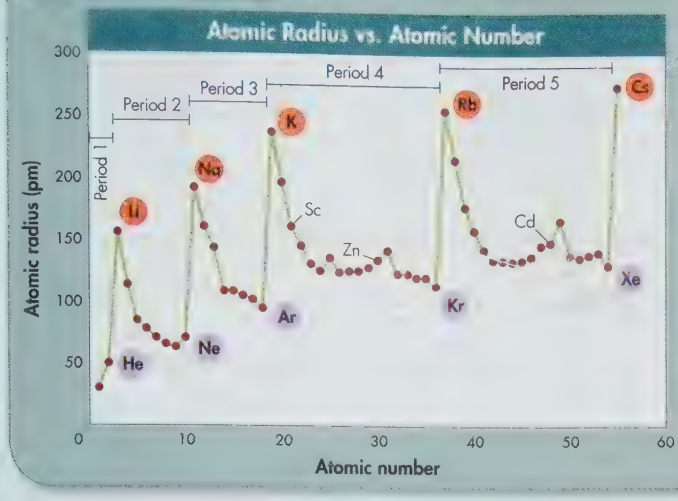

Figure 6.15 This graph plots atomic radius versus atomic number for elements with atomic numbers from 1 to 55.

a. Read Graphs Which alkali metal has an atomic radius of 238 pm?

b. Draw Conclusions Based on the data for alkali metals and noble gases, how does atomic size change within a group?

c. Predict Is an atom of barium, atomic number 56, smaller or larger than an atom of cesium (Cs)?

Group Trends in Atomic Size Look at the data for the alkali metals and noble gases in Figure 6.15. The atomic radius within these groups increases as the atomic number increases. This increase is an example of a trend.

As the atomic number increases within a group, the charge on the nucleus increases and the number of occupied energy levels increases. These variables affect atomic size in opposite ways. The increase in positive charge draws electrons closer to the nucleus. The increase in the number of occupied orbitals shields electrons in the highest occupied energy level from the attraction of protons in the nucleus. The shielding effect is greater than the effect of the increase in nuclear charge, so the atomic size increases.

Period Trends in Atomic Size Look again at Figure 6.15. With increasing atomic number, each element has one more proton and one more electron than the preceding element. Across a period, the electrons are added to the same principal energy level. The shielding effect is constant for all the elements in a period. The increasing nuclear charge pulls the electrons in the highest occupied energy level closer to the nucleus, and the atomic size decreases. Figure 6.16 summarizes the group and period trends in atomic size.

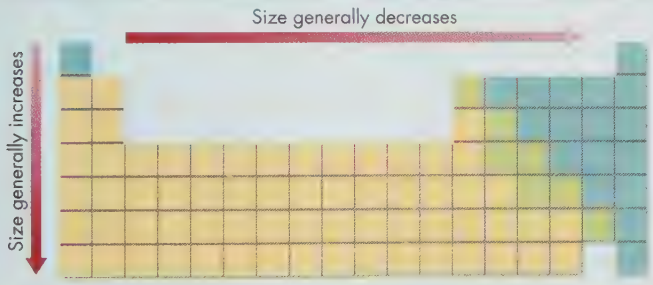

Figure 6.16 Trends in Atomic Size The size of atoms tends to decrease from left to right across a period and increase from top to bottom within a group.

Predict ***If a halogen and an alkali metal are in the same period, which one will have the larger radius?***

See periodic trends *animated online.*

Professional Development Note

Elements and the Big Bang

At the time of the Big Bang, the temperature was many billions of degrees. Neutrons, protons, and electrons may have formed within 10^{-4} second after the Big Bang, and the lightest nuclei formed within 3 minutes. Matter was in the form of plasma, a sea of positive nuclei and negative electrons. It took an estimated 500,000 years for electrons and nuclei to cool enough to form atoms. According to the Big Bang theory, Earth, with its wealth of chemical elements, formed from the debris of supernova explosions.

Foundations for Reading

BUILD VOCABULARY Have students' attention make a compare/contrast table for *cation* and *anion*, and use the table to decide which type of ion an element is likely to form.

READING STRATEGY Tell students that they will be learning about trends related to the location of elements in the periodic table. Guide students to read the visuals throughout the lesson closely, as the visuals summarize the trends described in the text.

Explain

Trends in Atomic Size

USE VISUALS Guide students' attention to Figure 6.14. **Ask** What is the main reason why a scientist cannot measure the diameter of a single atom? *(because an atom does not have a sharply defined border)* Discuss how measuring the distance between nuclei solves this problem. *(NOTE: In Chapter 8 there are formal definitions of* molecule *and* diatomic molecule. *The operational definition of a molecule should be sufficient for a discussion of atomic radii.)*

CRITICAL THINKING Emphasize the key roles electrical attraction and repulsion play within atoms and ions. Review the effects of increasing nuclear charge and changes in the shielding effect of electrons on the size of an atom: nuclear charge increases within groups and across periods; the shielding effect increases within groups, but it is constant across periods. Have students use these effects to describe the trends for atomic size within a period and within groups.

USE AN ANALOGY As an analogy to positions and trends in properties of elements in the periodic table, use seating charts and pricing data from local theaters or sports venues to discover trends. Instruct students to determine patterns that relate the position of a seat to its price. Students should discover that variables such as distance from the stage or field, location relative to the center of the action, and whether the view will be obstructed, all affect price.

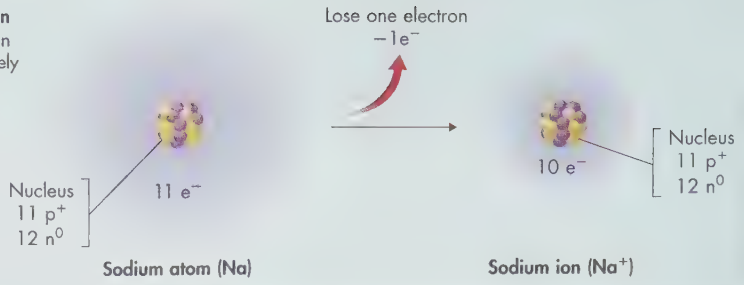
Ions

Class Activity



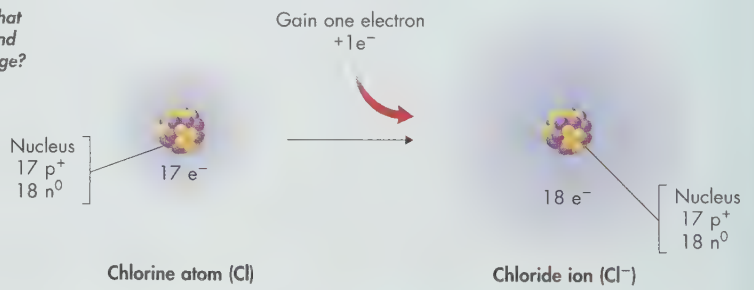
PURPOSE To give students practice identifying positive and negative ions

PROCEDURE Give students a list of elements. Ask them to locate each element in the periodic table, and decide whether its atoms are likely to form positive or negative ions. Have students make a list of elements that are likely to form positive ions and another list of elements that are likely to form negative ions.

Misconception Alert

Many students will associate the words "losing" and "gaining" with subtraction and addition, respectively. Make sure they understand that when an atom loses an electron, its charge becomes more positive, rather than more negative. Similarly, when an element gains an electron, it becomes more negative rather than more positive. It may be helpful to remind students that they are adding or subtracting the total *charge* of the electrons gained or lost, rather than the total *number* of electrons. For example, the elemental form has a charge of 0, and it loses a single electron, which has a charge of −1. The charge can be calculated as 0 − (−1) = 0 + 1 = +1. For chlorine, which gains an electron to become negative, the calculation would be 0 + (−1) = −1.

Figure 6.17 Cation Formation
When a sodium atom loses an electron, it becomes a positively charged ion.



Ions

How do ions form?

Some compounds are composed of particles called ions. An **ion** is an atom or group of atoms that has a positive or negative charge. An atom is electrically neutral because it has equal numbers of protons and electrons. For example, an atom of sodium (Na) has 11 positively charged protons and 11 negatively charged electrons. The net charge on a sodium atom is zero [(+11) + (−11) = 0].

Positive and negative ions form when electrons are transferred between atoms. Atoms of metals, such as sodium, tend to form ions by losing one or more electrons from their highest occupied energy levels. Figure 6.17 compares the atomic structure of a sodium atom and a sodium ion. In the sodium ion, the number of electrons (10) is not equal to the number of protons (11). Because there are more positively charged protons than negatively charged electrons, the sodium ion has a net positive charge. An ion with a positive charge is called a **cation.** The charge for a cation is written as a number followed by a plus sign. If the charge is 1, the number in 1+ is usually omitted from the symbol for the ion. For example, Na^{1+} is written as Na^{+}. Atoms of nonmetals, such as chlorine, tend to form ions by gaining one or more electrons. Figure 6.18 compares the atomic structure of a chlorine atom and a chloride ion. In a chloride ion, the number of electrons (18) is not equal to the number of protons (17). Because there are more negatively charged electrons than positively charged protons, the chloride ion has a net negative charge. An ion with a negative charge is called an **anion.** The charge for an anion is written as a number followed by a minus sign.

Figure 6.18 Anion Formation
When a chlorine atom gains an electron, it becomes a negatively charged ion.
Interpret Diagrams ***What happens to the protons and neutrons during this change?***

UbD Check for Understanding

How do ions form?

Assess students' knowledge about the formation of ions by asking them the following questions:

a. What occurs when an atom in Group 2 becomes an ion? *(It loses two electrons.)*

b. Is the ion that forms from a Group 2 atom called an anion or a cation? How do you know? *(It is a cation because it has a positive charge, +2.)*

ADJUST INSTRUCTION If students are confused, have them use a copy of the periodic table as a reference as they read the Ions lesson or as they review. Review the information provided in the Misconception Alert with students and show them how to use the group numbers shown in red in Figure 6.9 to help them determine the number of electrons lost or gained in groups 1A–7A. Note that determining the charge on transition metal ions will not be covered until Chapter 20.

Trends in Ionization Energy

What are the trends among the elements for first ionization energy?

Recall that electrons can move to higher energy levels when atoms absorb energy. Sometimes the electron has enough energy to overcome the attraction of the protons in the nucleus. The energy required to remove an electron from an atom is called **ionization energy.** This energy is measured when an element is in its gaseous state. The energy required to remove the first electron from an atom is called the first ionization energy. The cation produced has a 1+ charge. **First ionization energy tends to decrease from top to bottom within a group and increase from left to right across a period.**

Ionization energies can help you predict what ions an element will form. Look at the data in Table 6.1 for lithium (Li), sodium (Na), and potassium (K). The increase in energy between the first and second ionization energies is large. It is relatively easy to remove one electron from a Group 1A metal atom, but it is difficult to remove a second electron. This difference indicates that Group 1A metals tend to form ions with a 1+ charge.

Interpret Data

Ionization Energies of First 20 Elements (kJ/mol*)

Symbol	First	Second	Third
H	1312		
He (noble gas)	2372	5247

Ca	590	1146	4941

*An amount of matter equal to the atomic mass in grams

Table 6.1 The table compares ionization energies for elements with atomic numbers 1 through 20.

a. Read Tables What are the values for the first, second, and third ionization energies for sodium and aluminum?

b. Compare Is it easier to remove an electron from a sodium (Na) or aluminum (Al) atom? From Na^+ or Al^+? From Na^{2+} or Al^{2+}?

c. Draw Conclusions Which ion is more common—Na^{3+} or Al^{3+}?

Note: The second ionization energy is the energy needed to remove an electron from an ion with a 1+ charge. This produces an ion with a 2+ charge. The third ionization energy is the energy needed to remove an electron from an ion with a 2+ charge. This produces an ion with a 3+ charge.

Differentiated Instruction

L1 LESS PROFICIENT READERS Have students refer back to their KWL charts to review their notes on atomic structure. Have them use this information to identify three of the factors that affect ionization energy: nuclear charge, number of energy levels, and shielding.

ELL ENGLISH LANGUAGE LEARNERS Use student volunteers to set up a tug-of-war game that to demonstrate why the amount of energy needed to remove successive electrons increases. Assign one team to be "protons" and the other team to be "electrons." Show students how the amount of force exerted by the "protons" on the "electrons" increases as each "electron" is removed from the game, and that the "electrons" then have to pull harder against the "protons."

L3 ADVANCED STUDENTS Have students create a three-dimensional tactile or technological model that depicts the energy needed to remove an atom from an electron.

Explain

Trends in Ionization Energy

MAKE A CONNECTION Explain that ionization energy is a measure of the difficulty in removing an electron from the highest occupied energy level. **Ask** Why is the first ionization energy of a nonmetal much higher than that of an alkali metal? *(Because the nuclear charge increases from left to right across a period and the shielding effect stays the same, it is more difficult to remove an electron.)*

Misconception Alert

Some students may be tempted to place a negative sign on the ionization energy value. Students may confuse the phrase "losing an electron" with a negative energy value. Explain that the ionization energy is the energy change associated with removing one electron from a neutral atom. Explain that this energy value is always a positive number since energy must be added to the atom system to remove an electron. *(NOTE: The unit for ionization energy is kJ/mol. The footnote in Table 6.1 supplies an operational definition of mole, which is introduced in Lesson 10.1.)*

Explore

Teacher Demo

PURPOSE To help students understand the concepts of effective nuclear charge and electron shielding

PURPOSE Choose four students to be "protons" and four students to be "electrons." Construct a lithium "nucleus" by having three protons stand together at the front of the room. Note that for purposes of this demo, you are ignoring the neutrons.

- Place two electrons together at a short distance from the nucleus to represent the 1*s* electrons.
- Place the third electron a bit farther away to represent the 2*s* electron. You should be able to draw a line from the nucleus through the 1*s* electrons to the 2*s* electron.
- Point out that there are no other electrons between the 1*s* electrons and the nucleus.

Explain that these electrons experience the full impact of the 3+ charge because the third electron's "view" of the nucleus is partially blocked. Convey that this means the nucleus it is shielded somewhat from the full force of the 3+ charge.

Answers

c. Al^{3+}

Explain

Trends in Ionization Energy

USE VISUALS Direct students to Table 6.1, Figure 6.19, and their copy of the periodic table. Show students how to use Table 6.1 and the periodic table to create ordered pairs that are then plotted in the graph in Figure 6.19. Call out various atomic numbers and have students estimate the ionization energy, and vice versa. When students are comfortable reading the graph, direct them to answer the questions.

CRITICAL THINKING Challenge students to explain why the portion of the graph for Periods 4 and 5 is different from the portion of the graph for Periods 2 and 3. *(Periods 4 and 5 include transition metals, whose atoms have electrons in* d *orbitals.)*

Explore

Teacher Demo

PURPOSE Students observe the relative reactivities of magnesium and calcium and predict relative reactivities for other pairs of elements.

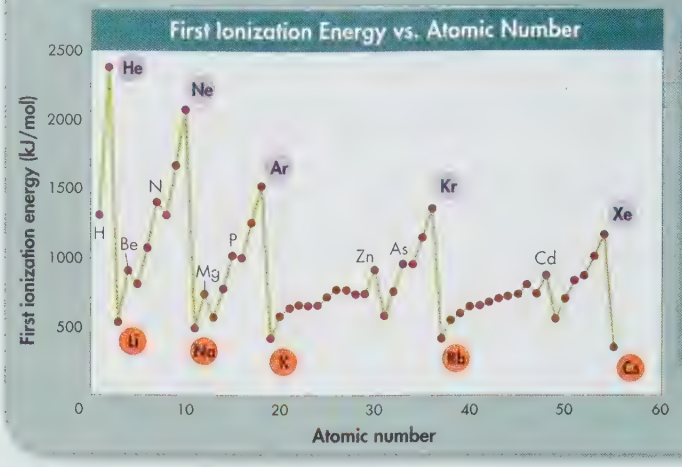
MATERIALS 20 mL 1*M* HCl, two 50-mL beakers, overhead projector, 20 cm magnesium ribbon, 1 g calcium

SAFETY Wear goggles for this demo.

PROCEDURE Pour 20 mL HCl into each beaker. Set the beakers on an overhead projector. Coil the magnesium ribbon and drop it into one beaker. Drop 1 g calcium into the other beaker. Compare the reaction rates in the two beakers. Point out the positions of the two elements in the periodic table, and relate the difference in reactivity to their first and second ionization energies. Ask students to predict the relative reactivities of other pairs of elements in Groups 1A and 2A.

EXPECTED OUTCOME The calcium fizzes in the HCl. The magnesium reacts more slowly with the HCl.

Interpret Graphs



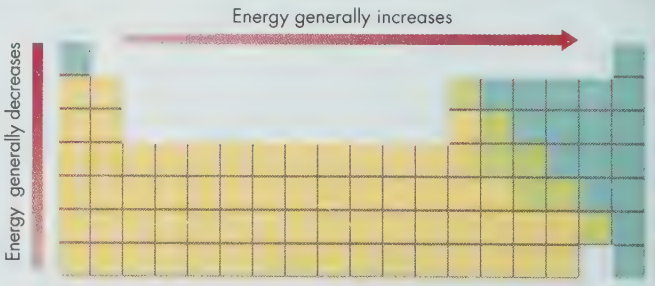


Figure 6.19 This graph reveals group and period trends for ionization energy.
a. Read Graphs Which element in Period 2 has the lowest first ionization energy? In Period 3?
b. Describe What are the group trends for first ionization energy for noble gases and alkali metals?
c. Predict If you drew a graph for second ionization energy, which element would you have to omit? Explain.

Group Trends in Ionization Energy Figure 6.19 is a graph of first ionization energy versus atomic number. Look at the data for the noble gases and the alkali metals. In general, first ionization energy decreases from top to bottom within a group. Recall that the atomic size increases as the atomic number increases within a group. As the size of the atom increases, nuclear charge has a smaller effect on the electrons in the highest occupied energy level. Less energy is required to remove an electron from this energy level, and the first ionization energy is lower.

Period Trends in Ionization Energy In general, the first ionization energy of representative elements tends to increase from left to right across a period. This trend can be explained by the nuclear charge and the shielding effect. The nuclear charge increases across the period, but the shielding effect remains constant. As a result, there is an increase in the attraction of the nucleus for an electron. Thus, it takes more energy to remove an electron from an atom. Figure 6.20 summarizes the group and period trends for first ionization energy.

Figure 6.20
Trends in First Ionization Energy
First ionization energy tends to increase from left to right across a period and decrease from top to bottom within a group.
Predict ***Which element would have the larger first ionization energy—an alkali metal in Period 2 or an alkali metal in Period 4?***

UbD **Check for Understanding**

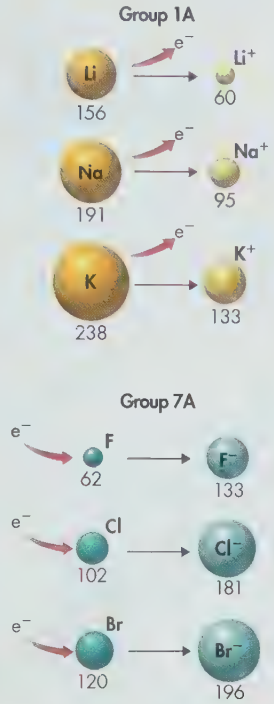
What are the trends among the elements for first ionization energy and ionic size and electronegativity?

Assess students' knowledge about the trends among the elements for first ionization energy by having students use arm gestures to answer the following questions. **Ask** In which direction on the periodic table does the first ionization energy generally increase in value? *(Accept arm gestures from left to right, and upward.)* **Ask** In which direction on the periodic table does the first ionization energy generally decrease in value? *(Accept arm gestures downward and from right to left.)*

ADJUST INSTRUCTION If students are having trouble answering, have them write some of the values in Table 6.1 on the element squares in a copy of the periodic table and examine their table for ionization patterns.

Trends in Ionic Size

What are the trends among the elements for ionic size?



During reactions between metals and nonmetals, metal atoms tend to lose electrons and nonmetal atoms tend to gain electrons. This transfer of electron has a predictable effect on the size of the ions that form. Cations are always smaller than the atoms from which they form. Anions are always larger than the atoms from which they form. **Ionic size tends to increase from top to bottom within a group. Generally, the size of cations and anions decrease from left to right across a period.**

Group Trends in Ionic Size Figure 6.21 compares the relative sizes of the atoms and ions for three metals in Group 1A—lithium (Li), sodium (Na), and potassium (K). For each of these elements, the ion is much smaller than the atom. For example, the radius of a sodium ion (95 pm) is about half the radius of a sodium atom (191 pm). When a sodium atom loses an electron, the attraction between the remaining electrons and the nucleus is increased. As a result, the electrons are drawn closer to the nucleus. Metals that are representative elements tend to lose all their outermost electrons during ionization. Therefore, the ion has one fewer occupied energy level.

The trend is the opposite for nonmetals, like the halogens in Group 7A. Look at Figure 6.21, and compare the relative sizes of the atoms and ions for fluorine (F), chlorine (Cl), and bromine (Br). For each of these elements, the ion is much larger than the atom. For example, the radius of a fluoride ion (133 pm) is more than twice the radius of a fluorine atom (62 pm). As the number of electrons increases, the attraction of the nucleus for any one electron decreases.

Period Trends in Ionic Size Look ahead at Figure 6.23. From left to right across a period, two trends are visible—a gradual decrease in the size of the positive ions (cations), followed by a gradual decrease in the size of the negative ions (anions). Figure 6.22 summarizes the group and period trends in ionic size.

Figure 6.21
Comparing Atomic and Ionic Sizes
This diagram compares the relative sizes of atoms and ions for selected alkali metals (Group 1A) and halogens (Group 7A). The numbers are measurements of the radii given in picometers (pm).

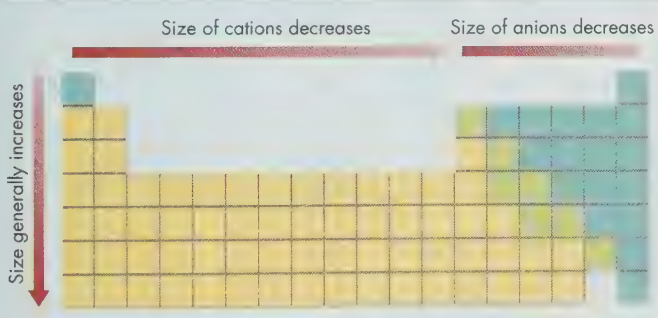


Figure 6.22 Trends in Ionic Size
The ionic radii for cations and anions decrease from left to right across periods and increase from top to bottom within groups.

Differentiated Instruction

L1 LESS PROFICIENT READERS Have students examine Table 6.2. Act out the meaning of electronegativity. Then have students predict if there are any elements other than noble gases that do not have a value for electronegativity. Guide students in researching their prediction. *(Predictions will vary; students will most likely find electronegativity tables lacking values for manmade elements with atomic numbers greater than 102.)* Note these elements rarely, if ever, have been demonstrated to form compounds because their atoms exist only momentarily due to their instability.

ELL SPECIAL NEEDS STUDENTS Provide tactile spherical models of various atoms. Have students arrange the models on a copy of the periodic table to visually convey the trend in ionic size.

L3 ADVANCED STUDENTS Have students research and describe the phenomenon of the lanthanide contraction. Ask them to discuss how the lanthanide contraction accounts for the fact that zirconium and hafnium have virtually the same atomic radius even though hafnium is below zirconium in Group 4B of the periodic table.

Explain

Trends in Ionic Size

MAKING CONNECTIONS Relate the periodic trends in ionic size to those discussed earlier for atomic size. Explain that the effective nuclear charge experienced by an electron in the highest occupied orbital of an atom or ion is equal to the total nuclear charge (the number of protons) minus the shielding effect due to electrons in lower energy levels. Point out that the effective nuclear charge determines the atomic and ionic radii. Explain that as you proceed from left to right in any given period, the principal quantum number, *n*, of the highest occupied energy level remains constant, but the effective nuclear charge increases. Therefore, atomic and ionic radii decrease as you move to the right in a period. Convey that in contrast, within any group, as you proceed from top to bottom, the effective nuclear charge remains nearly constant, but the principal quantum number, *n*, increases. Consequently, point out that atomic and ionic radii increase from top to bottom within a group.

Explore

Teacher Demo

PURPOSE Students observe an analogy for the effect of adding or removing electrons from an atom.

MATERIALS washers or other small circular items, smaller item (such as a button) to represent the nucleus, overhead projector

PROCEDURE On the overhead projector, make a circle of washers to represent an electron cloud in a neutral atom. The washers should be touching. Place the "nucleus" in the center of the circle. Add or subtract washers to mimic ion formation. With each change, adjust the circle so that the washers are still touching. Explain that the change in the diameter of the circle is analogous to the change in the effective attraction of the nuclear charge for electrons.

Answers

FIGURE 6.19

a. lithium; sodium

b. First ionization energy decreases as atomic number increases.

c. Hydrogen; it has only one electron.

LESSON 6.3

Explore

Trends in Ionic Size

QuickLab

OBJECTIVE After completing this activity, students will be able to identify periodic trends in ionic size.

SKILLS FOCUS Using tables and graphs, predicting, drawing conclusions

PREP TIME none

CLASS TIME 40 minutes

TEACHING TIPS If time is too limited for students to make the graph, use Figure 6.23 to answer Questions 1, 2, 4, and 5. You may want to reference the radii diagrams in the Elements Handbook on R3, R7, R11, R15, R21, R25, and R29.

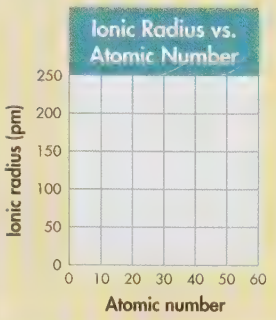
EXPECTED OUTCOME Ionic radii increase from top to bottom within a group. The radii of cations and anions decrease from left to right across a period.

ANALYZE AND CONCLUDE

1. Cations are smaller than their atoms; anions are larger than their atoms.
2. Ionic radii increase from top to bottom within a group of metals or within a group of nonmetals.
3. Two portions of the curve slope down from left to right.
4. The trend is similar for the periods.
5. The radii increase within a group because the number of occupied energy levels increases. The radii of cations decrease across a period because the nuclear charge increases, the shielding effect is constant, and the number of electrons decreases. (The effect is smaller with anions because the number of electrons increases.)

FOR ENRICHMENT Have students use the graph on page R37 to describe the periodic trend in atomic size for transition metals. Have students examine how the trend for transition metals compares to the trend for representative elements.

QuickLab



Purpose To use a graph to identify period and group trends

Materials
- graph paper
- pencil

Periodic Trends in Ionic Radii

Procedure

Use the data presented in Figure 6.23 to plot ionic radius versus atomic number.

Analyze and Conclude

1. **Compare** How does the size change when an atom forms a cation and when an atom forms an anion?
2. **Describe** How do the ionic radii vary within a group of metals? How do they vary within a group of nonmetals?
3. **Describe** What is the shape of a portion of the graph that corresponds to one period?
4. **Compare and Contrast** Is the trend across a period similar or different for Periods 2, 3, 4, and 5?
5. **Explain** Propose explanations for the trends you have described for ionic radii within groups and across periods.

Figure 6.23 Atomic and Ionic Radii
Atomic and ionic radii are an indication of the relative size of atoms and ions. The data listed are reported in picometers (pm).

Focus on ELL

4 LANGUAGE PRODUCTION Have students work in groups or pairs to complete the lab. Review plotting data on a coordinate grid with the class. Pair students with higher proficiency in English with students of lower proficiency.

BEGINNING: LOW/HIGH Help students create a set of ordered pairs to plot on the graph. Use gestures to visually show how to plot an ordered pair on a coordinate grid.

INTERMEDIATE: LOW/HIGH Paraphrase the questions in the Analyze and Conclude section. Guide students to answer one question at a time.

ADVANCED: LOW/HIGH Direct students to read the graph aloud, pointing out trends and making predictions prior to answering the questions.

Trends in Electronegativity

What are the trends among the elements for electronegativity?

In Chapters 7 and 8, you will study two types of bonds that can exist in compounds. Electrons are involved in both types of bonds. There is a property that can be used to predict the type of bond that will form during a reaction. This property is called electronegativity. **Electronegativity** is the ability of an atom of an element to attract electrons when the atom is in a compound. Scientists use factors such as ionization energy to calculate values for electronegativity.

Table 6.2 lists electronegativity values for representative elements in Groups 1A through 7A. The elements are arranged in the same order as in the periodic table. The noble gases are omitted because they do not form many compounds. The data in Table 6.2 is expressed in Pauling units. Linus Pauling won a Nobel Prize in Chemistry for his work on chemical bonds. He was the first to define electronegativity.

In general, electronegativity values decrease from top to bottom within a group. For representative elements, the values tend to increase from left to right across a period. Metals at the far left of the periodic table have low values. By contrast, nonmetals at the far right (excluding noble gases) have high values. The electronegativity values among the transition metals are not as regular.

The least electronegative element in the table is cesium, with an electronegativity value of 0.7. It has the least tendency to attract electrons. When it reacts, it tends to lose electrons and form cations. The most electronegative element is fluorine, with a value of 4.0. Because fluorine has such a strong tendency to attract electrons, when it is bonded to any other element it either attracts the shared electrons or forms an anion.

Figure 9.24, on the next page, summarizes several trends that exist among the elements. Refer to this figure as you study the periodic trends presented in this chapter.

Table 6.2

Electronegativity Values for Selected Elements

H						
2.1						
Li	Be	B	C	N	O	F
1.0	1.5	2.0	2.5	3.0	3.5	4.0
Na	Mg	Al	Si	P	S	Cl
0.9	1.2	1.5	1.8	2.1	2.5	3.0
K	Ca	Ga	Ge	As	Se	Br
0.8	1.0	1.6	1.8	2.0	2.4	2.8

0.8	1.0	1.7	1.8	1.9	2.1	2.5
Cs	Ba	Tl	Pb	Bi		
0.7	0.9	1.8	1.9	1.9		

Focus on ELL

4 ENABLE LANGUAGE PRODUCTION Have students work in small groups to complete the Small-Scale Lab on page 184. Make sure each group has ELLs of varied language proficiencies, so that more proficient students can help less proficient ones. Have students work according to their proficiency level.

BEGINNING

LOW Model the procedure and have students mimic you. Show students how to read measures from measuring tools.

HIGH Rephrase steps 1 and 3 in the procedure as several single-direction steps.

INTERMEDIATE: LOW/HIGH Restate the Analyze and Conclude questions in simpler terms. Allow students to orally respond to the Analyze and Conclude questions.

ADVANCED: LOW/HIGH Have students paraphrase the questions in Analyze and Conclude and You're the Chemist and read them aloud to students with lower English proficiencies.

Explore

Trends in Electronegativity

START A CONVERSATION Lead a class discussion on periodic and group trends in electronegativities. Point out that electronegativity values help chemists predict the type of bonding that exists between atoms in compounds. **Ask** Why are the noble gases not included in a discussion on electronegativity? *(because they form very few compounds)* **Ask** Which element represented in Table 6.2 is the most electronegative and which is the least electronegative? *(fluorine; cesium)* Stress that electronegativity is a calculated value rather than a measured quantity.

APPLY CONCEPTS Explain that the values for *electronegativity* are often based on values for ionization energy and electron affinity. Explain that ionization energy is a measure of an atom's ability to lose electrons and electron affinity is a measure of an atom's ability to gain electrons.

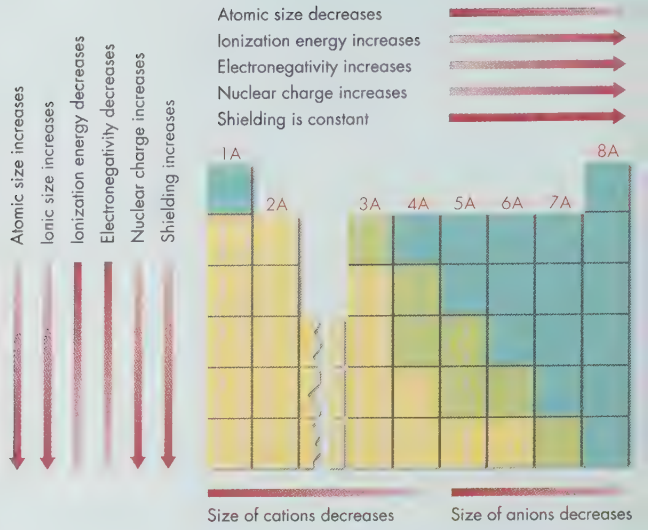
Misconception Alert

Students often confuse the meanings of *electronegativity* and *ionization energy*. As a class, brainstorm ideas for how to remember the meanings of each term. Then have students pictorially illustrate both concepts.

Explain

USE VISUALS Direct students' attention to Figure 6.24. Point out that this diagram incorporates information from several diagrams earlier in the chapter. Lead a discussion as to whether students find this or earlier diagrams more helpful, and why.

CHEMISTRY & YOU Trends in atomic size, ionization energy, ionic size, and electronegativity can be idendified with the help of the periodic table.



Evaluate

Informal Assessment

Assign each student two elements in the same group and have the student compare the elements in terms of atomic radius, ionic radius, ionization energy, and electronegativity. For successful students, repeat the exercise with a metal and nonmetal from the same period. Have students write general statements to summarize the trends revealed by these comparisons. Then, have students complete the 6.3 Lesson Check.

Reteach

Review the terms used in Figure 6.24. Then, use the periodic table and the terms to play a version of "I'm thinking of . . . ." For example, choose fluorine and say you are thinking of an element that has a very small atomic size and a very high electronegativity. Let students guess, and then discuss the correct answer. Have students continue the game in small groups.

CHEMISTRY & YOU

Q: *You are familiar with using a weather map to identify trends in the weather. For example, certain areas are typically warmer than other areas. What trends in the properties of elements can you identify with the help of the periodic table?*

Figure 6.24 Summary of Periodic Trends
Trends for atomic size, ionization energy, ionic size, and electronegativity vary within groups and across periods. The trends that exist among these properties can be explained by variations in atomic structure. The increase in nuclear charge within groups and across periods explains many trends. Within groups, an increase in the number of occupied energy levels and an increase in shielding both have a significant effect on each trend.
Interpret Diagrams ***Which properties tend to decrease across a period? Which properties tend to decrease down a group?***

6.3 LessonCheck

18. Review How does atomic size change within groups and across periods?

19. Explain When do ions form?

20. Summarize How do first ionization energies vary within groups and across periods?

21. Describe Compare the size of ions to the size of the atoms from which they form.

22. Review How do electronegativity values vary within groups and across periods?

23. Explain In general, how can the periodic trends displayed by elements be explained?

24. Sequence Arrange these elements in order of decreasing atomic size: sulfur, chlorine, aluminum, and sodium. Does your arrangement demonstrate a periodic trend or a group trend?

25. Identify Which element in each pair has the larger first ionization energy?
a. sodium, potassium
b. magnesium, phosphorus

Lesson Check Answers

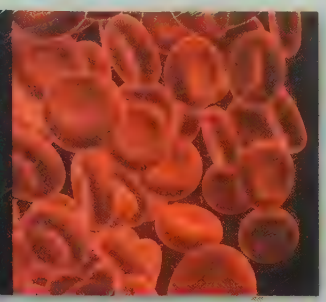
18. Atomic size generally increases within a group and decreases from left to right across a period.

19. Ions form when electrons are transferred between atoms.

20. First ionization energy generally decreases within a group and increases from left to right across a period.

21. Anions are larger and cations are smaller than the atoms from which they form.

22. Electronegativity values generally decrease from top to bottom within a group and increase from left to right across a period.

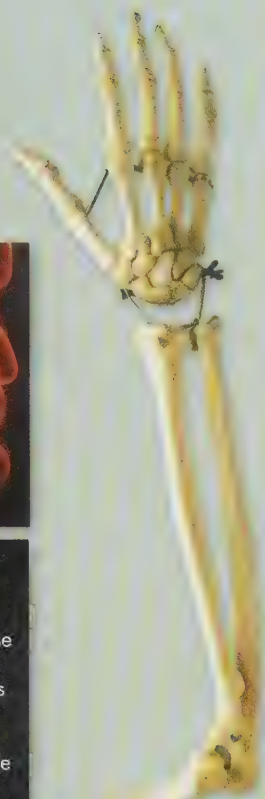


23. The trends can be explained by variations in atomic structure.

24. sodium, aluminum, sulfur, chlorine; periodic trend

25. **a.** sodium **b.** phosphorus

Elements of Life



Like everything else in the universe, your body is made up of elements. Your body uses these elements for different functions. Roughly 97 percent of the human body consists of just four elements: oxygen, carbon, hydrogen, and nitrogen. The remaining 3 percent contains about 20 other elements that are essential to life.

CIRCULATORY SYSTEM Iron and oxygen are critical to the circulatory system—the system that carries blood throughout the body. Iron, which is contained in red blood cells, helps transport oxygen from the lungs to other cells in your body. Two other elements—copper and cobalt—are necessary for the formation of red blood cells.

NERVOUS SYSTEM Sodium and potassium are essential to the nervous system, in particular the nerve cells. These elements allow your brain to communicate with other tissues in your body. Other elements that are important for proper nervous system function include calcium, chlorine, zinc, and magnesium.

SKELETAL SYSTEM Your bones and teeth—two components of the skeletal system—are largely comprised of calcium and phosphorus, which give bones and teeth their strength. Fluorine, boron, magnesium, and silicon are also important for bone growth and for maintaining bone strength.

Take It Further

1. **Describe** Use the information provided on page R1 to estimate the composition of the human body in terms of metals, nonmetals, and metalloids.
2. **Predict** The elements sodium, magnesium, potassium, and calcium are the most abundant metals in the human body and are present as ions. What is the charge of each of these ions?
3. **Sequence** Use Figure 6.23 to list the ions in Question 2 from smallest to largest.

Differentiated Instruction

L1 STRUGGLING STUDENTS Help students make a circle graph of the distribution of elements in living organisms as a percentage of body weight. Write these numbers on the board for them to use: oxygen, 61%; carbon, 23%; nitrogen, 2.6%; hydrogen, 10%, and other elements, 3.4%. You may wish to have students use a graphing program to make the graphs, or have them make the graph on the board as a class project.

LPR LESS PROFICIENT READERS Have students read the feature together with a partner. First, have students read a paragraph independently, and then have them discuss what they have read with their partners. Afterwards, discuss the feature together as a class.

L3 ADVANCED STUDENTS Ask students to research and write a report, including tables, that distinguishes between the percentages by *mass* and percentages by *number of atoms* of each of the four main elements in the body.

CHEMISTRY & YOU Have students look at the photos and read about the Elements of Life. Engage students in a conversation of ways the four main elements of life—hydrogen, oxygen, carbon, and nitrogen—are a part of their everyday lives. Students should realize that everything they do, every moment of the day, involves these elements. Pose the following question to students: *How many different encounters have you had with these four elements today?* You may need to assist students in the following ways:

- activities involving eating, drinking, or performing personal hygiene tasks
- activities involved in getting to school
- activities the body carries out to live
- objects encountered in nature

Explain

START A CONVERSATION Explain to students that about 97% of the atoms in the body are either hydrogen, oxygen, carbon, or nitrogen. Encourage them to think about what properties might make these elements so special. Explain that in later chapters they will learn about how atoms combine by forming chemical bonds. Atoms of these four elements are small and light. Also, the arrangement of electrons in the atoms allows them to form bonds in such a way that the atoms can combine into the large, stable molecules necessary to carry out life functions.

Extend

Connect to PHYSIOLOGY

Point out to students that even though hydrogen, oxygen, carbon, and nitrogen are by far the most common atoms in organisms, they are not the *only* atoms that are necessary for life. Have students research the relative percentages of all the different elements present in the human body and to present their findings to the class.

Answers

FIGURE 6.24 sizes of atoms and ions; ionization energy and electronegativity

TAKE IT FURTHER

1. metals: 2%; nonmetals: 98%; metalloids: 0%
2. sodium: 1+; magnesium: 2+; potassium: 1+; calcium: 2+
3. magnesium, sodium, calcium, potassium

Explore

Small-Scale Lab

OBJECTIVE After completing this activity, students should be able to build concrete models to reinforce periodic trends. They should also be able to apply a procedure to a new variable and design a model on their own.

PREP TIME 10 minutes

CLASS TIME 40 minutes

MATERIALS 96-well spot plates, straws, scissors, metric rulers, permanent fine-line markers

ADVANCE PREPARATION Straws with a 1/4-inch diameter fit snugly in the wells.

TEACHING TIPS Students can use colored straws to color code groups or periods. If you do not have spot plates, press a lump of clay the size of a golf ball flat on a table with a block of wood. Students can mark out a 1-cm square grid and insert the straws in the clay.

EXPECTED OUTCOME Students produce 3-D models for periodic trends.

ANALYZE AND CONCLUDE

1. fluorine
2. Electronegativity generally increases from left to right along a period.
3. Metals, which are on the left side of the table, have lower electronegativity values than nonmetals, which are on the right.
4. Electronegativity generally increases from bottom to top within a group. Except for boron, the rest of Group 3A shows a reverse in this trend.
5. Hydrogen is placed in Group 1A based on its electron configuration, but is classified as a nonmetal.

FOR ENRICHMENT Have students use the data on page R37 to make a 3-D model of trends in atomic size for transition metals.

YOU'RE THE CHEMIST

1. Students divide the values of first ionization energies by 300 and measure the appropriate length of straws.
2. Students must determine their own scale before they begin. Students often use two wells to represent both ionic and atomic radii. Other students cut a straw to a length that represents the larger radius of an atom and mark the straw to show the smaller radius of the corresponding cation.
3. The value for xenon is similar to iodine, which is consistent with the general trend. Based on this value, xenon appears to have the ability to attract electrons and form compounds.

Small-Scale Lab

Periodicity in Three Dimensions

Purpose

To build three-dimensional models for periodic trends

Materials

- 96-well spot plate
- straws
- scissors
- metric ruler
- permanent fine-line marker

Procedure

1. Measure the depth of a well in the spot plate by inserting a straw into a well and holding the straw upright as shown in the photograph. Make a mark on the straw at the point where the straw meets the surface of the plate. Measure the distance from the end of the straw to the mark in centimeters (cm). Record this distance as well depth.

2. Cut the straw to a length that is 4.0 cm plus well depth. The straw will extend exactly 4.0 cm above the surface of the plate.

3. Fluorine has an electronegativity value of 4.0. On a scale of 1.0 cm equals 1.0 unit of electronegativity, the portion of the straw that extends above the surface of the plate represents the electronegativity value for fluorine. Using the same scale, cut straws to represent the electronegativity values for all the elements listed in Table 6.2. Remember to add the well depth to the electronegativity value before cutting a straw. As you cut the straws, mark each straw with the chemical symbol of the element that the straw represents.

4. Arrange the straws in the spot plate in rows and columns to match the locations of the elements in the periodic table.

Analyze and Conclude

1. Use Models Which element represented in your model is the most electronegative?

2. Use Models Based on your model, what is the general trend in electronegativity from left to right across a period?

3. Interpret Diagrams Relate the trend in electronegativity across a period to the location of metals and nonmetals in the periodic table.

4. Use Models Based on your model, what is the general trend in electronegativity within a group? Are there any notable exceptions?

5. Explain Why do you think that the electronegativity value for hydrogen is so high given its location in the periodic table?

You're the Chemist

1. Design an Experiment Construct a similar three-dimensional model for first ionization energies. Use the data in Table 6.1 to construct the model. Use a scale of 1.0 cm equals 300 kJ/mol.

2. Design an Experiment Design and construct a three-dimensional model that shows trends in atomic and ionic radii for the elements in Groups 1A and 7A. Devise a way to display both ionic and atomic radii in the same model.

3. Analyze Data Xenon has an electronegativity value of 2.6. Cut and place a straw in your first model to represent xenon. Does xenon support the trend for electronegativity across a period? Is xenon likely to form compounds? Explain your answers.

6 Study Guide

BIG IDEA ELECTRONS AND THE STRUCTURE OF ATOMS

Periodic tables may contain each element's name, symbol, atomic number, atomic mass, and number of electrons in each energy level. The electron configuration of an element can be determined based on the location of an element in the periodic table. Atomic size, ionization energy, ionic size, and electronegativity are trends that vary across periods and groups of the periodic table. These trends can be explained by variations in atomic structure. The increase in nuclear charge within groups and across periods explains many trends. Within groups, an increase in electron shielding has a significant effect on these trends.

6.1 Organizing the Elements

- Early chemists used the properties of elements to sort them into groups.
- Mendeleev arranged the elements in his periodic table in order of increasing atomic mass.
- In the modern periodic table, elements are arranged in order of increasing atomic number.
- Three classes of elements are metals, nonmetals, and metalloids.

- periodic law (162)
- metal (165)
- nonmetal (165)
- metalloid (166)

6.2 Classifying the Elements

- The periodic table usually displays the symbols and names of elements, along with information about the structure of their atoms.
- Elements can be sorted into noble gases, representative elements, transition metals, or inner transition metals based on their electron configurations.

- alkali metal (167)
- alkaline earth metal (167)
- halogen (167)
- noble gas (170)
- representative element (171)
- transition metal (172)
- inner transition metal (172)

6.3 Periodic Trends

- In general, atomic size increases from top to bottom within a group and decreases from left to right across a period.
- Positive and negative ions form when electrons are transferred between atoms.
- First ionization energy tends to decrease from top to bottom within a group and increase from left to right across a period.
- Ionic size tends to increase from top to bottom within a group. Generally, the size of cations and anions decrease from left to right across a period.
- In general, electronegativity values decrease from top to bottom within a group. For representative elements, the values tend to increase from left to right across a period.

- atomic radius (174)
- ion (176)
- cation (176)
- anion (176)
- ionization energy (177)
- electronegativity (181)

UbD Performance Tasks

EXPOSED TO THE ELEMENTS Have students design a periodic table that contains an eighth period based on their knowledge of how the current table is constructed and their understanding of electron configuration. Students should accompany their table with an explanation of the design. Tables should include space for elements containing a 5*f* sublevel and correctly indicate appropriate atomic numbers for the new elements. Students should also predict the classifications of the new elements based on existing classifications (transition metals, noble gases, alkali metals, and so on).

PERIODIC TRENDS Have students use presentation software to create a multi-slide display about trends in the periodic table. Encourage the use of animations to make their display more appealing and understandable.

Evaluate

Review and Assessment Materials

WALK-THRU TUTORIALS Have students review writing electron configurations in an animated step-by-step tutorial that explains the problem-solving strategy in detail.

PROBLEM SETS Have students practice more periodic table problems by using the Chapter 6 Online Problem Set.

MATH SKILLS REVIEW Have struggling students practice solving algebraic equations by using the MathXL learning module.

VIRTUAL LABS Have students complete a virtual lab as an in-class or take-home assignment to help reinforce their understanding of trends exhibited by the elements in the periodic table.

Study Tip

REWRITE CLASS NOTES Remind students to take notes during class of the key points that are discussed, and to rewrite the notes so that they are organized and legible. Students can use the textbook to fill in any important points that they missed. They can use the organized notes to review for quizzes and tests.

If your class subscribes to the Interactive Textbook, your students can go online to access an interactive version of the Student Edition and a self-test.

Answers

LESSON 6.1

26. so that undiscovered elements with similar properties could be placed in the same group

27. The close match between the predicted properties and the actual properties of gallium helped gain wider acceptance for Mendeleev's periodic table.

28. a periodic repetition of their physical and chemical properties

29. Yes; both carbon and silicon are in Group 4A, and each has four electrons in the highest occupied energy level.

30. **a.** nonmetal **b.** nonmetal **c.** metal **d.** nonmetal **e.** metal

31. Metalloids have properties that are similar to those of metals and nonmetals. How a metalloid behaves depends on the conditions.

LESSON 6.2

32. Group 1A, Group 2A, Group 7A, and Group 8A, respectively

33. Na, Mg, Cl

34. helium

35. aluminum

36. **a.** $1s^2 2s^2 2p^1$
b. $1s^2 2s^2 2p^6 3s^2 3p^6 3d^{10} 4s^2 4p^3$
c. $1s^2 2s^2 2p^5$
d. $1s^2 2s^2 2p^6 3s^2 3p^6 3d^{10} 4s^2$
e. $1s^2 2s^2 2p^6 3s^2 3p^1$

37. **a.** Ar: $1s^2 2s^2 2p^6 3s^2 3p^6$
b. Si: $1s^2 2s^2 2p^6 3s^2 3p^2$
c. Mg: $1s^2 2s^2 2p^6 3s^2$

LESSON 6.3

38. **a.** sodium **b.** strontium **c.** germanium **d.** selenium

39. The first ionization energy is the energy needed to remove a first electron from an atom. The second ionization energy is the energy needed to remove a second electron.

40. **a.** boron **b.** magnesium **c.** aluminum

41. **a.** Sr, Mg, Be **b.** Cs, Ba, Bi **c.** Na, Al, S

42. It is relatively easy to remove the first electron from an alkali metal atom; it is much more difficult to remove the second.

43. The ionic radius of a metal cation is smaller than the atomic radius of the metal atom.

44. **a.** Na **b.** S^2 **c.** I^- **d.** Al

45. **a.** F **b.** N **c.** Mg **d.** As

46. Noble gases, with rare exception, do not form compounds.

47. **a.** O **b.** F **c.** O **d.** S

48. a and c

6 Assessment

* Solutions appear in Appendix E

Lesson by Lesson

6.1 Organizing the Elements

26. Why did Mendeleev leave spaces in his periodic table?

* **27.** What effect did the discovery of gallium have on the acceptance of Mendeleev's table?

28. What pattern is revealed when the elements are arranged in a periodic table in order of increasing atomic number?

29. Based on their locations in the periodic table, would you expect carbon and silicon to have similar properties? Explain your answer.

30. Identify each property below as more characteristic of a metal or a nonmetal.
a. a gas at room temperature
b. brittle
c. malleable
d. poor conductor of electric current
e. shiny

31. In general, how are metalloids different from metals and nonmetals?

6.2 Classifying the Elements

32. Where are the alkali metals, the alkaline earth metals, the halogens, and the noble gases located in the periodic table?

33. Which of the following are symbols for representative elements: Na, Mg, Fe, Ni, Cl?

* **34.** Which noble gas does not have eight electrons in its highest occupied energy level?

35. Which of these metals isn't a transition metal?
a. aluminum **c.** iron
b. silver **d.** zirconium

36. Use Figure 6.13 to write the electron configurations of these elements.
a. boron **c.** fluorine **e.** aluminum
b. arsenic **d.** zinc

37. Write the electron configurations of these elements.
a. the noble gas in Period 3
b. the metalloid in Period 3
c. the alkali earth metal in Period 3

6.3 Periodic Trends

* **38.** Which element in each pair has atoms with a larger atomic radius?
a. sodium, lithium
b. strontium, magnesium
c. carbon, germanium
d. selenium, oxygen

39. Explain the difference between the first and second ionization energy of an element.

40. Which element in each pair has a greater first ionization energy?
a. lithium, boron
b. magnesium, strontium
c. cesium, aluminum

41. Arrange the following groups of elements in order of increasing ionization energy:
a. Be, Mg, Sr **b.** Bi, Cs, Ba **c.** Na, Al, S

42. Why is there a large increase between the first and second ionization energies of the alkali metals?

* **43.** How does the ionic radius of a typical metal compare with its atomic radius?

44. Which particle has the larger radius in each atom/ion pair?
a. Na, Na^+ **c.** I, I^-
b. S, S^{2-} **d.** Al, Al^{3+}

45. Which element in each pair has a higher electronegativity value?
a. Cl, F **c.** Mg, Ne
b. C, N **d.** As, Ca

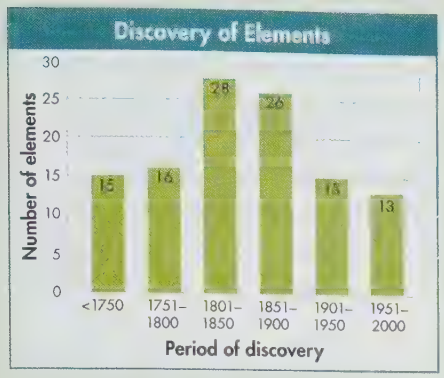
46. Why are noble gases not included in Table 6.2?

* **47.** When the elements in each pair are chemically combined, which element in each pair has a greater attraction for electrons?
a. Ca or O **c.** H or O
b. O or F **d.** K or S

48. For which of these properties does lithium have a larger value than potassium?
a. first ionization energy
b. atomic radius
c. electronegativity
d. ionic radius

Focus on ELL

5 ASSESS UNDERSTANDING Practice for higher-level assessment questions by assigning students Think Critically and Enrichment problems.



BEGINNING: LOW/HIGH Explain the meaning of the boldface words that begin each problem. Explain that these key words help prepare students for the type of thought process needed to solve each problem.

INTERMEDIATE: LOW/HIGH Help students break apart multi-part questions into several simpler questions. Guide students to answer one part of the question at a time. Allow students to answer the questions orally and then help them to write their responses as simple sentences.

ADVANCED: LOW/HIGH Have students read each question, considering the sentence they just read before moving to the next part of the problem. Then, have them write bulleted concepts they need to examine prior to answering the question.

Understand Concepts

49. The bar graph shows how many elements were discovered before 1750 and in each 50-year period between 1750 and 2000.

- **a.** In which 50-year period were the most elements discovered?
- **b.** How did Mendeleev's work contribute to the discovery of elements?
- **c.** What percent of these elements were discovered by 1900?

50. Write the symbol of the element or elements that fit each description.

- **a.** a nonmetal in Group 4A
- **b.** the inner transition metal with the lowest atomic number
- **c.** all of the nonmetals for which the atomic number is a multiple of five
- **d.** a metal in Group 5A

***51.** In which pair of elements are the chemical properties of the elements most similar? Explain your reasoning.

- **a.** sodium and chlorine
- **b.** nitrogen and phosphorus
- **c.** boron and oxygen

52. Explain why fluorine has a smaller atomic radius than both oxygen and chlorine.

53. Would you expect metals or nonmetals in the same period to have higher ionization energies? Give a reason for your answer.

54. In each pair, which ion is larger?

a. Ca^{2+}, Mg^{2+} **b.** Cl^-, P^{3-} **c.** Cu^+, Cu^{2+}

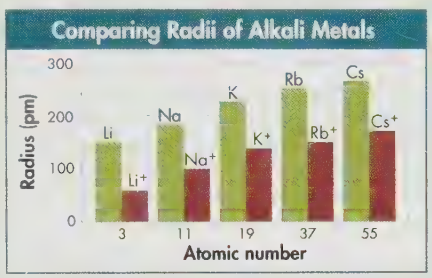
55. Use the graph in Figure 6.15 to estimate the atomic radius of the indium atom.

***56.** List the symbols for all the elements with electron configurations that end as follows. *Note:* Each *n* represents an energy level.

a. ns^1 **b.** ns^2np^4 **c.** ns^2nd^{10}

57. Explain why there should be a connection between an element's electron configuration and its location on the periodic table.

58. Which equation represents the first ionization of an alkali metal atom?



- **a.** $Cl \longrightarrow Cl^+ + e^-$
- **b.** $Ca \longrightarrow Ca^+ + e^-$
- **c.** $K \longrightarrow K^+ + e^-$
- **d.** $H \longrightarrow H^+ + e^-$

59. What trend is demonstrated by the following series of equations?

$Li + 520\ kJ/mol \longrightarrow Li^+ + e^-$
$O + 1314\ kJ/mol \longrightarrow O^+ + e^-$
$F + 1681\ kJ/mol \longrightarrow F^+ + e^-$
$Ne + 2080\ kJ/mol \longrightarrow Ne^+ + e^-$

***60.** There is a large jump between the second and third ionization energies of magnesium. There is a large jump between the third and fourth ionization energies of aluminum. Explain these observations.

61. The bar graph shows the relationship between atomic and ionic radii for Group 1A elements.

- **a.** Describe and explain the trend in atomic radius within the group.
- **b.** Explain the difference between the size of the atoms and the size of the ions.

62. Locate each of the following elements in the periodic table and decide whether its atoms are likely to form anions or cations.

- **a.** sodium
- **b.** fluorine
- **c.** calcium
- **d.** potassium
- **e.** iodine
- **f.** beryllium
- **g.** oxygen
- **h.** lithium

ASSESSMENT

UNDERSTAND CONCEPTS

49. **a.** 1801–1850
b. Mendeleev's periodic table helped scientists predict the existence of undiscovered elements.
c. 75%

50. **a.** C **b.** La **c.** Ne, P, Br **d.** Sb, Bi

51. b; Nitrogen and phosphorus are in the same group (Group 5A).

52. Fluorine has a smaller atomic radius than oxygen because fluorine has a larger nuclear charge. Fluorine has a smaller radius than chlorine because it has eight fewer electrons.

53. Nonmetals; The trend is for ionization energy to increase from left to right across a period.

54. **a.** Ca^{2+} **b.** P^{3-} **c.** C^{u+}

55. 170 pm

56. **a.** H, Li, Na, K, Rb, Cs, Fr **b.** O, S, Se, Te, Po
c. Zn, Cd, Hg, Uub

57. An element's electron configuration determines its location (group) in the periodic table.

58. c

59. First ionization energy increases across a period.

60. It is relatively easy to remove two electrons from magnesium; it is much more difficult to remove a third electron. It is relatively easy to remove three electrons from aluminum; it is much more difficult to remove a fourth electron.

61. **a.** The atomic radius increases from top to bottom within the group.
b. Cations are smaller than their corresponding atoms. The attraction between the nucleus and any remaining electron is greater. There is one fewer occupied energy level.

62. **a.** cations
b. anions
c. cations
d. cations
e. anions
f. cations
g. anions
h. cations

ASSESSMENT

Evaluate

Answers

THINK CRITICALLY

63. Yes, 117; 1 through 116 are known.

64. **a.** Electronegativity increases as first ionization energy increases.
b. Both properties depend on the attraction between the nucleus and electrons in the highest occupied energy level. Across a period, the nuclear charge increases, but the shielding effect is constant.

65. **a.** The electrons in calcium are removed from the same energy level. In potassium, the second electron is removed from a lower energy level.
b. Because cesium has a larger atomic radius than lithium, the nuclear charge in a cesium atom has a smaller effect on the electrons in the highest occupied energy level.
c. The third electron removed from a magnesium atom is in a lower energy level.

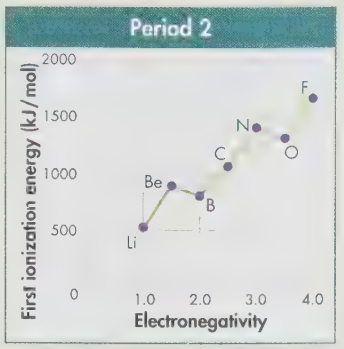
66. Zinc has a greater nuclear charge (more protons) than calcium.

67. **(a)** is Ca, **(b)** is Ca2+, **(c)** is Mg2+. Cations are always smaller than the corresponding atoms, and ionic size generally increases from top to bottom within a group.

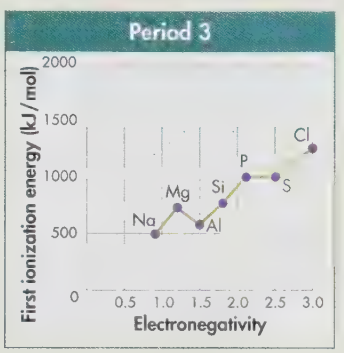
68. **a.** $1s^2 2s^2 2p^6 3s^2 3p^6 3d^{10} 4s^2 4p^6$
b. $1s^2 2s^2 2p^6$
c. $1s^2 2s^2 2p^6$
d. $1s^2 2s^2 2p^6$

69. **a.** francium
b. scandium

70. Because the nuclear charge increases from left to right across a period and the shielding effect stays the same, it is more difficult to remove an electron.



71. Density is equal to mass/volume. For this series of elements, the atomic mass increases, and the atomic size (proportional to volume) decreases. So, the density of these elements must increase going from potassium to chromium.

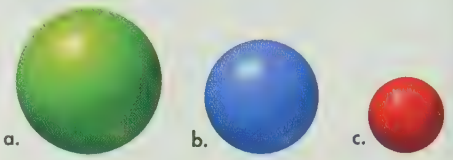


72. Cations are smaller than the corresponding atoms because the attraction between the remaining electrons and the nucleus is increased. Anions are larger than the corresponding atoms because the attraction for any one electron decreases.

Think Critically

63. Predict Do you think there are more elements left to discover? If so, what is the lowest atomic number a new element could have? Explain.

64. Interpret Graphs The graphs show the relationship between the electronegativities and first ionization energies for Period 2 and Period 3 elements.

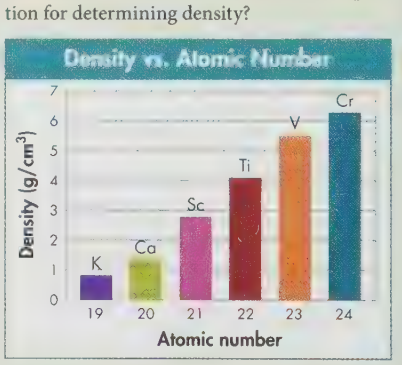


a. Based on data for these two periods, what is the general trend between these two values?
b. Use nuclear charge and shielding effect to explain this trend.

***65. Explain** Give a reason for each of the following comparisons:
a. Calcium has a smaller second ionization energy than does potassium.
b. Lithium has a larger first ionization energy than does cesium.
c. Magnesium has a larger third ionization energy than does aluminum.

***66. Explain** Why does it take more energy to remove a 4*s* electron from zinc than from calcium?

67. Sequence The following spheres represent Ca, Ca^{2+}, and Mg^{2+}. Which one is which? Explain your reasoning.



***68. Apply Concepts** Write the electron configurations of the following ions:
a. the liquid in Group 7A with a 1− charge
b. the metalloid in Period 3 with a 4+ charge
c. the gas in Group 6A with a 2− charge
d. the alkali earth metal in Period 3 with a 2+ charge

69. Interpret Diagrams Use the periodic table and Figure 6.13 to identify the following elements:
a. has its outermost electron in $7s^1$
b. contains only one electron in a *d* orbital

70. Make Generalizations Why is the first ionization energy of a nonmetal much higher than that of an alkali metal?

71. Infer The bar graph shows the densities for the first six elements in Period 4. The density increases across this period from potassium to chromium. Use trends in the periodic table to explain this behavior. *Hint:* What is the equation for determining density?

72. Explain Why are cations smaller and anions larger than the corresponding atoms?

Enrichment

73. Analyze Data Make a graph of atomic mass versus atomic number. Choose eleven points (atomic numbers 1, 10, 20, and so forth up to atomic number 100) to make your graph. Use the graph to describe the relationship between atomic mass and atomic number. Is there a 1:1 correlation between atomic mass and atomic number? Explain.

74. Compare and Contrast The Mg^{2+} and Na^{+} ions each have ten electrons. Which ion would you expect to have the smaller radius? Why?

***75. Predict** Electron affinity is a measure of an atom's ability to gain electrons. Predict the trend for electron affinity across a period. Explain your answer.

76. Explain The ions S^{2-}, Cl^{-}, K^{+}, Ca^{2+}, and Sc^{3+} have the same total number of electrons as the noble gas argon. How would you expect the radii of these ions to vary? Would you expect to see the same variation in the series O^{2-}, F^{-}, Na^{+}, Mg^{2+}, and Al^{3+}, in which each ion has the same total number of electrons as the noble gas neon? Explain your answer.

77. Graph The ionization energies for the removal of the first six electrons in carbon are, starting with the first electron, 1086 kJ/mol, 2352 kJ/mol, 4619 kJ/mol, 6220 kJ/mol, 37,820 kJ/mol, and 47,260 kJ/mol.

- **a.** Use these data to construct a graph of ionization energy versus ionization number. *Note*: The ionization number indicates which electron is lost.
- **b.** Between which two ionization numbers does the ionization energy have the largest increase? Why is this behavior predictable?

***78. Infer** Atoms and ions with the same number of electrons are described as *isoelectronic*.

- **a.** Write the symbol for a cation and an anion that are isoelectronic with krypton.
- **b.** Is it possible for a cation to be isoelectronic with an anion in the same period? Explain.

79. Predict Estimate the atomic radius of praseodymium based on the following data for atomic radii of neighboring elements: La (187.9 pm), Ce (183.2 pm), Nd (182.1 pm), and Pm (181.1 pm). Compare your prediction to the value given in a chemistry handbook.

Write About Science

80. Explain Why does the size of an atom tend to increase from top to bottom within a group? Why does the size of an atom tend to decrease from left to right across a period?

81. Connect to the BIG IDEA The ion Zn^{2+} is important in several biological processes. One process depends on Zn^{2+} temporarily binding to a molecule in red blood cells. When Zn^{2+} is absent, Cd^{2+} can bind to the molecule. However, Cd^{2+} binds more strongly and adversely affects the process. The differences in ionic size is one important cause of the difference in biological activity. How would you expect Hg^{2+} to affect this process? Why?

CHEMYSTERY

Made in the USA

Several of the "unnatural" elements were in fact "made in the USA." For example, elements with atomic numbers 94 through 102 were first artificially prepared in California. Three of these elements have names to prove it—americium, berkelium, and californium. Elements such as these are labeled on the periodic table as "Not found in nature" in this book and as "Artificially prepared" in some others.

Most of the artificially prepared elements are actinides or transactinides. Each of these elements has an unstable nucleus. As a result, these elements undergo radioactive decay, which means their nuclei spontaneously break down into smaller parts in the attempt to gain stability.

82. Infer The elements with atomic numbers 99, 101, 104, and 107 were named to honor past influential scientists. Identify the scientist that each element is meant to honor.

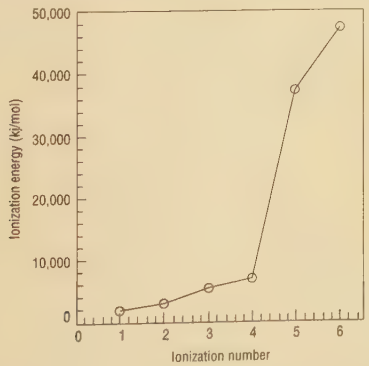
83. Connect to the BIG IDEA Many smoke detectors use the artificially prepared element americium. For a challenge, write the electron configuration of americium.

ASSESSMENT

CHEMYSTERY **SUMMARIZE** After students have read through the CHEMystery, call on volunteers to summarize how the "unnatural" elements compare with other elements in the periodic table. Explain that many of these elements exist only momentarily once synthesized because their nuclei are so unstable. **Ask** How could the periodic table help scientists realize that they might be able to synthesize these elements? *(They would know that elements with certain numbers of protons were not yet identified.)*

Explain to students that although some elements are described as not found in nature on Earth, it is likely that many or all of them are found in nature somewhere in the universe. Convey that other elements, unidentified and with higher numbers of protons, may also exist, but conditions on Earth prevent the elements from occurring naturally on this planet.

ENRCHMENT



73. There is not a 1:1 correspondence. Explanations will vary.

74. Mg^{2+} is smaller because it has more protons; its attraction for electrons is greater.

75. Electron affinity increases (becomes more negative) from left to right across a period because the nuclear charge increases and the shielding effect is constant.

76. The ionic radii decrease from S^{2-} to Sc^{3+}. The number of electrons and the shielding effect do not change, but the number of protons increases from left to right in this series. So, the ionic size decreases. The same is true for the series O^{2-} to Al^{3+}.

77. a.

b. The largest increase is between numbers 4 and 5 because carbon easily loses the first four electrons from the second energy level. The fifth electron is removed from the first energy level.

78. a. Possible cations are Rb^{+} and Sr^{2+}; possible anions are Br^{-}, Se^{2-}, and As^{3-}.

b. No, a cation is isoelectronic with the noble gas in the preceding period, and an anion is isoelectronic with the noble gas in the same period.

79. The atomic radius is likely between 182.1 pm (the atomic radius of Nd) and 183.2 pm (the atomic radius of Ce) because praseodymium is between these two elements in the periodic table. The value from the Handbook of Chemistry and Physics is 182.8 pm.

WRITE ABOUT SCIENCE

80. From top to bottom within a group, the effective nuclear charge remains nearly constant and the principal quantum number increases. From left to right in a period, the principal quantum number remains constant, but the effective nuclear charge increases.

81. From their positions in the periodic table, the three ions most likely have ionic sizes that increase going from Zn^{2+} to Cd^{2+} to Hg^{2+}. Since the increase in size from Zn^{2+} to Cd^{2+} adversely affects the process, it follows that a further increase in size could also adversely affect the process. The toxicity of mercury in biological systems is well known.

CUMULATIVE

82. 99: einsteinium (after Albert Einstein); 101: mendelevium (after Dimitri Mendeleev); 104: rutherfordium (after Ernest Rutherford); 107: bohrium (after Niels Bohr)

83. $1s^2 2s^2 2p^6 3s^2 3p^6 3d^{10} 4s^2 4p^6 4d^{10} 4f^{14} 5s^2 5p^6 5d^{10} 5f^7 6s^2 6p^6 7s^2$

Evaluate

Answers

CUMULATIVE REVIEW

84. Answers will vary but are likely to mention the scientific method.

85. **a.** physical change
b. chemical change
c. physical change
d. chemical change

86. Use a magnet; iron beads are attracted to magnet, copper beads are not. Use tweezers and a magnifying glass; iron beads are silvery black, copper beads are dull red.

87. 4

88. **a.** 3
b. 8, the tenths place

89. The density of the cube is 0.984 g/cm³. The cube will float because its density is less than that of water.

90. **a.** 2.24×10^{-9} m
b. 8.13×10^{-2} m
c. 7.4×10^{-12} m
d. 9.37×10^{-3} m

91. 5.2%

92. 5.2×10^3 g

93. The density of the olive is 1.05 g/cm³. The olive will sink because its density is greater than that of water.

94. 173

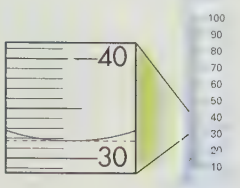
95. The density of sulfur does not vary with mass. The density is constant.

96. 2.57×10^2 mL

97. 4.54 g/cm³

98. **a.** 48
b. 44
c. 114
d. 110

Cumulative Review



84. Explain why science today depends less on chance discoveries than it did in the past.

***85.** Identify each process as a chemical change or a physical change.
a. melting of iron
b. lighting a match
c. grinding corn
d. souring of milk

86. Describe at least two methods to separate a mixture of small copper and iron beads.

87. In the United States, a typical can of cola holds 355 mL. How many 2.00-L bottles could be filled from a 24-can case of cola?

88. The volume of the liquid in the graduated cylinder is reported as 31.8 mL.
a. How many significant figures are there in the measurement?
b. In which digit is there uncertainty?

89. A cube of plastic 1.20×10^{-5} km on a side has a mass of 1.70 g. Show by calculation whether this plastic cube will sink or float in pure water.

***90.** Convert the measurements to meters. Express your answers in scientific notation.
a. 2.24 nm
b. 8.13 cm
c. 7.4 pm
d. 9.37 mm

91. An apprentice jeweler determines the density of a sample of pure gold to be 20.3 g/cm³. The accepted value is 19.3 g/cm³. What is the percent error of the jeweler's density measurement?

92. What is the mass of 7.7 L of gasoline at 20°C? Assume the density of gasoline to be 0.68 g/cm³.

***93.** A black olive containing its seed has a mass of 4.5 g and a volume of 4.3 cm³. Will the olive sink or float on water?

94. The distance from the sun to Earth is 1.50×10^8 km. The speed of light is 3.00×10^8 m/s. How many round trips between Earth and the sun could a beam of light make in one day?

95. The table shows how the volume of sulfur varies with mass. How does the density of sulfur vary with mass?

Mass of Sulfur vs. Volume of Sulfur

Mass of sulfur (g)	Volume of sulfur (cm³)
23.5	11.4
60.8	29.2
115	55.5
168	81.1

96. Calculate the volume of acetone with the same mass as 15.0 mL of mercury. The density of mercury is 13.59 g/mL. The density of acetone is 0.792 g/mL.

97. A rectangular container has inside dimensions of 15.2 cm by 22.9 cm and is about 1 meter tall. Water is poured into the container to a height of 55.0 cm. When a jagged rock with a mass of 5.21 kg is placed in the container, it sinks to the bottom. The water level rises to 58.3 cm and completely covers the rock. What is the density of the rock?

***98.** How many neutrons does an atom of each isotope contain?
a. $^{84}_{36}Kr$
b. $^{79}_{35}Br$
c. $^{190}_{76}Os$
d. $^{185}_{75}Re$

99. Name the element and calculate the number of requested subatomic particles in each isotope.
a. neutrons in $^{109}_{47}Ag$
b. protons in $^{118}_{50}Sn$
c. electrons in $^{96}_{42}Mo$
d. electrons in $^{45}_{21}Sc$

***100.** How many filled *p* orbitals do atoms of these elements contain?
a. carbon
b. phosphorus
c. oxygen
d. nitrogen

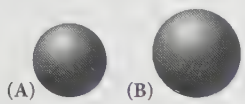
99. **a.** silver, 62 neutrons
b. tin, 50 protons
c. molybdenum, 42 electrons
d. scandium, 21 electrons

100. **a.** none
b. one, 2*p*
c. none
d. none

Standardized Test Prep for Indiana

Standard: C.2.5



Select the choice that best answers each question or completes each statement.

1. Which of the following properties increases as you move across a period from left to right?
   I. electronegativity
   II. ionization energy
   III. atomic radius
   (A) I and II only **(C)** II and III only
   (B) I and III only **(D)** I, II, and III

2. List the symbols for sodium, sulfur, and cesium in order of increasing atomic radii.
   (A) Na, S, Cs **(C)** S, Na, Cs
   (B) Cs, Na, S **(D)** Cs, S, Na

3. The electron configuration for an element in the halogen group should always end with
   (A) ns^2np^6. **(C)** ns^2np^4.
   (B) ns^2np^5. **(D)** ns^2np^2.

Use the spheres to answer Questions 4 and 5.

4. If the spheres represent a potassium atom and a potassium ion, which best represents the ion?

5. If the spheres represent an atom and an anion of the same element, which sphere represents the atom and which represents the anion?

Tips for Success

Interpreting Data Tables Tables can present a large amount of data in a small space. Before you try to answer questions based on a table, look at the table. Read the title, if there is one, and the column headings. Then read the questions. As you read each question, decide which data you will need to use to answer the question.

Use the data table to answer Questions 6–8.

Alkali metal	Atomic radius (pm)	First ionization energy (kJ/mol)	Electronegativity value
Li	152	520	1.0
Na	186	495.8	0.9
K	227	418.8	0.8
Rb	244	250	0.8
Cs	262	210	0.7

6. If you plot atomic radius versus first ionization energy, would the graph reveal a direct or inverse relationship?

7. If you plot atomic radius versus electronegativity, would the graph reveal a direct or inverse relationship?

8. If you plot first ionization energy versus electronegativity, would the graph reveal a direct or inverse relationship?

For each question there are two statements. Decide whether each statement is true or false. Then decide whether Statement II is a correct explanation for Statement I.

	Statement I		Statement II
9.	Electronegativity values are higher for metals than for nonmetals.	BECAUSE	Atoms of nonmetals are among the largest atoms.
10.	A calcium atom is larger than a calcium ion.	BECAUSE	Ions are always larger than the atoms from which they are formed.
11.	The element hydrogen is a metal.	BECAUSE	Hydrogen is on the left in the periodic table.
12.	Among all the elements in a period, the noble gas always has the smallest ionization energy.	BECAUSE	Within any period, atomic radii tend to decrease moving from right to left.

Materials List

For the Student

Small-Scale Lab, p 200
- reaction surface
- micropipettes or droppers
- chemicals: NaCl, $MgSO_4$, $AlCl_3$, $FeCl_3$, $CaCl_2$, $NiSO_4$, $CuSO_4$, $ZnCl_2$, $AgNO_3$, NaOH

Quick Lab, p 207
- 3D-cell batteries
- masking tape
- 2 30-cm lengths of bell wire with ends scraped bare
- clear plastic cup
- distilled water
- tap water
- vinegar
- table sugar
- table salt
- baking soda
- conductivity probe (optional)

For the Teacher

Teacher Demo, p 195
- plastic egg
- 11 marbles

Class Activity, p 203
- tap water samples
- 10-mL graduated cylinder
- potassium thiocyanate solution
- dilute ethanoic acid
- sodium oxalate solution
- dropper

Class Activity, p 204
- crystals of ionic compounds
- watch glasses
- magnifying glasses

Teacher Demo, p 210
- copper metal or alloy
- copper-containing ionic compound

Teacher Demo, p 211
- foam balls of different sizes and colors
- toothpicks

Mexico's Cave of Crystals contains giant gypsum crystals. Gypsum crystals are composed of the ionic compound calcium sulfate ($CaSO_4$) and water.

What's Online

CHEM TUTOR Students access a guided, step-by-step tutorial for predicting formulas of ionic compounds.

PROBLEM SETS Students can practice key problem-solving skills in an online problem set.

MATH HELP Identify the students that struggle with math by assigning an online math skills diagnostic test. These students can then improve and practice math skills using the MathXL tutorial system.

VIRTUAL LAB Students go on an animated virtual lab tour in which ion electron configurations are studied in a simulated laboratory environment.

KINETIC ART Student watch animations of selected figures from the chapter followed by questions to check for understanding.

CONCEPTS IN ACTION Students watch an overview of a key chapter concept using real-world contexts and concrete examples and analogies. Each activity includes an interactive animation followed by analysis questions.

IN ACADEMIC STANDARDS for SCIENCE

Standard 3: Bonding and Molecular Structure

C.3.1 Describe, compare, and contrast the characteristics of the interactions between atoms in ionic and covalent compounds.

C.3.2 Compare and contrast how ionic and covalent compounds form.

C.3.3 Based on the strength of molecular and atomic attractions, explain the physical properties of substances, such as melting and boiling points, electrical and thermal conductivity, and crystal structure.

Also covered C.2.6

Focus on ELL

1 CONTENT AND LANGUAGE Write *ionic, metallic,* and *bonding* on the board. Lead students in discussing the root word for each term.

BEGINNING: LOW/HIGH Visually demonstrate each word. Model an *ion* by drawing an atom and show it gaining or losing an electron. Identify metal objects in the classroom. Demonstrate a bond as an attractive force by having two people grasp hands.

INTERMEDIATE:

LOW Ask simple questions students can answer with either *ion, metal,* or *bond.* For example, point to a metal object and ask what it is made from.

HIGH Lead students in reviewing ions and metals. Encourage them to use the terms *ion, metal,* and *bond* in the discussion.

ADVANCED: LOW/HIGH Have students read the lesson titles and the essential questions. Ask questions to extend the meanings of *ion, metal,* and *bond.* For example, ask what students think an ionic compound is.

BIG IDEA

BONDING AND INTERACTIONS

Essential Questions:

1. *How do ionic compounds form?*
2. *How does metallic bonding affect the properties of metals?*

CHEMYSTERY

It's Not Easy Being Green

While strolling through Central Park in New York City, you come across this statue of the composer Ludwig van Beethoven. It appears to be made of metal, but its surface is green in color and not very shiny. Is the statue's green complexion due to green paint, or something else?

After doing some research, you learn that the statue is made out of bronze, which is a mixture of metals. The statue was never painted. Instead, the exposed surface of the bronze underwent a chemical change, forming a green film over time. You wonder what the film is made of and how it formed. Are the properties of the film different from the bronze beneath it?

▶ Connect to the BIG IDEA As you read about ionic compounds and metals, think about why the statue changed color. Also, think about how the properties of the green film at the surface differ from the metal beneath it.

INDIANA'S ACADEMIC STANDARDS FOR SCIENCE

Atomic Structure and the Periodic Table C.2.6; **Bonding and Molecular Structure** C.3.1, C.3.2, C.3.3. See lessons for details.

Introduce the Chapter

CONNECTION TO ELECTRONS IN ATOMS Students have learned that atoms of different elements have different numbers of electrons. Use the activity to review the idea that atoms can gain or lose electrons.

Activity Have each student use modeling clay to make models of a lithium atom and a fluorine atom. Remind them to use the periodic table to determine the correct number of electrons for their atoms. Have students remove one of the lithium atom's electrons. **Ask** Is the lithium atom still neutral? *(No; it has a positive charge.)* Have students give the electron to the fluorine atom. **Ask** Is the fluorine atom still neutral? *(No; it has a negative charge.)* **Ask** What do you think would happen if the charged atoms were near each other? *(They would be attracted to each other.)*

UbD

Understanding by Design

Students are building toward understanding bonding and interactions by learning about ionic and metallic bonding.

PERFORMANCE GOALS At the end of Chapter 7, students will be able to answer the essential questions by applying their knowledge of ionic and metallic bonding. Students will also be able to predict the formulas of ionic compounds.

ESSENTIAL QUESTIONS Read the essential questions aloud. **Ask** How does the charge of an atom change if it gains or loses an electron? *(It will have a positive charge if it loses an electron. It will have a negative charge if it gains an electron.)* **Ask** Which type of charged atom do you think might bond or be attracted to a negatively charged particle? *(a positively charged atom)*

BIG IDEA Use the photo of giant crystals to help students connect to the concepts they will learn in this chapter. Activate prior knowledge by asking students if they have ever looked at small crystals in rocks or seen large crystals at a museum. Engage students in discussing what might cause crystals like those in the photo to form into geometric shapes. Explain that crystals are the result of the orderly arrangement of atoms. Explain that atoms that have gained or lost electrons have negative or positive charges and atoms with opposite charges can form bonds. If the conditions are suitable, the atoms become ordered and bond together.

CHEMYSTERY Have students read over the CHEMystery. Connect the CHEMystery to the Big Idea of Bonding and Interactions by pointing out that because the statue is surrounded by air, the metal must be interacting with something in the air. Encourage students to predict what this interaction might be that produces the film on the statue. Suggest that they consider whether the film would continue to interact with the air in the same way that the metal does.

LESSON 7.1

Key Objectives

- **7.1.1 DETERMINE** the number of valence electrons in an atom of a representative element.
- **7.1.2 IDENTIFY** the atoms of elements that tend to lose and tend to gain electrons.
- **7.1.3 DESCRIBE** how cations form.
- **7.1.4 EXPLAIN** how anions form.

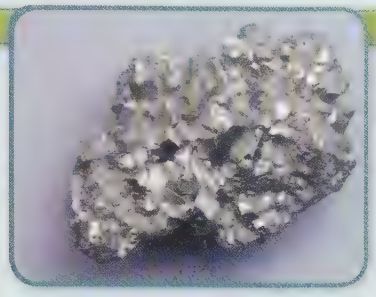
Engage

CHEMISTRY & YOU Have students study the photograph and read the text that opens the lesson. Ask students to suggest reasons for the regular pyrite crystal structure. Do not provide the answer at this point.

Access Prior Knowledge

Have students refer to their copy of the periodic table. **Ask** What does the group number on the periodic table tell you about the electron configuration of a representative element? *(The group number equals the number of electrons in the highest occupied energy level.)* **Ask** *What is formed when electrons are transferred between atoms?* (ions)



IN ACADEMIC STANDARDS for SCIENCE

C.2.6 Use the periodic table and electron configurations to determine an element's number of valence electrons and chemical and physical properties.

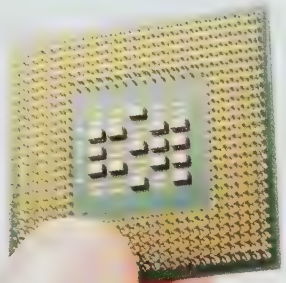
C.3.3 Compare and contrast ionic, covalent network, metallic and polar and non-polar molecular crystals with respect to constituent particles, strength of bonds, melting and boiling points, and conductivity; provide examples of each type.

7.1 Ions

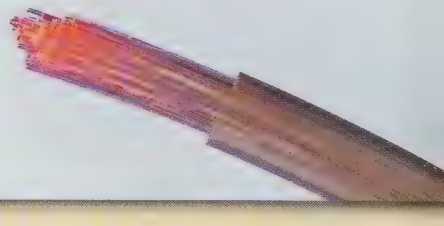
C.2.6 Determine valence electrons and properties; **C.3.3** Chemical bonds and intermolecular attractions

CHEMISTRY & YOU

Q: *What is fools gold?* Pyrite (FeS_2) is often mistaken for gold—hence its nickname, "fool's gold." Pyrite is an example of a crystalline solid. In crystalline solids, the component particles of the substance are arranged in an orderly, repeating fashion. In this chapter, you will learn about crystalline solids, like pyrite, that are composed of ions that are bonded together.



Key Questions



- ***How do you find the number of valence electrons in an atom of a representative element?***
- ***How are cations formed?***
- ***How are anions formed?***

Vocabulary

- valence electron
- electron dot structure
- octet rule
- halide ion

Figure 7.1 Group 4A Elements
Silicon and germanium are Group 4A elements. **a.** Silicon is used in the manufacture of computer chips. **b.** Compounds of germanium are used to make optical fibers.

Valence Electrons

How do you find the number of valence electrons in an atom of a representative element?

Mendeleev used similarities in the properties of elements to organize his periodic table. Scientists later learned that all of the elements within each group of the periodic table react in a similar way because they have the same number of valence electrons. **Valence electrons** are the electrons in the highest occupied energy level of an element's atoms. The number of valence electrons largely determines the chemical properties of an element.

Determining the Number of Valence Electrons The number of valence electrons in an atom of an element is related to the element's group number in the periodic table. **To find the number of valence electrons in an atom of a representative element, simply look at its group number.** For example, atoms of the Group 1A elements (hydrogen, lithium, sodium, and so forth) all have one valence electron, corresponding to the 1 in 1A. Carbon and silicon atoms, in Group 4A, have four valence electrons. Figure 7.1 shows some applications of Group 4A elements. Nitrogen and phosphorus atoms, in Group 5A, have five valence electrons, and oxygen and sulfur atoms, in Group 6A, have six. The noble gases (Group 8A) are the only exceptions to the group-number rule: Atoms of helium have two valence electrons, and atoms of all of the other noble gases have eight valence electrons.

Focus on ELL

1 CONTENT AND LANGUAGE Read the key questions aloud. Have students write each new term on an index card and its definition on the other side. Review the meaning of *representative element*.

2 FRONTLOAD THE LESSON Review pages 170 to 172 with students. Remind them that elements are organized into groups on the periodic table based on the number of electrons in the highest occupied energy level. Explain that these are the *valence electrons* they will study in this lesson.

3 COMPREHENSIBLE INPUT Review the Pauli exclusion principle and Hund's rule before discussing the diagram of sodium ionization on page 196. Remind students that each box represents an orbital in an atom, and that each orbital can contain a maximum of two electrons spinning in opposite directions, asindicated by the two arrows.

Table 7.1

Electron Dot Structures of Some Group A Elements

Period	Group 1A	2A	3A	4A	5A	6A	7A	8A
1	H·							He:
2	Li·	·Be·	·B·	·C·	·N·	:O·	:F·	:Ne:
3	Na·	·Mg·	·Al·	·Si·	·P·	:S·	:Cl·	:Ar:
4	K·	·Ca·	·Ga·	·Ge·	·As·	:Se·	:Br·	:Kr:

Valence electrons are usually the only electrons involved in chemical bonds. Therefore, as a general rule, only the valence electrons are shown in electron dot structures. **Electron dot structures** are diagrams that show valence electrons in the atoms of an element as dots. Table 7.1 shows electron dot structures for atoms of some Group A elements. Notice that all of the elements within a given group (with the exception of helium) have the same number of electron dots in their structures.

The Octet Rule You learned in Chapter 6 that noble gases, such as neon and argon, are nonreactive in chemical reactions. That is, they are stable. In 1916, chemist Gilbert Lewis used this fact to explain why atoms form certain kinds of ions and molecules. He called his explanation the octet rule. The **octet rule** states that in forming compounds, atoms tend to achieve the electron configuration of a noble gas. An octet is a set of eight. Recall that atoms of each of the noble gases (except helium) have eight electrons in their highest occupied energy levels and the general electron configuration of $ns^2 np^6$. The octet rule takes its name from this fact about noble gases.

Atoms of metals tend to lose their valence electrons, leaving a complete octet in the next-lowest energy level. Atoms of some nonmetals tend to gain electrons or to share electrons with another nonmetal atom or atoms to achieve a complete octet. Although exceptions occur, the octet rule applies to atoms in most compounds.

Formation of Cations

How are cations formed?

An atom is electrically neutral because it has equal numbers of protons and electrons. An ion forms when an atom or group of atoms loses or gains electrons. **A positively charged ion, or a cation, is produced when an atom loses one or more valence electrons.** Note that for metals, the name of the cation is the same as the name of the element. For example, a sodium atom (Na) forms a sodium cation (Na^+). Likewise, a calcium atom (Ca) forms a calcium cation (Ca^{2+}). Although their names are the same, metals and their cations have many important chemical differences. Sodium metal, for example, reacts explosively with water. By contrast, sodium cations are quite nonreactive. As you may know, sodium cations are a component of table salt, a compound that is very stable in water.

READING SUPPORT

Build Vocabulary: *Word Origins* *Octet* comes from the Greek word *okto,* meaning "eight." There are eight electrons in the highest occupied energy level of the noble gases, except for helium. ***How do you think the term octet might also be applied to music or poetry?***

Differentiated Instruction

LPR LESS PROFICIENT READERS Lead a class discussion on writing electron dot structures. **Ask** What is the significance of the electrons that are represented by dots? *(They are valence electrons.)* **Ask** How are they placed? *(symmetrically around the atom according to pairing rules)* **Ask** Why are the non-valence electrons not shown? *(Generally, they are not available for chemical bonding.)*

L1 ENGLISH LANGUAGE LEARNERS If possible, pair beginning English speakers with more proficient English speakers that have the same native language. Write the word *stable* on the board and have each pair of students act out the meaning of the word. Have students identify any other content words that the difficult to understand.

L3 ADVANCED STUDENTS Have students show how the atoms of transition elements become stable with pseudo-noble-gas configurations. (These atoms would have to gain or lose too many electrons to achieve a noble-gas electron configuration.) For example, show how Ag, Zn, and Ga lose 1, 2, and 3 electrons, respectively.

Foundations for Reading

BUILD VOCABULARY Have each student choose a halide ion. Then have students create a graphic organizer that shows how a halide ion relates to the other three vocabulary terms.

READING STRATEGY Have students skim the headings, look at the visuals, and read the boldfaced text to preview the section. Then have students decide what content from previous chapters they should review prior to reading this lesson.

Explain

Valence Electrons

USE VISUALS Direct students to Table 7.1. Have students identify the total number of electrons and the number of valence electrons in selected elements from Table 7.1. Reemphasize that the group number equals the number of valence electrons in an atom of a representative element.

APPLY CONCEPTS Explain that the octet rule is helpful for predicting the ionic charges of most representative elements. Caution students that this rule does not apply to all elements, as some elements have several different ionic charges. Point out examples of stable ions formed by the transition elements, such as Mn^{2+} and Mn^{3+}.

Explore

Teacher Demo

PURPOSE To model valence electrons.

MATERIALS plastic egg, 11 marbles

PROCEDURE Hold up a plastic egg containing 10 marbles. State that the egg represents a sodium atom and that the marbles represent the 10 electrons in the $n = 1$ and $n = 2$ energy levels. Explain that these electrons cannot be "removed" without "breaking" the egg. Now hold up one additional marble next to the egg. State that this marble represents the eleventh electron, and occupies the $n = 3$ energy level. This is the valence electron. Explain that if this electron is lost, the resulting atom has an overall 1+ charge.

EXPECTED OUTCOME Students should be able to distinguish valence electrons from nonvalence electrons.

Answers

READING SUPPORT In music, an octet refers to a group of eight performers. In poetry, an octet refers to a group of eight lines of verse.

Explain

Formation of Cations

USE VISUALS Have students examine Figure 7.2 and have a student volunteer read aloud the caption. Display the diagram adjacent to Figure 7.2 on an overhead projector. Point out that the interaction between atoms that produces bonding involves only the outermost electrons of the atoms. Show students that the inner electrons are locked tightly in filled energy levels and do not participate in bonding. Use a colored pen to circle the outermost electron in the sodium atom. Remind students that the outermost electrons are called valence electrons. Use a different colored pen to circle the octet of electrons in the sodium ion's highest occupied energy level. Circle the corresponding octet of electrons in neon to show the similarity in electron configurations. Have students draw a similar diagram for calcium. *(Check student's diagrams.)*

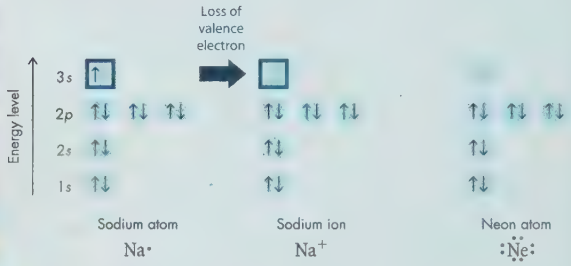
CRITICAL THINKING Explain that the term *isoelectronic* means having equal numbers of electrons or the same electronic configuration. Then, have students determine the accuracy of this statement: All stable ions of representative elements result in electronic configurations that are isoelectronic with noble gases. Explain that a noble gas configuration is not generally possible with elements that would have to gain or lose many electrons.

Misconception Alert

Students tend to confuse the name of the ion that gets the positive charge with the name of the ion that gets the negative charge. To help students remember, post the following in the classroom:
cation: ca + ion (write the 't' as the + sign)
anion: A Negative ION

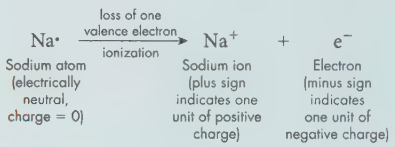
Figure 7.2 Sodium Vapor Lamp
The sodium atoms (Na) in a sodium vapor lamp ionize to form sodium cations (Na^+).
Apply Concepts ***How many electrons are in the highest occupied energy level of Na^+?***

Group 1A Cations The most common cations are those produced by the loss of valence electrons from metal atoms. Most of these atoms have one to three valence electrons, which are easily removed. Sodium (atomic number 11) is in Group 1A of the periodic table. Sodium atoms have a total of eleven electrons, including one valence electron. A sodium atom can lose an electron to become a positively charged sodium ion. Sodium atoms become sodium ions in a sodium vapor lamp, which is shown in Figure 7.2. The sodium ion has an electron configuration that is identical to the noble gas neon.



When forming a compound, a sodium atom loses its one valence electron and is left with an octet (eight electrons) in what is now its highest occupied energy level. The number of protons in the sodium nucleus is still eleven, so the loss of one unit of negative charge produces a cation with a charge of 1+. You can represent the loss of the electron, or ionization, of the sodium atom by drawing the complete electron configuration of the atom and of the ion formed.

$$\text{Na}\ \ 1s^2 2s^2 2p^6 3s^1 \xrightarrow{-e^-} \text{Na}^+\ \ \underbrace{1s^2 2s^2 2p^6}_{\text{octet}}$$



Notice that the electron configuration of the sodium ion ($1s^2 2s^2 2p^6$) is the same as that of a neon atom.

$$\text{Ne}\ \ \underbrace{1s^2 2s^2 2p^6}_{\text{octet}}$$

The diagrams below help illustrate this point.

Both the sodium ion and the neon atom have eight electrons in their valence shells (highest occupied energy levels). Using electron dot structures, you can show the ionization more simply.

UbD Check for Understanding

How do you find the number of valence electrons in an atom of a representative element?

Call out a representative element. Have students hold up their fingers to show you the number of valence electrons in the atom. Repeat with a few more representative elements. Ask students to give you a thumbs up or a thumbs down if they understand that the group number corresponds directly to the number of valence electrons for an atom of a representative element.

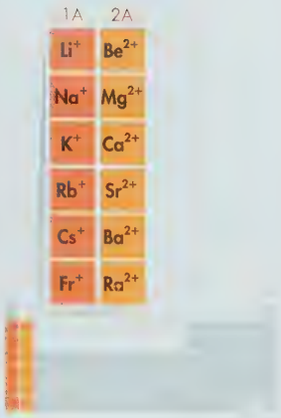
ADJUST INSTRUCTION If students are having difficulty answering the question, make sure they are referring to their periodic table. Direct them to re-read the text in the Valence Electrons section and reassess their understanding by repeating the activity above.

Group 2A Cations Magnesium (atomic number 12) belongs to Group 2A of the periodic table, so magnesium atoms have two valence electrons. A magnesium atom attains the electron configuration of a neon atom by losing both valence electrons and producing a magnesium cation with a charge of 2+.

$$\cdot\mathrm{Mg}\cdot \xrightarrow{\text{loss of two valence electrons}} \mathrm{Mg^{2+}} + 2e^-$$

Magnesium atom (electrically neutral, charge = 0) → Magnesium ion (2+ indicates two units of positive charge) + Electrons (2 in front of e^- indicates two units of negative charge)

Figure 7.3 lists the symbols of the cations formed by metals in Groups 1A and 2A. Cations of Group 1A elements always have a charge of 1+. Cations of Group 2A elements always have a charge of 2+. This consistency can be explained in terms of the loss of valence electrons by metal atoms: The atoms lose the number of electrons necessary to attain the electron configuration of a noble gas.



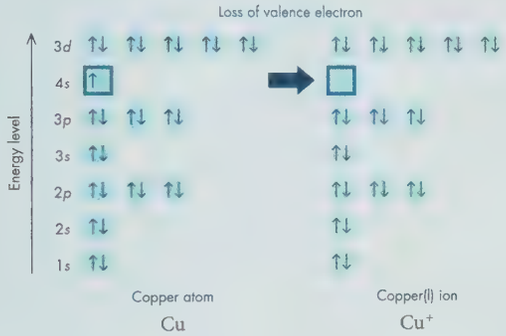


Figure 7.3
Group 1A and 2A Cations
Cations of Group 1A elements have a charge of 1+. Cations of Group 2A elements have a charge of 2+.

Transition Metal Cations The charges of cations of the transition metals may vary. An atom of iron, for example, may lose two valence electrons, forming the Fe^{2+} cation, or three valence electrons, forming the Fe^{3+} cation.

Some ions formed by transition metals do not have noble-gas electron configurations ($ns^2\,np^6$) and are therefore exceptions to the octet rule. Silver, with the electron configuration of $1s^2\,2s^2\,2p^6\,3s^2\,3p^6\,3d^{10}\,4s^2\,4p^6\,4d^{10}\,5s^1$, is an example. To achieve the structure of krypton, which is the preceding noble gas, a silver atom would have to lose eleven electrons. To acquire the electron configuration of xenon, which is the following noble gas, a silver atom would have to gain seven electrons. Ions with charges of three or greater are uncommon. Thus silver does not achieve a noble-gas configuration. However, if a silver atom loses its $5s^1$ electron, forming a positive ion (Ag^+), the configuration that results ($4s^2\,4p^6\,4d^{10}$), with 18 electrons in the highest occupied energy level and all of the orbitals filled, is relatively favorable. Such a configuration is known as a pseudo noble-gas electron configuration. Other elements that behave similarly to silver are found at the right of the transition metal block of the periodic table. A copper atom loses its lone 4*s* electron to form a copper ion (Cu^+) with a pseudo noble-gas electron configuration as illustrated below.

Cations of gold (Au^+), cadmium (Cd^{2+}), and mercury (Hg^{2+}) also have pseudo noble-gas electron configurations.

Differentiated Instruction

L1 SPECIAL NEEDS STUDENTS Ask students to work with a partner to practice drawing electron dot structures for Group A elements. Have one student randomly choose an element and write the symbol for that element on a piece of paper. Have another student fill in the electron dots for this element. Students can check their work by referring to Table 7.1. Make sure students understand that the electron dots represent only valence electrons, not the total number of electrons, and that valence electrons are the only electrons involved in chemical reactivity. Also, reinforce the stable octet dot structures for the noble gases and explain how ions of other elements will react to obtain this configuration.

ELL ENGLISH LANGUAGE LEARNERS Explain to students that when one atom forms an ion, that ion is called a monatomic ion. Explain that the prefix *mon-* or *mono-* means "one."

APPLY CONCEPTS Explain that one method to use to determine the number of valence electrons in an atom is to look at the electron configuration of the atom. Explain that any electron in an atom outside the noble-gas core is called a valence electron. Using diagrams similar to those shown, demonstrate several examples of how various atoms of the representative elements form ions and gain a noble-gas electron configuration. Indicate the noble-gas core and valence electrons in your diagrams.

Explore

Class Activity

PURPOSE Students model the formation of cations using equations.

MATERIALS paper, pencil

PROCEDURE Have students write equations similar to the one shown for Mg in the text, to show the formation of metal cations from metal atoms. Students should show the electron dot structures for the metal atoms and metal cations that are formed. In addition, you may want students to write out the electron configurations for the metal atoms and cations. Check students' work to be sure the correct metal ion is formed.

EXPECTED OUTCOMES Students should be able to use electron dot structures to correctly write equations describing the ionization of metal atoms.

Answers

FIGURE 7.2 8 electrons

Explain

Formation of Anions

INTERPRET DIAGRAMS Direct students' attention to Figure 7.4. Explain that the elements arsenic (As) and tellurium (Te) are metalloids, not nonmetals. However, they form anions that are named according to the same convention as nonmetal anions are named (arsenide, telluride).

START A CONVERSATION Discuss with students how certain elements can form either anions or cations. Have students write the electron configuration of nitrogen ($1s^2 2s^2 2p^3$). **Ask** How can a nitrogen atom form a cation that has the electron configuration of a noble gas? *(It can lose five electrons.)* **Ask** How can a nitrogen atom form an anion that has the electron configuration of a noble gas? *(It can gain three electrons.)* Have them repeat this process for carbon. Explain that atoms that have few electrons to gain or lose to achieve an octet are more likely to form ions. Point out that other atoms are not likely to form ions, and the process they undergo will be studied in Chapter 8.

CHEMISTRY & YOU Diagrams should reflect the following electron configuration: $1s^2 2s^2 2p^6 3s^2 3p^6 3d^6$.

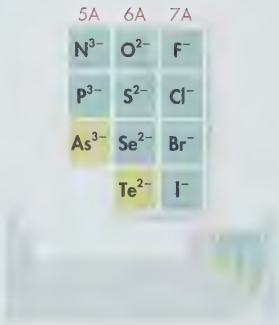

Figure 7.4
Group 5A, 6A, and 7A Anions
Atoms of nonmetals and metalloids form anions by gaining enough valence electrons to attain the electron configuration of the nearest noble gas.
Interpret Diagrams ***To which group of the periodic table do the elements bromine and iodine belong?***

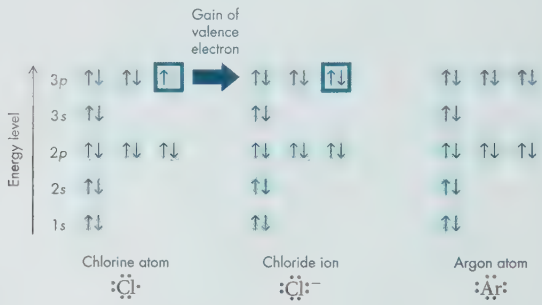
CHEMISTRY & YOU

Q: *Fool's gold is composed of iron(II) cations (Fe^{2+}) and disulfide anions (S_2^{2-}). Write the electron configuration of the Fe^{2+} ion.*

Formation of Anions

How are anions formed?

An anion is an atom or group of atoms with a negative charge. **An anion is produced when an atom gains one or more valence electrons.** Note that the name of an anion of a nonmetallic element is *not* the same as the element name. The name of the anion typically ends in *-ide*. Thus, a chlorine atom (Cl) forms a chloride anion (Cl^-), and an oxygen atom (O) forms an oxide anion (O^{2-}). Figure 7.4 shows the symbols of the anions formed by some elements in Groups 5A, 6A, and 7A.



Atoms of nonmetallic elements attain noble-gas electron configurations more easily by gaining electrons than by losing them because these atoms have relatively full valence shells. For example, chlorine belongs to Group 7A (the halogen family). Atoms of chlorine have seven valence electrons. A gain of one electron gives a chlorine atom an octet and converts a chlorine atom into a chloride ion.

$$Cl\ \ 1s^2 2s^2 2p^6 3s^2 3p^5 \xrightarrow{+e} Cl^-\ \ 1s^2 2s^2 2p^6 \underbrace{3s^2 3p^6}_{\text{octet}}$$

The chloride ion has a single negative charge. Notice that the electron configuration of the chloride ion ($1s^2 2s^2 2p^6 3s^2 3p^6$) is the same as that of an argon atom.

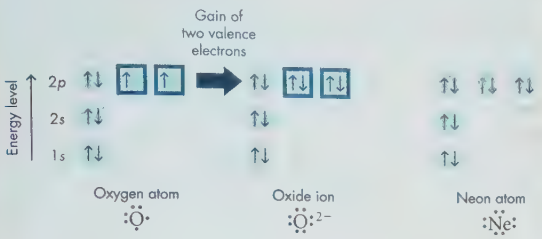
$$Ar\ \ 1s^2 2s^2 2p^6 \underbrace{3s^2 3p^6}_{\text{octet}}$$

Chlorine atoms, therefore, need one more valence electron to achieve the electron configuration of the nearest noble gas. The diagrams below illustrate how both the chloride ion and the argon atom have an octet of electrons in their highest occupied energy levels.

You can use electron dot structures to write an equation showing the formation of a chloride ion from a chlorine atom.

$$:\dot{\underset{\cdot\cdot}{Cl}}\cdot + e^- \xrightarrow{\text{gain of one valence electron}} :\underset{\cdot\cdot}{Cl}:^-$$

Chlorine atom Electron Chloride ion



Professional Development Note

Water Purification

Chlorine gas is often used to purify drinking water. It kills a variety of microorganisms, including those that carry diseases. But chlorine also reacts with organic substances in the water to produce chlorinated compounds such as chloroacetonitrile. Chloroacetonitrile has been shown to cause inflammation of the digestive tract in laboratory animals. As an alternative to chlorine, some countries have begun purifying water with ozone. Ozone kills microorganisms even more effectively than chlorine. About one percent of the water supply in the United States is now purified with ozone. It is estimated that it would cost $6 billion to switch completely to ozone for treating all the drinking water supplies.

The ions produced when atoms of chlorine and other halogens gain electrons are called **halide ions.** All halogen atoms have seven valence electrons and need to gain only one electron to achieve the electron configuration of a noble gas. Thus, all halide ions (F^-, Cl^-, Br^-, and I^-) have a charge of 1−. The seawater in Figure 7.5 contains many different ions, but the anions are mostly chloride ions.

Oxygen is in Group 6A, and an oxygen atom has six valence electrons. An oxygen atom attains the electron configuration of neon by gaining two electrons, as shown in the diagrams below.

The resulting oxide anion (O^{2-}) has a charge of 2−. You can write the equation for the formation of oxide anions by using electron dot structures.

$$:\dot{\underset{\cdot\cdot}{O}}\cdot + 2e^- \longrightarrow :\underset{\cdot\cdot}{\overset{\cdot\cdot}{O}}:^{2-}$$

Table 7.2 lists some common anions that you will be learning about in this book.

Figure 7.5 Ions in Seawater Chloride (Cl^-), sodium (Na^+), magnesium (Mg^{2+}), calcium (Ca^{2+}), and potassium (K^+) ions are abundant in seawater.

Table 7.2
Some Common Anions

Name	Symbol	Charge
Fluoride	F^-	1−
Chloride	Cl^-	1−
Bromide	Br^-	1−
Iodide	I^-	1−
Oxide	O^{2-}	2−
Sulfide	S^{2-}	2−
Nitride	N^{3-}	3−
Phosphide	P^{3-}	3−

7.1 LessonCheck

1. **Explain** How can you determine the number of valence electrons in an atom of a representative element?
2. **Describe** How do cations form?
3. **Describe** How do anions form?
4. **Make Generalizations** Atoms of which elements tend to gain electrons? Atoms of which elements tend to lose electrons?
5. **Apply Concepts** How many valence electrons are in each atom?
   a. potassium
   b. carbon
   c. magnesium
   d. oxygen
6. **Use Models** Draw the electron dot structure for each element in Question 5.
7. **Apply Concepts** How many electrons will each element gain or lose in forming an ion?
   a. calcium
   b. fluorine
   c. aluminum
   d. oxygen
8. **Infer** Identify the charge of the ion formed when
   a. a potassium atom loses one electron.
   b. a zinc atom loses two electrons.
   c. a fluorine atom gains one electron.
9. **Describe** Write the electron configuration of Cd^{2+}.

Lesson Check Answers

1. look up the group number of that element
2. An atom loses valence electrons.
3. An atom gains valence electrons.
4. Atoms of nonmetallic elements tend to gain electrons; atoms of metallic elements tend to lose electrons.
5. **a.** 1 **b.** 4 **c.** 2 **d.** 6
6. **a.** $K\cdot$ **b.** $\cdot\dot{C}\cdot$ **c.** $\cdot Mg\cdot$ **d.** $:\ddot{O}:$
7. **a.** lose 2 **b.** gain 1 **c.** lose 3 **d.** gain 2
8. **a.** potassium cation, K^+ **b.** zinc cation, Zn^{2+} **c.** fluoride anion, F^-
9. Cd^{2+}: $1s^22s^22p^63s^23p^63d^{10}4s^24p^64d^{10}$

Evaluate

Informal Assessment

Have students refer to their copy of the periodic table. To determine the students' knowledge about the formation of elemental anions and cations, have them work in small groups to decide whether the following ions are likely to exist, and why:

- H^- *(yes, isoelectronic with He);*
- H^+ *(yes, but without electrons, there is no comparable noble-gas configuration);*
- Sr^{2+} *(yes, isoelectronic with Kr);*
- Al^{3+} *(yes, isoelectronic with Ne);*
- Xe^- *(no, cannot form ions easily due to stable electron configuration);*
- Zn^{6-} *(no, isoelectronic with Kr but formation would require a gain of too many electrons);*
- Zn^{2+} *(yes, not isoelectronic with a noble gas but has pseudo-noble-gas electron configuration with eighteen electrons filling up the outer occupied energy level: $3s^23p^63d^{10}$)*

Then have students complete the 7.1 Lesson Check.

Reteach

Select groups from the periodic table in random order and ask students to predict the common ions that could be formed from elements of each group. Point out that predicting is fairly easy for groups at the far left or far right of the table, but more difficult for groups in the center of the table, which have partially filled *d* and *f* orbitals. Guide students through the information about forming anions and cations, and then repeat the assessment.

Answers

FIGURE 7.4 Group 7A

Small-Scale Lab

OBJECTIVE After completing this activity, students will be able to write electron configurations for various transition metals.

SKILLS FOCUS Observing, drawing conclusions, designing experiments

PREP TIME 40 minutes

CLASS TIME 40 minutes

MATERIALS small-scale pipettes, solutions

ADVANCE PREPARATION

Solution	Preparation
1.0*M* NaCl	14.6 g in 250 mL
0.2*M* $MgSO_4$	6.0 g in 250 mL
0.2*M* $AlCl_3$	12.1 g in 250 mL
0.1*M* $FeCl_3$	6.8 g in 250 mL 0.1*M* NaCl
0.5*M* $CaCl_2$	14.2 g in 250 mL
0.2*M* $NiSO_4$	2.94 g in 250 mL
0.2*M* $CuSO_4$	12.5 g in 250 mL
0.2*M* $ZnCl_2$	6.8 g in 250 mL
0.05*M* $AgNO_3$	2.1 g in 250 mL
0.5*M* NaOH	20.0 g in 1.0 L

EXPECTED OUTCOME NaCl: colorless, no precipitate; $MgSO_4$, $AlCl_3$, $CaCl_2$, $ZnCl_2$: colorless, white precipitate; $FeCl_3$: yellow, rust-colored precipitate; $NiSO_4$: green, green precipitate; $CuSO_4$: blue, blue precipitate; $AgNO_3$: colorless, brown precipitate

ANALYZE AND CONCLUDE

4. $CuSO_4$, $FeCl_3$, and $NiSO_4$.
5. Cu^{2+}: $1s^2 2s^2 2p^6 3s^2 3p^6 3d^9$
   Ag^+: $1s^2 2s^2 2p^6 3s^2 3p^6 3d^{10} 4s^2 4p^6 4d^{10}$
6. It contains a completely full *d* orbital.
   Zn^{2+}: $1s^2 2s^2 2p^6 3s^2 3p^6 3d^{10}$
7. Cr^{3+} and V^{2+} are colored because their electron configurations have partially filled *d* orbitals. Hg^{2+} and Cd^{2+} are colorless because their configurations contain completely full *d* orbitals.
8. Yes, except the one produced by silver nitrate.

YOU'RE THE CHEMIST

1. Add one drop of Na_2CO_3 to one drop of each solution. The iron, copper, and nickel salts produce colored precipitates.
2. Add one drop of Na_3PO_4 to one drop of each solution. The iron, copper, and nickel salts produce colored precipitates.

Small-Scale Lab

Electron Configurations of Ions

Purpose

To relate the presence of color in an ionic solution as a characteristic of electron configurations

Materials

- reaction surface
- micropipettes or droppers
- chemicals shown in the grid below
- sodium hydroxide (NaOH) solution

Procedure

1. On separate sheets of paper, draw two grids similar to the one below. Make each square 2 cm on each side.
2. Place a reaction surface over one of the grids, and add one drop of each solution in the indicated places. Record the color of each solution on the other grid.
3. A precipitate is a solid that separates upon mixing solutions. Predict which of the metal cations will form colored precipitates upon the addition of NaOH. Add one drop of NaOH to find out. Record your results.

NaCl	$MgSO_4$	$AlCl_3$
$FeCl_3$	$CaCl_2$	$NiSO_4$
$CuSO_4$	$ZnCl_2$	$AgNO_3$

Analyze and Conclude

1. **Draw Conclusions** Transition-metal ions with partially filled *d* orbitals usually have color. Based on your observations, which solutions contain transition-metal ions with partially filled *d* orbitals?
2. **Analyze Data** Write the electron configurations of Cu^{2+} and Ag^+. Is each electron configuration consistent with the color you observed for each cation? Explain.
3. **Infer** What does the color of the solution containing Zn^{2+} ions suggest about its electron configuration? Write the electron configuration of Zn^{2+}.
4. **Predict** Which of the following transition-metal ions do you think have color: Cr^{3+}, Cd^{2+}, Hg^{2+}, V^{2+}? Explain your answers.
5. **Draw Conclusions** Do the colored precipitates all contain transition-metal ions with partially filled *d* orbitals?

You're the Chemist

1. **Design an Experiment** Predict which of the metal cations in this experiment will form colored precipitates upon the addition of sodium carbonate (Na_2CO_3). Design an experiment to find out.
2. **Design an Experiment** Design and carry out an experiment to find out which metal ions form precipitates with sodium phosphate (Na_3PO_4). What color are the precipitates?

Focus on ELL

4 LANGUAGE PRODUCTION Have students work in pairs to complete the lab. Pair students so that more proficient English speaking students can help less proficient English speaking students. Have students work according to their proficiency level.

BEGINNING:

LOW Model this lab and ask students to say the color that each metal produces.

HIGH Provide students with a chart of the solutions and then a column for them to write the color produced.

INTERMEDIATE: LOW/HIGH Have students predict which metals have color. Ask them to orally compare the actual result with their prediction.

ADVANCED: LOW/HIGH Ask students to complete the Analyze and Conclude questions with written responses.

7.2 Ionic Bonds and Ionic Compounds

C.3.1 Interactions between atoms in ionic and covalent compounds; C.3.2 Formation of ionic and covalent compounds; C.3.3 Chemical bonds and intermolecular attractions

CHEMISTRY & YOU

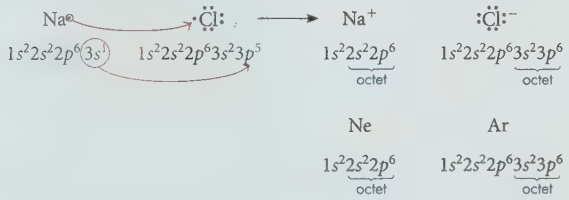
Q: *Where does table salt come from?* Sodium chloride, or table salt, has been used by people for centuries to add flavor to food and for preserving food. In some countries, salt is obtained by the evaporation of seawater. In other countries, salt is mined from rock deposits deep underground. In this lesson, you will learn how cations and anions combine to form stable compounds such as sodium chloride.

Key Questions

- ***What is the electrical charge of an ionic compound?***
- ***What are three properties of ionic compounds?***

Vocabulary

- ionic compound
- ionic bond
- chemical formula
- formula unit
- coordination number



Formation of Ionic Compounds

What is the electrical charge of an ionic compound?

Sodium chloride, or table salt, is an ionic compound consisting of sodium cations and chloride anions. An **ionic compound** is a compound composed of cations and anions. **Although they are composed of ions, ionic compounds are electrically neutral.** The total positive charge of the cations equals the total negative charge of the anions.

Ionic Bonds Anions and cations have opposite charges and attract one another by means of electrostatic forces. The electrostatic forces that hold ions together in ionic compounds are called **ionic bonds.**

Sodium chloride provides a simple example of how ionic bonds are formed. Consider the reaction between a sodium atom and a chlorine atom. The sodium atom has a single valence electron that it can easily lose. (If the sodium atom loses its valence electron, it achieves the stable electron configuration of neon.) The chlorine atom has seven valence electrons and can easily gain one electron. (If the chlorine atom gains a valence electron, it achieves the stable electron configuration of argon.) When sodium and chlorine react to form a compound, the sodium atom transfers its one valence electron to the chlorine atom. Thus, sodium and chlorine atoms combine in a one-to-one ratio, and both ions have stable octets.

Focus on ELL

1 CONTENT AND LANGUAGE Write the vocabulary terms on the board along with their phonetic spellings and pronounce them slowly. Discuss the meaning of each word in each term, and then explain the meaning of the combined term. Have students produce a half-page illustration or example for each vocabulary term.

2 FRONTLOAD THE LESSON Have small groups of students read aloud and discuss the lesson headings and key questions. Then have them write at least one sentence for each page summarizing what they will study on that page.

3 COMPREHENSIBLE INPUT Explain to students that they will study the interaction of ions in this lesson. As a visual analogy, show students two magnets with opposite poles attracting each other. Explain that this attraction is similar to the attraction between oppositely charged ions. Be sure to stress that the attraction between the ions is due to electrical charge, not magnetic force.

LESSON 7.2

Key Objectives

7.2.1 EXPLAIN the electrical charge of an ionic compound.

7.2.2 DESCRIBE three properties of ionic compounds.

Additional Resources

Reading and Study Workbook, Lesson 7.2

Available Online or on Digital Media:

PearsonChem.com

Engage

CHEMISTRY & YOU Have students examine the opening photograph along with Figure 7.7. Discuss how the poisonous elements sodium and chlorine can react to form harmless table salt. **Ask** What characteristics of sodium and chlorine atoms allow them to form a stable compound? *(Sodium atoms can lose an electron easily, and chlorine atoms can accept an electron easily. The resulting ions are attracted to the oppositely charged ions.)* Remind students that NaCl is an example of an ionic compound.

Access Prior Knowledge

Have students review the patterns in Tables 6.1 and 6.2. **Ask** What term is used to describe the ability of an atom of an element to attract electrons? *(electronegativity)*

IN ACADEMIC STANDARDS for SCIENCE

- Develop explanations based on reproducible data and observations gathered during laboratory investigations.

C.3.1 Describe, compare, and contrast the characteristics of the interactions between atoms in ionic and covalent compounds.

C.3.2 Compare and contrast how ionic and covalent compounds form.

Also covered C.3.3.

Foundations for Reading

BUILD VOCABULARY Have students skim the lesson to locate the definition of each vocabulary term. Then have them define each term in their own words.

READING STRATEGY Have students rewrite the headings as how, why, or what questions about ionic compounds. As they read, have them write answers to their questions.

Explain

Formation of Ionic Compounds

APPLY CONCEPTS Explain that the formation of positive ions and negative ions are simultaneous and interdependent processes. Explain that an ionic compound is the result of the transfer of electrons from one set of atoms to another set of atoms. Emphasize that an ionic compound consists entirely of ions. Have students name some substances that they think are ionic compounds. As a class, determine which substances are in fact ionic compounds, and why.

CRITICAL THINKING Direct students' attention to Figure 7.7. **Ask** Why are crystalline ionic compounds generally so rigid and brittle? *(The crystal is rigid because it is held together by a specific three-dimensional array of relatively strong attractive forces between anions and cations, which is accompanied by minmal repulsion of like ions. The crystal is brittle because the attractive interactions are specifically arranged within the crystal structure. If this arrangement is disturbed, as it would be if the crystal were hit with a hammer, repulsion between ions of the same charge can force the crystal to fragment.)*

Figure 7.6 Formation of Aluminum Bromide Aluminum metal and the nonmetal bromine react violently to form the ionic solid aluminum bromide.

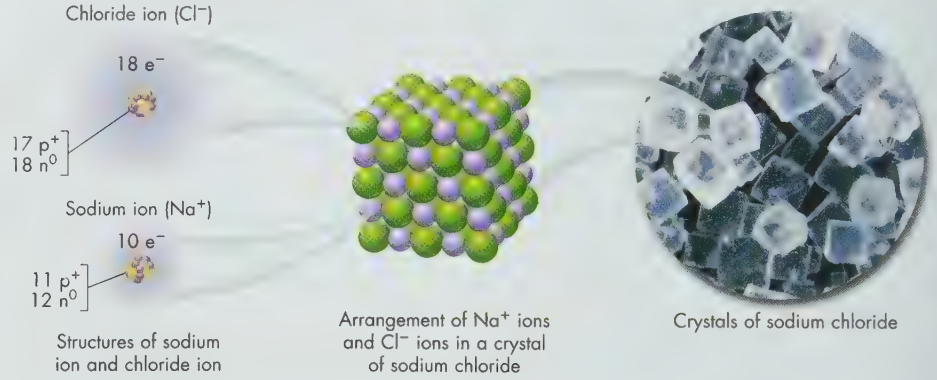

Figure 7.6 shows the reaction of aluminum (Al) and bromine (Br_2) to form the ionic compound aluminum bromide ($AlBr_3$). Each aluminum atom has three valence electrons to lose. Each bromine atom has seven valence electrons and readily gains one additional electron. Therefore, when aluminum and bromine react, three bromine atoms combine with each aluminum atom.

Formula Units The ionic compound sodium chloride is composed of equal numbers of sodium cations (Na^+) and chloride anions (Cl^-). Chemists represent the composition of substances by writing chemical formulas. A **chemical formula** shows the numbers of atoms of each element in the smallest representative unit of a substance. For example, NaCl is the chemical formula for sodium chloride.

Note that the formula NaCl does not represent a single physical unit. As shown in Figure 7.7, the ions in solid sodium chloride are arranged in an orderly pattern. Ionic compounds do not exist as single discrete units, but as collections of positively and negatively charged ions arranged in repeating patterns. Therefore, the chemical formula of an ionic compound refers to a ratio known as a formula unit. A **formula unit** is the lowest whole-number ratio of ions in an ionic compound. For sodium chloride, the lowest whole-number ratio of the ions is 1:1 (one Na^+ ion to each Cl^- ion). Thus, the formula unit for sodium chloride is NaCl. Although ionic charges are used to derive the correct formula, they are not shown when you write the formula unit of the compound.

The ionic compound magnesium chloride contains magnesium cations (Mg^{2+}) and chloride anions (Cl^-). In magnesium chloride, the ratio of magnesium cations to chloride anions is 1:2 (one Mg^{2+} ion to two Cl^- ions). Therefore, the formula unit for magnesium chloride is $MgCl_2$. The compound has twice as many chloride anions (each with a 1− charge) as magnesium cations (each with a 2+ charge), so it is electrically neutral. In aluminum bromide, the ratio of aluminum cations to bromide anions is 1:3 (one Al^{3+} ion to three Br^- ions), so the formula unit is $AlBr_3$. Again, the compound is electrically neutral.

Figure 7.7 Formation of Sodium Chloride Sodium cations and chloride anions form a repeating three-dimensional array in sodium chloride (NaCl).
Infer ***How does the arrangement of ions in a sodium chloride crystal help explain why the compound is so stable?***

UbD Check for Understanding

The Essential Question **How do ionic compounds form?**

Assess students' understanding of the process of ionic bond formation by asking them to complete the following cloze prompt:

Ionic bonds form when one or more _____ is transferred from a _____ to a(n) _____ so that both ions form a _____. *(electrons, cation, anion, stable octet)*

ADJUST INSTRUCTION If students are having difficulty answering this question, have them reread the last paragraph on page 201 and examine the diagram below it. Then provide students another opportunity to complete the prompt.

Sample Problem 7.1

Predicting Formulas of Ionic Compounds

Use electron dot structures to predict the formulas of the ionic compounds formed from the following elements:

a. potassium and oxygen

b. magnesium and nitrogen

1 Analyze **Identify the relevant concepts.** Atoms of metals lose valence electrons when forming an ionic compound. Atoms of nonmetals gain electrons. Enough atoms of each element must be used in the formula so that electrons lost equals electrons gained.

2 Solve **Apply the concepts to this problem.**

Start with the atoms.

a. $K\cdot$ and $\cdot\ddot{O}:$

In order to have a completely filled valence shell, the oxygen atom must gain two electrons. These electrons come from two potassium atoms, each of which loses one electron.

$$2\,K\cdot + \cdot\ddot{O}: \longrightarrow 2\,K^+ \; :\ddot{O}:^{2-}$$

Express the electron dot structure as a formula.

The formula of the compound formed is K_2O (potassium oxide).

Start with the atoms.

b. $\dot{M}g$ and $\cdot\dot{N}:$

Each nitrogen atom needs three electrons to have an octet, but each magnesium atom can lose only two electrons. Three magnesium atoms are needed for every two nitrogen atoms.

$$3\,\dot{M}g + 2\,\cdot\dot{N}: \longrightarrow 3\,Mg^{2+} \; 2\,:\dot{N}:^{3-}$$

Express the electron dot structure as a formula.

The formula of the compound formed is Mg_3N_2 (magnesium nitride).

10. Use electron dot structures to determine formulas of the ionic compounds formed when

a. potassium reacts with iodine.

b. aluminum reacts with oxygen.

11. What is the formula of the ionic compound composed of calcium cations and chloride anions?

Professional Development Note

Water Hardness

Water hardness varies with location and source, and is primarily a result of a high calcium and magnesium ion content, although other metal ions contribute to the problem. The United States Geological Survey (USGS) considers water to be hard if it contains greater than 60 mg/L of calcium carbonate. People who live in areas with hard water often see this problem manifested as a build-up of limescale on tubs, sinks, faucets, and other surfaces frequently exposed to water.

Generally, water from groundwater sources is harder than water from surface sources. In the United States, most northeastern, southern, and northwestern states have predominantly soft water. Generally, hard water of varying degrees is found in the southwestern and midwestern states.

Sample Practice Problem

Use electron dot structures to determine chemical formulas for the ionic compounds formed when the following elements combine:

a. magnesium and chlorine ($MgCl_2$)

b. aluminum and sulfur (Al_2S_3)

c. calcium and iodine (CaI_2)

Explore

Properties of Ionic Compounds

Class Activity

PURPOSE Students detect the presence of ions in water samples.

MATERIALS tap water samples, 10-mL graduated cylinder, potassium thiocyanate solution, dilute ethanoic acid, sodium oxalate solution, dropper

PROCEDURE Have students bring water samples from home to test for ions associated with water hardness. Test 2-mL samples as follows. Add three drops of potassium thiocyanate (KSCN) to the first sample. Add three drops of dilute ethanoic acid, CH_3COOH, and three drops of sodium oxalate, $Na_2C_2O_4$, to the second sample. Mix well.

EXPECTED OUTCOME A red color from the iron(III) thiocyanate ion, $Fe(SCN)^{2+}$, indicates the presence of Fe^{3+} ions. A white precipitate of calcium oxalate, CaC_2O_4, indicates the presence of Ca^{2+} ions.

Answers

FIGURE 7.7 Each ion is surrounded by ions of opposite charge.

10. **a.** The formula is KI.

b. The formula is Al_2O_3.

11. $CaCl_2$

Explore

Class Activity

PURPOSE Students observe different types of crystals.

MATERIALS crystals of ionic compounds, watch glasses, magnifying glasses

SAFETY Use only nontoxic crystals. Remind students to not touch the crystals.

PROCEDURE Pass around watch glasses with crystals of ionic compounds. Have the students examine the crystals with magnifying glasses and write down their observations. Make a list of these observations and then discuss them in terms of the underlying ionic lattice structures.

EXPECTED OUTCOME Students should observe the geometries of different crystal structures.

CHEMISTRY & YOU *Sample answer:* I would expect NaCl in underground rock deposits to exist as a crystalline solid because NaCl is an ionic compound.

Extend

USE VISUALS Point out the formulas for barite and aragonite in Figure 7.8. Note that those compounds contain anions that are polyatomic ions, which means that they contain more than one type of atom. Tell students that they will learn more about polyatomic ions in Chapter 8. (If students ask about the formulas with multiple cations, explain that those formulas represent complex minerals.)

CHEMISTRY & YOU

Q: *Would you expect to find sodium chloride in underground rock deposits as a solid, liquid, or gas? Explain.*

Properties of Ionic Compounds

What are three properties of ionic compounds?

Figure 7.8 shows the striking beauty of the crystals of some ionic compounds. **Most ionic compounds are crystalline solids at room temperature.** The component ions in such crystals are arranged in repeating three-dimensional patterns. In solid sodium chloride, each sodium ion is surrounded by six chloride ions, and each chloride ion is surrounded by six sodium ions. In this arrangement, each ion is attracted strongly to each of its neighbors, and repulsions are minimized. The large attractive forces result in a very stable structure. This stability is reflected in the fact that NaCl has a melting point of about 800°C. **Ionic compounds generally have high melting points.**

Figure 7.8 Crystalline Solids
The beauty of crystalline solids, such as these, comes from the orderly arrangement of their component ions.

Go online to learn about properties of ionic crystals

Differentiated Instruction

ELL ENGLISH LANGUAGE LEARNERS Encourage students to look up and define terms used to describe ionic compounds. Students should define terms such as *crystal* and *formula unit* in English and their native language.

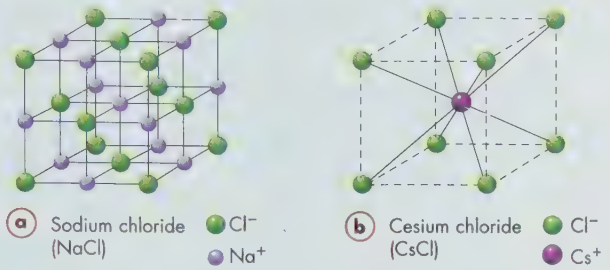
L1 STRUGGLING STUDENTS Students may have difficulty visualizing the ions that represent the coordination number for the example crystals in Figures 7.9 and 7.10. Provide students with copies of both figures, and project the figures on the board. Select a Na^+ ion in NaCl and number the Cl^- ions around it. Then, select a Cl^- ion and number the Na^+ ions around it. Repeat with CaCl and TiO_2, having students direct you as you number each ion.

L3 ADVANCED STUDENTS Have students research how minerals are classified. Suggest that their written reports include information about the physical properties of minerals and how these properties are used in mineral identification. Encourage students to include drawings, photos, or samples of minerals.

The **coordination number** of an ion is the number of ions of opposite charge that surround the ion in a crystal. Figure 7.9a shows the three-dimensional arrangement of ions in NaCl. The coordination number of Na^+ is 6 because each Na^+ ion is surrounded by six Cl^- ions. The coordination number of Cl^- is also 6 because each Cl^- ion is surrounded by six Na^+ ions. Cesium chloride (CsCl) has a formula unit that is similar to that of NaCl. As Figure 7.9b illustrates, both compounds have cubic crystals, but their internal crystal structures are different. Each Cs^+ ion is surrounded by eight Cl^- ions, and each Cl^- ion is surrounded by eight Cs^+ ions. Therefore, each anion and each cation in cesium chloride has a coordination number of 8.

Figure 7.10 shows the crystalline form of titanium dioxide (TiO_2), also known as rutile. In this compound, the coordination number for the cation (Ti^{4+}) is 6. Each Ti^{4+} ion is surrounded by six O^{2-} ions. The coordination number of the anion (O^{2-}) is 3. Each O^{2-} ion is surrounded by three Ti^{4+} ions.

See crystal structures of ionic compounds *online.*



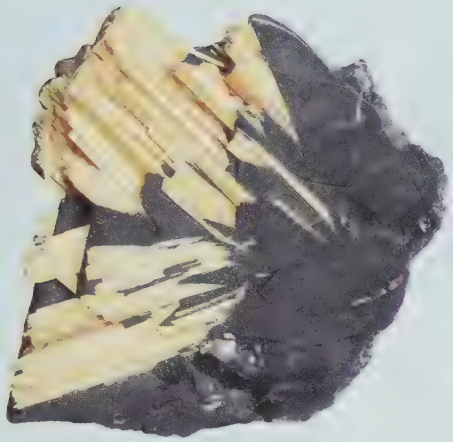


Figure 7.9 Coordination Numbers
Sodium chloride and cesium chloride form cubic crystals. **a.** In NaCl, each ion has a coordination number of 6. **b.** In CsCl, each ion has a coordination number of 8.

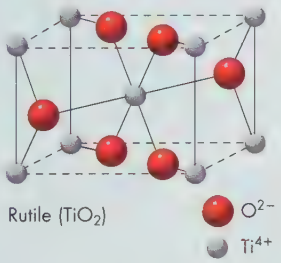

Figure 7.10 Rutile
Titanium dioxide, or rutile, forms tetragonal crystals. In TiO_2, each Ti^{4+} ion has a coordination number of 6, while each O^{2-} ion has a coordination number of 3.

UbD Check for Understanding

BIG IDEA Bonding and Interactions To assess students' knowledge about ionic bonds and ionic compounds, have students write one-minute responses to the following questions:

- Given what you have learned so far, write or illustrate your own definition of an ionic bond. *(an electical attraction between ions of opposite charge)*
- Explain why crystals of different ionic compounds have different shapes. *(The shapes reflect different geometric arrangements of anions and cations.)*

ADJUST INSTRUCTION If students demonstrate difficulty answering the second question, review Figure 7.10 and discuss how each crystal's shape is determined by the coordination number of an ion. Then, encourage them to go online and watch the Concepts in Action feature about properties of ionic crystals.

Explain

CRITICAL THINKING Point out that the rusting of iron is the production of iron oxide from iron metal and oxygen gas. Point out that Fe^{3+} is a stable cation of Fe. **Ask** What is the stable anion of oxygen? *(O^{2-})* **Ask** What compound is formed from these two ions? *(The compound formed from these ions is iron(III) oxide, or Fe_2O_3.)*

Explore

Class Activity

PURPOSE Students investigate properties of different classes of ionic compounds.

MATERIALS library or Internet access

PROCEDURE Divide the class into groups. Have each group choose a different class of ionic compounds to research and write about. For example, one group could work with oxides while another group works with sulfides. Initially, each student should work alone to discover information such as where the compounds occur in nature, how they are produced, their physical and chemical properties, and any important uses. Finally, students in each group can pool their information to prepare a class display or report.

EXPECTED OUTCOMES Students will discover that different classes of ionic compounds share some properties with other ionic compounds and have some unique properties.

Explore

QuickLab

OBJECTIVE After completing this activity, students will be able to show that ions in solution conduct an electric current.

Misconception Alert

Students may think that the solutions contain only one ion. Clarify that each solution contains both cations and anions.

SKILLS FOCUS Observing, experimenting, concluding

PREP TIME 20 minutes

CLASS TIME 30 minutes

MATERIALS D-cell batteries, masking tape, 30-cm lengths of bell wire with ends scraped bare, clear plastic cups, distilled water, tap water, vinegar, sucrose, sodium chloride, baking soda, conductivity probe (optional)

SAFETY Students should handle wires with caution. The wires may become hot during the activity.

EXPECTED OUTCOME When ions are present in solution, the solution conducts an electric current.

ANALYZE AND CONCLUDE

1. Solutions of vinegar, sodium chloride, and baking soda (and maybe tap water) produced bubbles. Distilled water and sugar solution (and maybe tap water) do not produce bubbles.
2. The solutions in which bubbles were produced also conduct an electric current. These solutions contain ions.
3. *Sample answer:* A larger number of batteries will increase the current, which will, in turn, cause the rate at which the bubbles appear to increase.

FOR ENRICHMENT **Ask** What gases form the bubbles you observe? *(hydrogen and oxygen)* **Ask** What is the source of these gases? *(water)* Have students collect the gases produced and check them for the presence of hydrogen and oxygen. Hydrogen will burn when a lit splint is placed in it, and a glowing split will begin to flame when placed in oxygen.

Another characteristic property of ionic compounds relates to conductivity. **Ionic compounds can conduct an electric current when melted or dissolved in water.** When sodium chloride is melted, the orderly crystal structure breaks down. As Figure 7.11a shows, if a voltage is applied across this molten mass, cations migrate freely to one electrode and anions migrate to the other. This movement of ions allows electric current to flow between the electrodes through an external wire. For a similar reason, ionic compounds also conduct electric current if they are dissolved in water. When dissolved, the ions are free to move about in the solution.

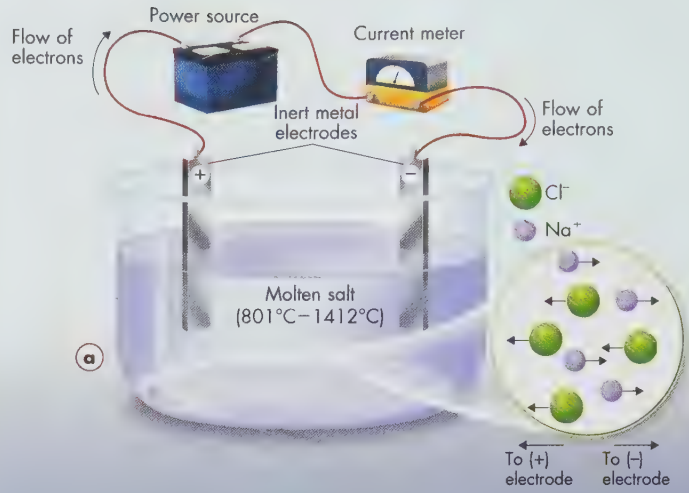

Figure 7.11 Molten NaCl
Sodium chloride melts about about 800°C. **a.** If a voltage is applied to molten NaCl, positive sodium ions move to the negative electrode, and negative chloride ions move to the positive electrode. **b.** This solar facility uses molten NaCl for its ability to absorb and hold a large quantity of heat, which is used to generate electricity.

Focus on ELL

4 LANGUAGE PRODUCTION Have students work in groups of four to complete the Quick Lab. Make sure each group has ELLs of varied language proficiencies, so that more proficient students can help less proficient ones. Have students work according to their proficiency level.

BEGINNING:

LOW Make sure students know what the terminal of a battery is. Discuss each step before groups perform it, using the photo to increase their understanding.

HIGH Recreate the procedure as a numbered list of steps to follow.

INTERMEDIATE: LOW/HIGH Provide students with an organized and labeled chart to complete during the Analyze and Conclude section.

ADVANCED: LOW/HIGH Perform the enrichment activity as a demo and have students write a summary of what happens.

Quick Lab

Purpose To show that ions in solution conduct an electric current

Materials

- 3 D-cell batteries
- masking tape
- 2 30-cm lengths of bell wire with ends scraped bare
- clear plastic cup
- distilled water
- tap water
- vinegar (acetic acid, $C_2H_4O_2$)
- table sugar (sucrose, $C_{12}H_{22}O_{11}$)
- table salt (sodium chloride, NaCl)
- baking soda (sodium hydrogen carbonate, $NaHCO_3$)

Solutions Containing Ions

Procedure

1. Tape the batteries together so the positive end of one touches the negative end of another. Tape the bare end of one wire to the positive terminal of the battery assembly and the bare end of the other wire to the negative terminal.
CAUTION *Bare wire ends can be sharp and scratch skin. Handle with care.*
2. Half fill the cup with distilled water. Hold the bare ends of the wires close together in the water.
3. Look for the production of bubbles. They are a sign that the solution conducts electric current.
4. Repeat Steps 2 and 3 with tap water, vinegar, and concentrated solutions of table sugar, table salt, and baking soda.

Analyze and Conclude

1. **Observe** Which samples produced bubbles of gas? Which samples did not produce bubbles of gas?
2. **Draw Conclusions** Which samples conducted an electric current? What do these samples have in common?
3. **Predict** Would you expect the same results if you used only one battery? If you used six batteries? Explain your answers.

7.2 LessonCheck

12. **Describe** How can you describe the electrical charge of an ionic compound?
13. **Identify** What properties characterize ionic compounds?
14. **Apply Concepts** Write the correct chemical formula for the compounds formed from each pair of elements.
    a. potassium and sulfur
    b. calcium and oxygen
    c. sodium and oxygen
    d. aluminum and nitrogen
15. **Describe** Write formulas for each compound.
    a. barium chloride
    b. magnesium oxide
    c. lithium oxide
    d. calcium fluoride
16. **Describe** How can you describe the arrangement of sodium ions and chloride ions in a crystal of sodium chloride?
17. **Relate Cause and Effect** Why do ionic compounds conduct electric current when they are melted or dissolved in water?
18. **Apply Concepts** Read about restoring electrolytes on page R4 of the Elements Handbook. Write electron configurations for the two principal ions found in body fluids.

BIG IDEA BONDING AND INTERACTIONS

19. Which pairs of elements are likely to form ionic compounds? Explain your choices and write the formulas for the compounds that will form.
    a. Cl, Br
    b. K, He
    c. Li, Cl
    d. I, Na

Lesson Check Answers

12. electrically neutral
13. usually solids at room temperature; have high melting points; conduct an electric current when melted or dissolved in water
14. **a.** K_2S **b.** CaO **c.** Na_2O **d.** AlN
15. **a.** $BaCl_2$ **b.** MgO **c.** Li_2O **d.** CaF_2
16. Acceptable answers should describe a solid containing positive sodium ions and negative chloride ions in an alternating, regular, and repeating three-dimensional pattern.
17. The ions are free to move.
18. Na^+: $1s^2 2s^2 2p^6$ K^+: $1s^2 2s^2 2p^6 3s^2 3p^6$
19. **a.** not likely, both form cations
    b. not likely, helium is a noble gas
    c. LiCl
    d. NaI

Extend

Connect to TECHNOLOGY

Ask for a show of hands of students who are familiar with the term *liquid crystal display* (LCD). Identify any computer monitors or other items in the classroom that have an LCD screen. Explain that LCDs use a type of matter called liquid crystals to display the information or images they see on the LCD screens. Have students use the internet to discover the properties of liquid crystals and why they have such widespread use. Have students report their findings to the class.

Evaluate

Informal Assessment

Create a game where groups of three students compete to win the Ionic Crystal award. Give each group the name of an ionic compound; have one group member identify the cation, have one group member identify the anion, and have one group member determine the ratio of cations to anions in the given compound. If groups are successful then have them switch positions in their group and give them the name of another compound. Repeat again until each group member has taken turns identifying a cation, an anion, and the ratio. If the group successfully completes three rounds of the game, award them the "Ionic Crystal." Then have students complete the 7.2 Lesson Check.

Reteach

Emphasize that an ionic solid is a collection of independent ions. Explain that there is no joining of individual particles to form molecules. State that each ion "belongs" as much to one of its nearest neighbors as it belongs to any other. Point out that the arrangement in an ionic crystal is such that each ion is surrounded by ions of opposite charge, which produces a strong bonding force. Work through several examples to be sure students understand this important point.

CHEMISTRY & YOU Discuss the process of nucleation with students. Then, model nucleation and crystal growth using square blocks or metal cubes. Let one block represent the nucleation crystal. Stack additional blocks on and around the nucleation block to form a crystalline shape. Pose the following question to students: *What interactions do you think occur between the individual crystals to create the larger crystal?* You may need to guide students in the following ways:

- Have students examine the arrangement of sodium and chloride ions in Figure 7.9.
- Ions along the edge of one crystal can interact with ions along the edge of another crystal.
- Have students consider how crystals might share ions along their edges and faces.

Explain

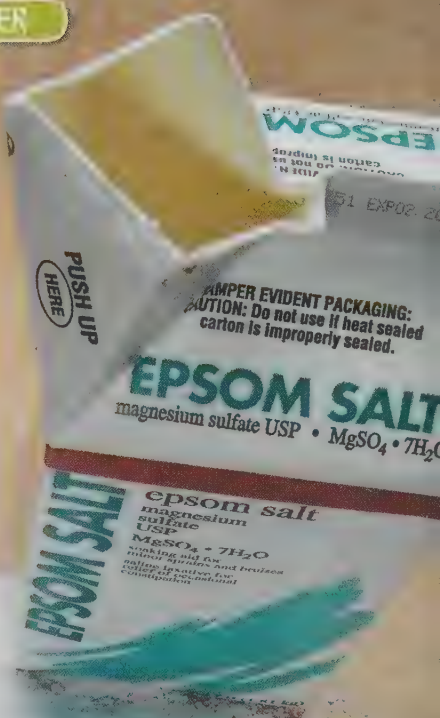
APPLY CONCEPTS After students read the feature, start a discussion of properties of ionic crystals. **Ask** What keeps the ions in their orderly arrangements? *(The electrostatic forces among them.)* **Ask** *Why don't ionic crystals conduct electricity?* (They do not have free electrons or ions.) **Ask** What does "growing a crystal" mean? *(The crystal starts from a small particle and becomes larger as more and more ions attach to the crystal.)*

Extend

Connect to GEOLOGY

In nature, large crystals with clearly defined faces can grow only if there is plenty of free space and the minerals are available from the environment. Molten rock can form crystals if it cools slowly enough that the ions can settle into an orderly arrangement. If the rock cools quickly, such as during a volcanic eruption, the rock is glassy instead of crystalline. Have students look back at the giant crystals on the first page of this chapter. Explain that these crystals in Mexico's Cave of Crystals grew because they were surrounded by very warm water rich in minerals. When the water was pumped out of the cave and the crystals were discovered, the crystals stopped growing.

Answers



THINK ABOUT IT

1. Both crystals have an orderly shape. The sea salt crystals look like little cubes. The Epson salt crystals are shaped like needles.
2. 2+
3. Possible factors are rate of cooling and purity of the solution.

Ionic Crystals

What ionic crystal is essential to human life, was found among the funeral offerings of ancient Egyptians, created and destroyed empires, and is now commonly used to season foods? If you said table salt, you'd be right! Table salt, or sodium chloride (NaCl) is an ionic compound composed of sodium cations (Na^+) and chloride anions (Cl^-).

Crystals of ionic compounds, such as sodium chloride, can be grown by a process called nucleation. During nucleation, the ionic compound that is to be crystallized is dissolved in a solvent, such as water. In the dissolution process, the positive and negative ions break away from each other. As the solvent is removed, the ions join together again to form a repeating three-dimensional pattern. Sodium chloride has a cubic crystal structure, but different ionic compounds form crystals with different shapes. Try the On Your Own activity at home and compare the shapes of two different ionic crystals.

On Your Own

1. For this activity you will need sea salt, **Epsom salts, hot tap water, 2 pie plates, a measuring cup, and a stirring rod or spoon.** Epsom salts can be found in the medicine department of most grocery stores.
2. Mix together 1/4 cup of the sea salt and 1/4 cup of hot water in one of the pie plates. Stir to dissolve most of the salt. In the other pie plate, mix together 1/4 cup of the Epsom salts and 1/4 of hot water. Again, stir until most of the salt has dissolved.
3. Place both pie plates in the refrigerator for three hours. Once the crystals have formed, compare the shapes of the crystals made from the two substances. Record your observations.

Think About It

1. **Compare and Contrast** Describe the shapes of the crystals of sea salt and Epsom salts. How are they the same? How are they different?
2. **Identify** Epsom salts are magnesium sulfate ($MgSO_4$) crystals. A magnesium sulfate formula unit consists of a magnesium cation and a sulfate (SO_4^{2-}) anion. What is the charge on the magnesium cation?
3. **Control Variables** What factors do you think affect crystal growth? Identify two possible factors, then repeat the activity to test your hypotheses.

7.3 Bonding in Metals

C.3.3 Chemical bonds and intermolecular attractions

CHEMISTRY & YOU

Q: *What are some properties that are unique to metals?* You have probably seen decorative fences, railings, or weather vanes made of a metal called wrought iron. Wrought iron is a very pure form of iron that contains trace amounts of carbon. It is a tough, malleable, ductile, and corrosion-resistant material that melts at a very high temperature. These properties derive from the way that metal ions form bonds with one another.

Key Questions

- *How can you model the valence electrons of metal atoms?*
- *Why are alloys important?*

Vocabulary

- metallic bond
- alloy

Metallic Bonds and Metallic Properties

How can you model the valence electrons of metal atoms?

Metals consist of closely packed cations and loosely held valence electrons rather than neutral atoms. **The valence electrons of atoms in a pure metal can be modeled as a sea of electrons.** That is, the valence electrons are mobile and can drift freely from one part of the metal to another. **Metallic bonds** are the forces of attraction between the free-floating valence electrons and the positively charged metal ions. These bonds hold metals together.

Properties of Metals The sea-of-electrons model explains many physical properties of metals. Metals are good conductors of electric current because electrons can flow freely in the metal. As electrons enter one end of a bar of metal, an equal number of electrons leaves the other end. Metals are ductile—that is, they can be drawn into wires, as shown in Figure 7.12. Metals are also malleable, which means that they can be hammered or pressed into shapes.

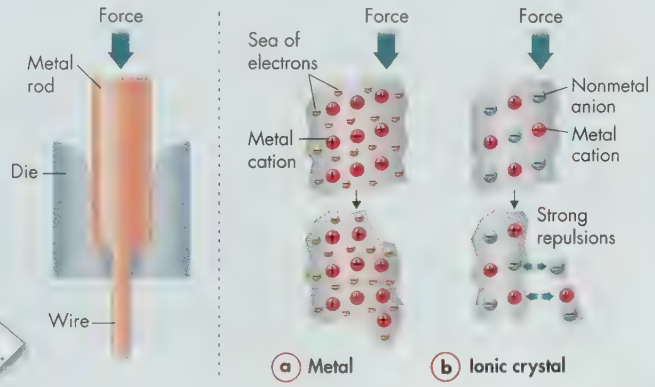


Figure 7.12 Comparing Metals and Ionic Compounds
A metal rod can be forced through a narrow opening to produce wire. **a.** As this occurs, the metal changes shape but remains in one piece. **b.** If an ionic crystal were forced through the opening, it would shatter.
Interpret Diagrams *What causes the ionic crystal to break apart?*

Go online to compare metal vs. ionic compounds.

Focus on ELL

1 CONTENT AND LANGUAGE Read the key questions, and write the terms *model, valence electrons, metal,* and *alloy* on the board along with their phonetic spelling. State each word aloud and discuss the meaning of each word. Then help students rephrase the key questions in their own words.

2 FRONTLOAD THE LESSON Hold up a large crystal (preferably one that is long in shape) and a piece of wire or a metal strip. Have a student volunteer to attempt to bend each item. Ask students to use what they know about ionic bonding to explain why the crystal could not be bent. Then, ask students to predict what the difference in bonding in metal crystals is that allows the metal strip to be bent. Tell students that they will explore this concept during the lesson.

3 COMPREHENSIBLE INPUT Have students learn about close packing arrangements by packing table tennis balls or small foam balls into a box.

Key Objectives

- **7.3.1 MODEL** the valence electrons of metal atoms.
- **7.3.2 DESCRIBE** the arrangement of atoms in a metal.
- **7.3.3 EXPLAIN** the importance of alloys.

Engage

CHEMISTRY & YOU Have students read the text that opens the lesson. Ask students to offer suggestions of how metal ions could form bonds with other metal ions. (Do not provide the correct answer yet.)

Access Prior Knowledge

To assess students' prior knowledge about metals, list the adjectives *tough, malleable, ductile,* and *corrosion-resistant* on the board. **Ask** Which term means able to be hammered? *(malleable)* Which means can be drawn into wires? *(ductile)*

IN ACADEMIC STANDARDS for SCIENCE

C.3.3 Compare and contrast ionic, covalent network, metallic and polar and non-polar molecular crystals with respect to constituent particles, strength of bonds, melting and boiling points, and conductivity; provide examples of each type.

Foundations for Reading

BUILD VOCABULARY From what they know about the terms *metallic* and *bond,* have students infer the meaning of *metallic bond.*

READING STRATEGY Tell students that before they read, they should write down three things they know about metals. Then, after they read a section, they should explain how the information they already knew about metals helped them to learn something new.

Explore

Teacher Demo

PURPOSE Students compare copper metal and a copper compound.

MATERIALS copper metal or alloy, copper-containing ionic compound

PROCEDURE Show the class a small sample of elemental copper or a copper alloy and a sample of a copper-containing crystalline ionic mineral such as chalcocite (Cu_2S). Wearing safety glasses and standing far from the students, smash both samples with a hammer. Discuss why the two substances respond differently to the stress of the hammer blow.

EXPECTED OUTCOMES The elemental copper will flatten but not break because the cations and electrons are mobile; the crystal will shatter.

Explain

Metallic Bonds and Metallic Properties

START A CONVERSATION Lead a class discussion on the concept of "close packing" of metal cations in pure metals. Use the three different close-packing arrangements shown in Figure 7.14 as a reference. Emphasize that the concept of close packing also relates to more than just metal atoms. Have the students describe other examples of close packing.

CHEMISTRY & YOU Both metals and ionic compounds are held together by strong attractive forces. In ionic solids, the attractions are between ions with opposite charges. In metals, the attractions are between metal ions and mobile valence electrons.

Both the ductility and malleability of metals can be explained in terms of the mobility of valence electrons. A sea of drifting valence electrons insulates the metal cations from one another. When a metal is subjected to pressure, the metal cations easily slide past one another like ball bearings immersed in oil. In contrast, if an ionic crystal is struck with a hammer, the blow tends to push the positive ions close together. The positive ions repel one another, and the crystal shatters.

CHEMISTRY & YOU

Q: *How are metals and ionic compounds different? How are they similar?*

Crystalline Structure of Metals The next time you visit a grocery store, take a look at how the apples or oranges are stacked. More than likely, they will have a close-packed arrangement, as shown in Figure 7.13. This arrangement helps save space while allowing as many oranges as possible to be stacked up high.

Similar close-packed arrangements can be found in the crystalline structures of metals. You may be surprised to learn that metals are crystalline. In fact, metals that contain just one kind of atom are among the simplest forms of all crystalline solids. Metal atoms are arranged in very compact and orderly patterns. For spheres of identical size, such as metal atoms, several closely packed arrangements are possible. Figure 7.14 on the following page shows three such arrangements: body-centered cubic, face-centered cubic, and hexagonal close-packed.

In a body-centered cubic structure, every atom (except those on the surface) has eight neighbors. The metallic elements sodium, potassium, iron, chromium, and tungsten crystallize in a body-centered cubic pattern. In a face-centered cubic arrangement, every atom has twelve neighbors. Among the metals that form a face-centered cubic structure are copper, silver, gold, aluminum, and lead. In a hexagonal close-packed arrangement, every atom also has twelve neighbors. However, because of its hexagonal shape, the pattern is different from the face-centered cubic arrangement. Metals that have a hexagonal close-packed crystal structure include magnesium, zinc, and cadmium.

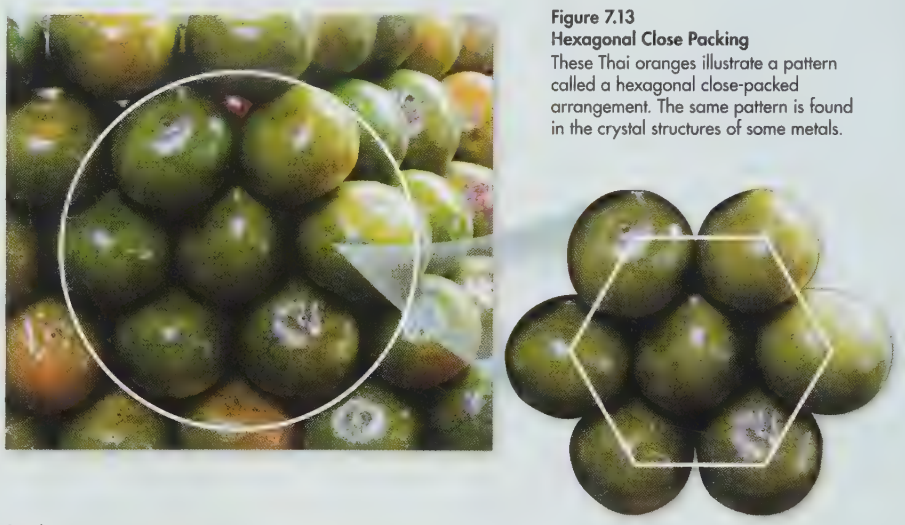

Figure 7.13
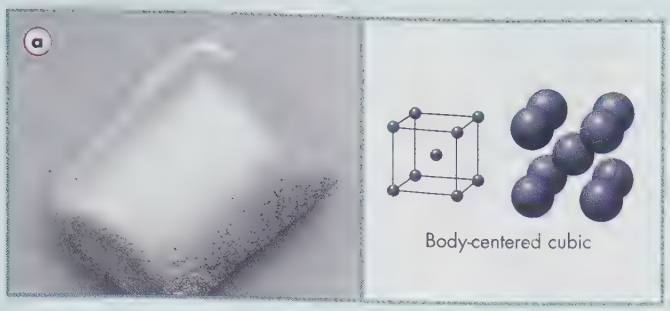
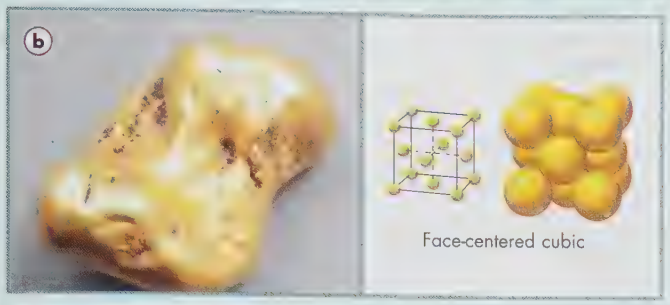
Hexagonal Close Packing
These Thai oranges illustrate a pattern called a hexagonal close-packed arrangement. The same pattern is found in the crystal structures of some metals.



UbD Check for Understanding



The Essential Question **How does metallic bonding affect the properties of metals?**

Assess students' understanding of this Essential Question by giving them one minute to respond to the following prompt:

How can the conductivity of metals be explained? *(Electrons can flow in and out of a metal because the valence electrons are not fixed, but float freely around the positively charged metal ions.)*

ADJUST INSTRUCTION If students are having difficulty answering, have them consider what they have learned about valence electrons and apply that to the concept of metallic bonding as they examine Figure 7.12.Then ask them to answer the prompt again.

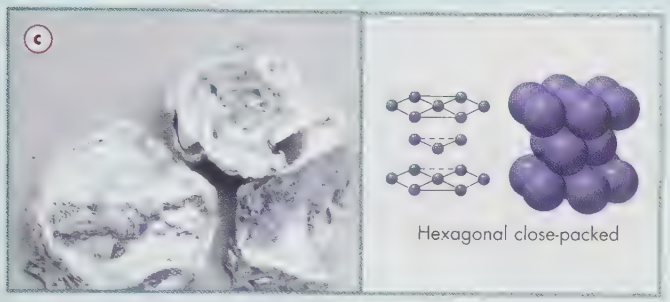


Figure 7.14 Crystalline Structures of Metals
Metal atoms crystallize in characteristic patterns. **a.** Chromium atoms have a body-centered cubic arrangement. **b.** Gold atoms have a face-centered cubic arrangement. **c.** Zinc atoms have a hexagonal close-packed arrangement.
Interpret Diagrams *Which of these arrangements is the most closely packed?*

Alloys

Why are alloys important?

Every day you use metallic items, such as utensils. However, very few of these objects are made out of a single kind of metal. Instead, most of the metals you encounter are alloys. **Alloys** are mixtures of two or more elements, at least one of which is a metal. Brass, for example, is an alloy of copper and zinc.

Alloys are important because their properties are often superior to those of their component elements. Sterling silver (92.5 percent silver and 7.5 percent copper) is harder and more durable than pure silver, yet is still soft enough to be made into jewelry and tableware. Bronze is an alloy generally containing seven parts copper to one part tin. Bronze is harder than copper and is easier to cast into molds. Nonferrous (non-iron) alloys, such as bronze, copper-nickel, and aluminum alloys, are commonly used to make coins.

Differentiated Instruction

L3 ADVANCED STUDENTS Have students develop formulas for calculating the density of a metal given the atomic radius of the metal and the cubic unit cell packing arrangement of the metal atoms. Use sodium, potassium, iron, chromium, and tungsten for body-centered cubic metals. Use copper, silver, gold, aluminum, and lead for face-centered cubic metals. The students may need to make models to see geometric relationships more clearly.

ELL ENGLISH LANGUAGE LEARNERS English language learners may have difficulty understanding the pronunciation of the term *alloy*, despite the pre-lesson exposure to the term. Write the word on the board again, along with its phonetic spelling, and pronounce it slowly. Ask students with higher English proficiencies to translate the term into their native language for their lower proficiency students if the translation is unavailable in the glossary at the end of this text.

Alloys

Teacher Demo

PURPOSE Students compare models of interstitial and substitutional alloys.

MATERIALS styrofoam balls of different sizes and colors, toothpicks

PROCEDURE Use styrofoam balls to illustrate the crystal structures of interstitial and substitutional alloys. Use toothpicks to hold the "atoms" together. Point out that brass is a substitutional alloy in which copper atoms are replaced by similarly sized zinc atoms. Steel is an interstitial alloy in which relatively small carbon atoms occupy the interstices between closely packed iron atoms.

EXPECTED OUTCOME Students should be able to distinguish between the two types of alloys.

Answers

FIGURE 7.12 repulsions between ions of like charge
FIGURE 7.14 face-centered cubic

Extend

Connect to ENGINEERING

Explain that materials for a building must be able to withstand the stresses that a building undergoes. Tensile stress can be observed when a building beam sags. The bottom of a beam undergoes tensile stress as it is slightly stretched. The top of a beam undergoes compression stress, which results when two forces push toward each other through a solid. The top of the beam is compressed as it is slightly shortened. A building undergoes shear stress in a strong wind. In shear stress, forces are applied from different directions, and the building might twist or break. Have students research how steel and iron differ in their response to these types of stresses and report their findings to the class.

Evaluate

Informal Assessment

Have students explain the cause-and-effect relationship between metallic bonding and the properties of metals. Then ask students to explain how this relates to the conductivity of metals. *(Metal ions are surrounded by electrons that can move freely around the metal cations. This freedom of movement allows metallic bonds to remain intact if the metal is stretched or hammered. This freedom of electron movement also allows metals to conduct electricity. As electrons enter the metal as part of an electric current, an equal number leave the opposite end of the metal. The electrons in between those electrons can flow freely toward the opposite end.)* **Ask** If a metal is alloyed with another substance, such as iron and carbon to make steel, how might the properties of the metal be affected? *(Sample response: the resulting alloy may be more corrosion-resistant, stronger, tougher or harder.)* Then have students complete the 7.3 Lesson Check.

Reteach

As a class, create a two-column chart comparing the characteristics of chemical bonding in ionic compounds and chemical bonding in pure metals.

The most important alloys today are steels. The principal elements in most steels, in addition to iron and carbon, are boron, chromium, manganese, molybdenum, nickel, tungsten, and vanadium. As a result, steels have a wide range of useful properties, such as corrosion resistance, ductility, hardness, and toughness. Figure 7.15 shows some items made of common alloys and their compositions.

Alloys can form from their component atoms in different ways. If the atoms of the components in an alloy are about the same size, they can replace each other in the crystal. This type of alloy is called a substitutional alloy. If the atomic sizes are quite different, the smaller atoms can fit into the interstices (spaces) between the larger atoms. Such an alloy is called an interstitial alloy. In the various types of steel, for example, carbon atoms occupy the spaces between the iron atoms. Thus, steels are interstitial alloys.

Figure 7.15 Common Alloys
Alloys are composed of two or more elements. The compositions (by mass) of sterling silver, cast iron, and stainless steel are shown.

7.3 LessonCheck

20. **Describe** How do chemists model the valence electrons of metal atoms?

21. **Explain** Why are alloys more useful than pure metals?

22. **Explain** What is meant by the terms *ductile* and *malleable?*

23. **Relate Cause and Effect** Why is it possible to bend metals but not ionic crystals?

24. **Use Analogies** How is the arrangement of fruit in a stack of oranges similar to the way some metal atoms are arranged in metallic crystals?

25. **Describe** Name two widely used alloys and describe some of their uses.

BIG IDEA BONDING AND INTERACTIONS

26. Describe how the sea-of-electrons model is used to explain the physical properties of metals.

Lesson Check Answers

20. metal cations surrounded by a sea of mobile valence electrons

21. The properties of alloys are often superior to their component elements.

22. ductile: can be drawn into wires; malleable: can be hammered into different shapes

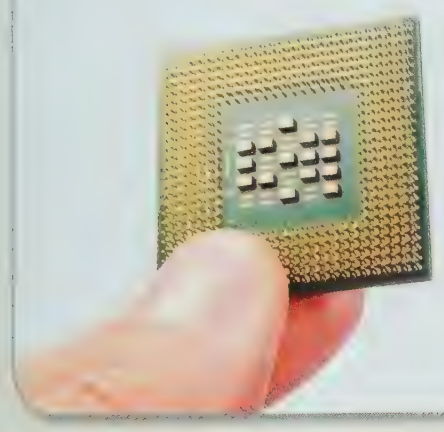
23. Under pressure, the cations in a metal slide past each other. The ions in ionic crystals are forced into each other by the rigid structure.

24. The arrangements are orderly and allow the individual items (fruit or cations) to be closely packed.

25. *Sample answer:* Sterling silver used in jewelry is 92.5% silver and 7.5% copper; bronze used in casting is 7 parts copper and 1 part tin.

26. Metal cations are surrounded by free-floating electrons. When metals are hammered or drawn, the cations move past each other.

7 Study Guide



BIG IDEA
BONDING AND INTERACTIONS

Atoms form positive ions (cations) by losing valence electrons and form negative ions (anions) by gaining valence electrons. The electrostatic forces between the oppositely charged ions hold the cations and anions together in an ionic compound. Ionic compounds generally have high melting points and can conduct an electric current in solution and in the molten state. Metals are made up of closely packed cations surrounded by a sea of electrons. The sea-of-electrons model explains why metals are good conductors of electric current and why they are ductile and malleable.

7.1 Ions

- To find the number of valence electrons in an atom of a representative element, simply look at its group number.
- A positively charged ion, or a cation, is produced when an atom loses one or more valence electrons.
- An anion is produced when an atom gains one or more valence electrons.

- valence electron (194)
- electron dot structure (195)
- octet rule (195)
- halide ion (199)

7.2 Ionic Bonds and Ionic Compounds

- Although they are composed of ions, ionic compounds are electrically neutral.
- Most ionic compounds are crystalline solids at room temperature.
- Ionic compounds generally have high melting points.
- Ionic compounds can conduct an electric current when melted or dissolved in water.

- ionic compound (201)
- ionic bond (201)
- chemical formula (202)
- formula unit (202)
- coordination number (205)

7.3 Bonding in Metals

- The valence electrons of atoms in a pure metal can be modeled as a sea of electrons.
- Alloys are important because their properties are often superior to those of their component elements.

- metallic bond (209)
- alloy (211)

UbD Performance Tasks

MODELING IONIC CRYSTALS Have students choose three ionic compounds and do research to find out their crystal structures. Then have students use modeling clay and toothpicks to make three-dimensional models of each crystal structure.

QUENCHING—NOT JUST FOR THIRST Alloys and metals are often quenched in water after being heated and shaped. Have students research and report on the effects of quenching on the crystalline structure of metals and alloys. Also, ask them to compare the resulting crystals to ionic crystals. Reports should include any necessary graphics and explain any changes in metal properties that occur as a result of the quenching process.

Evaluate

Review and Assessment Materials

PROBLEM SETS Have students practice more formula writing problems by using the Chapter 7 Online Problem Set.

VIRTUAL LABS Have students complete a virtual lab as an in-class or take-home assignment to help reinforce the concept of ionic bonding.

Study Tip

Write and answer questions about the content of the chapter. For Chapter 7, you might **ask** the following questions, which require students to summarize the information contained in the chapter.

- What information does the electron dot structure of an element provide? *(the number of valence electrons)*
- In most cases, what is the stable electron configuration of an elemental ion? *(In most cases, a stable configuration is characterized by an octet of valence electrons; the configuration is isoelectronic with that of a noble gas.)*
- Why does NaCl dissolved in water conduct electricity? *(In water, the ionic compound breaks apart into Na^+ and Cl^- ions that are free to move in the solution.)*
- What is the theory of bonding in pure metals? *(metal cations held together by a pool of mobile valence electrons)*

7 Assessment

* Solutions appear in Appendix E

Lesson by Lesson

7.1 Ions

27. What is a valence electron?

***28.** To which group in the periodic table does each of the following elements belong? How many valence electrons do atoms of each element have?

a. nitrogen **d.** barium
b. lithium **e.** bromine
c. phosphorus **f.** carbon

29. Write electron dot structures for each of the following elements:

a. Cl **c.** Al
b. S **d.** Li

30. Describe two ways that an ion forms from an atom.

***31.** How many electrons must an atom of each element lose to attain a noble-gas electron configuration?

a. Ca **c.** Li
b. Al **d.** Ba

32. Write the symbol for the ion formed when each of the following elements loses its valence electrons.

a. aluminum **d.** potassium
b. lithium **e.** calcium
c. barium **f.** strontium

33. Why do nonmetal atoms tend to form anions when they react to form compounds?

***34.** How many electrons must be gained by each of the following atoms to achieve a stable electron configuration?

a. N **c.** Cl
b. S **d.** P

***35.** What is the formula of the ions formed when atoms of the following elements gain or lose valence electrons and attain noble-gas configurations?

a. sulfur **c.** fluorine
b. sodium **d.** phosphorus

36. State the number of electrons either lost or gained in forming each ion.

a. Br^{-} **e.** Ca^{2+}
b. Na^{+} **f.** Cu^{+}
c. As^{3-} **g.** H^{-}
d. Ba^{2+} **h.** Cu^{2+}

37. Name each ion in Problem 36. Identify each as an anion or a cation.

7.2 Ionic Bonds and Ionic Compounds

38. Define an ionic bond.

39. Explain why ionic compounds are electrically neutral.

***40.** Which of the following pairs of atoms would you expect to combine chemically to form an ionic compound?

a. Li and S **d.** F and Cl
b. O and S **e.** I and K
c. Al and O **f.** H and N

41. Which of the following pairs of elements will not form ionic compounds?

a. sulfur and oxygen
b. sodium and calcium
c. sodium and sulfur
d. oxygen and chlorine

42. How can you represent the composition of an ionic compound?

***43.** Identify the kinds of ions that form each ionic compound.

a. calcium fluoride, CaF_2
b. aluminum bromide, $AlBr_3$
c. lithium oxide, Li_2O
d. aluminum sulfide, Al_2S_3
e. potassium nitride, K_3N

44. Write the formulas for the ions in the following compounds:

a. KCl **c.** $MgBr_2$
b. BaS **d.** Li_2O

45. Most ionic substances are brittle. Why?

46. Explain why molten $MgCl_2$ does conduct an electric current although crystalline $MgCl_2$ does not.

Focus on ELL

5 ASSESS UNDERSTANDING Engage students in discussing the chapter's key concepts and vocabulary. Encourage them to identify learning strategies they felt were most helpful and those they felt were difficult.

BEGINNING: LOW/HIGH Provide students with a two-column chart which has randomly ordered vocabulary words in one column and definitions in the other. Have students match each word with its definition.

INTERMEDIATE: LOW/HIGH Provide students with a list of one key question from each lesson. Have them write a short answer to each.

ADVANCED: LOW/HIGH Have students write a summary statement for each lesson describing what they have learned.

7.3 Bonding in Metals

*47. How can you describe the arrangement of atoms in metals?

48. Explain briefly why metals are good conductors of electric current.

*49. Name the three crystal arrangements of closely packed metal atoms. Give an example of a metal that crystallizes in each arrangement.

50. Name some alloys that you have used or seen today.

51. Explain why the properties of all steels are not identical.

Understand Concepts

52. Construct a table that shows the relationship among the group number, valence electrons lost or gained, and the formula of the cation or anion produced for the following metallic and nonmetallic elements: Na, Ca, Al, N, S, Br.

53. Write electron dot structures for the following elements.

a. C
b. Be
c. O
d. F
e. Na
f. P

54. Show the relationship between the electron dot structure of an element and the location of the element in the periodic table.

*55. In terms of electrons, why does a cation have a positive charge?

56. Why does an anion have a negative charge?

57. The spheres below represent the relative diameters of atoms or ions. Rearrange the sequences in (a) and (b) so the relative sizes of the particles correspond to the increasing size of the particles as shown in the illustration.

a. oxygen atom, oxide ion, sulfur atom, sulfide ion
b. sodium atom, sodium ion, potassium atom, potassium ion

*58. Write the name and symbol of the ion formed when

a. a sulfur atom gains two electrons.
b. an aluminum atom loses three electrons.
c. a nitrogen atom gains three electrons.
d. a calcium atom loses two electrons.

*59. Write electron configurations for the 2+ cations of these elements.

a. Fe
b. Co
c. Ni

60. Write electron configurations for the 3+ cations of these elements.

a. chromium
b. manganese
c. iron

61. Write the symbol for the ion formed when each element gains electrons and attains a noble-gas electron configuration.

a. Br
b. H
c. As
d. Se

*62. Write electron configurations for the following atoms and ions, and comment on the result.

a. Ar
b. Cl^-
c. S^{2-}
d. P^{3-}

63. Write electron configurations for the following atoms and ions and comment on the result.

a. N^{3-}
b. O^{2-}
c. F^-
d. Ne

64. Name the first four halogens. What group are they in, and how many valence electrons does an atom of each element have?

65. Write complete electron configurations for the following atoms and ions. For each group, comment on the results.

a. Ar, K^+, Ca^{2+}
b. Ne, Na^+, Mg^{2+}, Al^{3+}

66. If ionic compounds are composed of charged particles (ions), why isn't every ionic compound either positively or negatively charged?

*67. Which of the following compounds are most likely not ionic?

a. H_2O
b. Na_2O
c. CO_2
d. CaS
e. SO_2
f. NH_3

64. fluorine, chlorine, bromine, and iodine; Group 7A, 7 valence electrons

65. a. $1s^2 2s^2 2p^6 3s^2 3p^6$
b. $1s^2 2s^2 2p^6$;
Each has a noble-gas electron configuration

66. The positively charged cations exactly balance the negatively charged anions.

67. a, c, e, f

Answers

LESSON 7.3

47. *Sample answer:* Atoms in metals are arranged in a compact and orderly manner.

48. They have many mobile valence electrons. Electrons in the current replace the electrons leaving the metal.

49. body-centered cubic: Na, K, Fe, Cr, or W; face-centered cubic: Cu, Ag, Au, Al, or Pb; hexagonal close-packed: Mg, Zn, or Cd

50. Answers could include table-ware, steel in cars and buses, high-speed dental drill bits, solder in stereos and televisions, and structural steel in buildings.

51. The properties of the steel will vary according to its composition. In addition to iron, steel can contain varying amounts of carbon and such metals as chromium, nickel, and molybdenum.

UNDERSTAND CONCEPTS

52.

Group number	Valence electrons lost or gained	Formula of ion
1A	1	Na^+
2A	2	Ca^{2+}
3A	3	Al^{3+}
5A	3	N^{3-}
6A	2	S^{2-}
7A	1	Br^-

53. a. ·Ċ· c. ·Ö· e. Na·
b. ·Be· d. :F̈· f. :P·

54. For the representative elements the number of electrons in the electron dot structure is the group number.

55. It has lost valence electrons.

56. It has gained valence electrons.

57. a. oxygen atom, sulfur atom, oxide ion, sulfide ion
b. sodium ion, potassium ion, sodium atom, potassium atom

58. a. sulfide ion (anion), S^{2-}
b. aluminum ion (cation), Al^{3+}
c. nitride ion (anion), N^{3-}
d. calcium ion (cation), Ca^{2+}

59. a. $1s^2 2s^2 2p^6 3s^2 3p^6 3d^6$
b. $1s^2 2s^2 2p^6 3s^2 3p^6 3d^7$
c. $1s^2 2s^2 2p^6 3s^2 3p^6 3d^8$

60. a. $1s^2 2s^2 2p^6 3s^2 3p^6 3d^3$
b. $1s^2 2s^2 2p^6 3s^2 3p^6 3d^4$
c. $1s^2 2s^2 2p^6 3s^2 3p^6 3d^5$

61. a. Br^- b. H^- c. As^{3-} d. Se^{2-}

62. All have the noble-gas configuration of $1s^2 2s^2 2p^6 3s^2 3p^6$.

63. All are $1s^2 2s^2 2p^6$. All have the same configuration as neon.

ASSESSMENT

Answers

UNDERSTAND CONCEPTS

68. **a.** $BaBr_2$ **b.** Al_2S_3 **c.** K_3N

69. Their outmost occupied energy levels are filled.

70. **a.** Fe_2O_3
b. PbO_2
c. Li_2O
d. MgO

71. No, the packing of ions in a crystalline structure depends on a number of factors including the relative sizes of the ions. The coordination number of an element can vary from compound to compound.

72. 12

73. Hexagonal close-packed unit cells have twelve neighbors for, every atom or ion. Face-centered cubic unit cells also have twelve neighbors for every atom or ion, with an atom or ion in the center of each face. Body-centered cubic unit cells have eight neighbors for every atom or ion, with an atom or ion at the center of each cube.

74. Brass is a mixture of copper and zinc. The properties of a particular sample of brass will vary with the relative proportions of the two metals.

75. **a.** Cu, Zn **c.** Cu, Sn
b. Ag, Cu **d.** Fe, Cr, Ni, C

THINK CRITICALLY

76. Each dot in the electron dot structure represents a valence electron in the electron configuration diagram.

77. By gaining or losing electrons the atoms of elements achieve a noble-gas electron configuration.

78. No, sodium chloride is composed of equal numbers of sodium ions and chloride ions; the ions are in a 1:1 ratio. Each sodium ion is surrounded by chloride ions, and each chloride is surrounded by sodium ions.

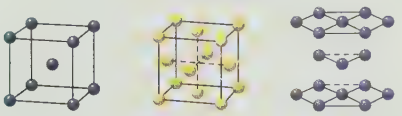
79. **a.** 6A **d.** 6A
b. 7A **e.** 1A
c. 1A **f.** 2A

80. In sodum chloride crystals the sodium and chloride ions vibrate about fixed points; in the molten state, the ions are free to move.

81. Metals are ductile (can be drawn into wires) and malleable (can be hammered into shapes). These changes are possible because a metal consists of metal cations in a sea of valence electrons. When subjected to pressure, the cations easily slide past one another.

82. The spheres are more closely packed in (a); there is less empty space in (a), and a rough count shows 25 spheres in (a) compared with 22 spheres in (b).

*68. Write the formulas for each ionic compound that can be made by combining each of pair of ions.
a. Ba^{2+} and Br^-
b. Al^{3+} and S^{2-}
c. K^+ and N^{3-}



69. The atoms of the noble gas elements are stable. Explain.

70. What is the simplest formula for the compounds that can form when each of these ions combine with an oxide (O^{2-}) ion?
a. Fe^{3+} **c.** Li^+
b. Pb^{4+} **d.** Mg^{2+}

71. Can you predict the coordination number of an ion from the formula of an ionic compound? Explain.

*72. Metallic cobalt crystallizes in a hexagonal close-packed structure. How many neighbors will a cobalt atom have?

73. Explain how hexagonal close-packed, face-centered cubic, and body-centered cubic unit cells are different from one another.

Body-centered cubic | Face-centered cubic | Hexagonal close-packed

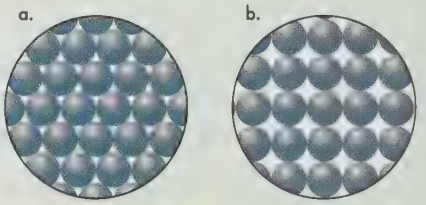
74. The properties of all samples of brass are not identical. Explain.

*75. For each alloy below, list the elements it contains.
a. brass **c.** bronze
b. sterling silver **d.** stainless steel

Think Critically

*76. **Make Generalizations** What is the relationship between the number of electrons in the valence shells in an electron configuration diagram for an atom and the number of dots in the corresponding electron dot structure?

77. **Relate Cause and Effect** Why are many elements more stable as ions than they are as atoms?



78. **Make Generalizations** Is it accurate to describe sodium chloride (NaCl) as consisting of individual particles, each made up of one Na^+ cation and one Cl^- anion? Explain your answer.

*79. **Infer** For each ionic formula, identify the A-group number to which element X belongs.
a. CaX **d.** Al_2X_3
b. MgX_2 **e.** XF
c. X_3N **f.** XS

80. **Compare** How do the motions of sodium ions and chloride ions in molten sodium chloride differ from the motions of these ions in sodium chloride crystals?

81. **Relate Cause and Effect** Two physical properties of metals are ductility and malleability. Explain these properties based on what you know about the valence electrons of metal atoms.

82. **Interpret Diagrams** How atoms and ions are arranged in crystals is not just dependent on size. The spheres in each atomic window below are identical in size. The windows have exactly the same area. In which window are the spheres more closely packed? Explain your reasoning.

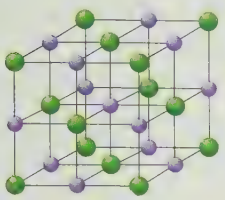
*83. **Compare and Contrast** Describe the similarities and differences between ionic compounds and metals in terms of their physical and chemical characteristics.

84. **Relate Cause and Effect** How does the octet rule explain the large increase in energy between the first and second ionization energies of Group 1A metals?

85. **Infer** An atom of the element M forms a stable ion in an ionic compound with chlorine having the formula MCl_2. In this compound, the ion of element M has a mass number of 66 and has 28 electrons.
a. What is the identity of the element?
b. How many neutrons does the ion have?

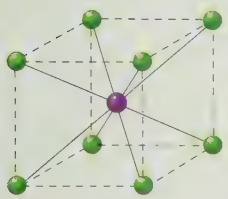
83. Both metals and ionic compounds are composed of ions. Both are held together by electrostatic bonds. Metals always conduct electricity, and ionic compounds conduct only when melted or in water solution. Ionic compounds are composed of cations and anions, but metals are composed of cations and free-floating valence electrons. Metals are ductile, but ionic compounds are brittle.

84. Removal of the first electron results in a very stable electron configuration. Removing a second electron would disrupt that stability.



85. **a.** zinc
b. 38 neutrons

Enrichment



*86. **Apply Concepts** Classify each element in the following list. Will an atom of each element form a cation or an anion, or is the element chemically nonreactive? For the atoms that do form ions during a chemical reaction, write the number of electrons the atom will gain or lose.

a. lithium
b. sodium
c. neon
d. chlorine
e. magnesium

87. **Infer** The chemically similar alkali metal chlorides NaCl and CsCl have different crystal structures, whereas the chemically different NaCl and MnS have the same crystal structures. Why?

Cl^-
Na^+
Sodium chloride (NaCl)

Cl^-
Cs^+
Cesium chloride (CsCl)

88. **Calculate** Silver crystallizes in a face-centered cubic arrangement. A silver atom is at the edge of each lattice point (the corner of the unit cell). The length of the edge of the unit cell is 0.4086 nm. What is the atomic radius of silver?

*89. **Analyze Data** Consider two ionic compounds, NaCl and CaO.

a. In which compound would you expect the electrostatic forces that hold the compound together to be the strongest? Explain your choice.
b. The melting point of NaCl is 801°C. The melting point of CaO is 2614°C. Does this data support your prediction? Why or why not?

Write About Science

90. **Compare** Describe the formation of a cation that is an exception to the octet rule. In your description, compare the electron configuration of the cation to the electron configurations of the nearest noble gases.

91. **Research** Go online and research X-ray diffraction crystallography. How are the samples prepared? How are the X-rays generated and detected? How is this technique used to study the structure of crystalline substances?

CHEMYSTERY

It's Not Easy Being Green

The statue of Ludwig van Beethoven in Central Park is made of bronze. Bronze is an alloy containing copper and tin.

When bronze is exposed to the elements, it reacts with water (H_2O), carbon dioxide (CO_2), and oxygen (O_2) in the air to produce a film of copper(II) carbonate ($CuCO_3$). Copper(II) carbonate is an ionic compound that is blue-green in color. A film of copper(II) carbonate on the Beethoven statue gives the statue its green color. The film also protects the metal against further corrosion.

*92. **Apply Concepts** A copper atom can lose one or two electrons to form a Cu^+ ion or a Cu^{2+} ion, respectively. The charge of the copper ion in $CuCO_3$ is 2+. Write the electron configuration of this cation.

93. **Form an Opinion** Why do you think bronze is often used to create statues?

94. Connect to the **BIG**IDEA How are the properties of the copper(II) carbonate film on the statue different from the properties of the bronze beneath the film? Explain how these properties are a result of the type of bonding present.

ASSESSMENT

CHEMYSTERY **APPLY CONCEPTS** After students have read through the CHEMystery, discuss the principles of ionic and metallic bonding that make the development of the green patina possible. **Ask** What type of bonding occurs? *(The product is an ionic compound composed of copper from the statue and water and carbon dioxide from the air.)*

Ask How is the film able to protect the metal against further corrosion? *(Because the film has a different composition, it doesn't react with air in the same way that the metal does.)*

CHEMYSTERY ANSWERS

92. The configuration is $[Ar]3d^9$.
93. *Sample answer:* Bronze is an attractive metal alloy before and after it forms a patina.
94. The metallically-bonded alloy is able to react with elements in its environment to form an ionic compound, which is less reactive.

Answers

86. **a.** cation: lose $1e^-$ **b.** cation: lose $1e^-$ **c.** unreactive **d.** anion: gain $1e^-$ **e.** cation: lose $2e^-$
87. Na^+ and Cs^+ differ greatly in size. Na^+ and Cl^- are similar in size to Mn^{2+} and S^{2-}.
88. 0.1445 nm
89. **a.** CaO; the electrostatic forces of attraction between Ca^{2+} and O^{2-} are much stronger than the forces between Na^+ and Cl^-.
b. Yes; more energy is needed to overcome the electrostatic attractions in CaO and melt the compound.

WRITE ABOUT SCIENCE

90. An atom of silver has the electron configuration $1s^2 2s^2 2p^6 3s^2 3p^6 3d^{10} 4s^2 4p^6 4d^{10} 5s^1$. To achieve the configuration of the preceding noble gas, krypton, a silver atom would have to lose eleven electrons and form Ag^{11+}. To achieve the configuration of the following noble gas xenon, a silver atom must gain seven electrons and form Ag^{7-}. Because ions with such high charges are unlikely, silver does not achieve a noble-gas configuration. However, if a silver atom loses its $5s^1$ electron, the result is an outer electron configuration of eighteen electrons, written as $4s^2 4p^6 4d^{10}$. This configuration is favored and stable. It is known as a pseudo-noble-gas configuration.
91. Remind students to use reliable sources and to document their sources. For such an extensive project, it might make sense for students to work in groups and divide up the tasks.

CUMULATIVE REVIEW

95. Organic chemistry is the study of chemicals containing carbon; inorganic chemistry is the study of chemicals that do not contain carbon.
96. an analytical chemist
97. Conserve energy and develop renewable resources.
98. a, b, and d are chemical changes; c is a physical change
99. b and e; c is not a mixture, it is a pure substance
100. **a.** liquid, vapor
b. vapor
c. liquid, vapor
d. liquid, vapor
101. **a.** 56.6 g
b. 0.0048 m
c. 1.81 L
d. 4.0×10^3 mg
102. b
103. –269°C
104. 27.0 cm^3
105. **a.** $^{64}_{30}Zn$ **c.** $^{3}_{1}H$
b. $^{37}_{17}Cl$ **d.** $^{40}_{20}Ca$
106. 14 amu
107. Each of the isotopes has 8 protons and 8 electrons; oxygen-16 also has 8 neutrons, oxygen-17 has 9 neutrons, and oxygen-18 has 10 neutrons.
108. **a.** 1
b. 3
c. 1
d. 5
109. **a.** N, $1s^2 2s^2 2p^3$
b. Be, $1s^2 2s^2$
c. P, $1s^2 2s^2 2p^6 3s^2 3p^2$
d. K, $1s^2 2s^2 2p^6 3s^2 3p^6 4s^1$
110. chlorine, Cl, $1s^2 2s^2 2p^6 3s^2 3p^5$
111 **a.** 5×10^{-7} m
b. the visible region, green
112. **a.** K, $1s^2 2s^2 2p^6 3s^2 3p^6 4s^1$
b. Al, $1s^2 2s^2 2p^6 3s^2 3p^1$
c. S, $1s^2 2s^2 2p^6 3s^2 3p^4$
d. Ba, $1s^2 2s^2 2p^6 3s^2 3p^6 3d^{10} 4s^2 4p^2 4d^{10} 5s^2 5p^6 6s^2$
113. the electron
114. sodium (Na), cesium (Cs), rubidium (Rb), lithium (Li)

Cumulative Review

95. How is organic chemistry distinguished from inorganic chemistry?

96. What is the name given to a chemist who studies the composition of matter?

97. Explain two ways to meet modern society's need for energy.

***98.** Classify the following actions as chemical or physical changes.
a. Cookies are baked.
b. A firefly emits light.
c. A figure is carved from wood.
d. Caramel is made from sugar.

99. Which of the following substances is not a homogeneous mixture?
a. gold ring
b. spaghetti sauce
c. cane sugar
d. window glass
e. river water
f. bottled water

***100.** What physical state(s) can each of the following substances become as you raise its temperature?
a. silver **c.** ice
b. gasoline **d.** wax

101. Round each measurement to the number of significant figures indicated in parentheses.
a. 56.55 g (3) **c.** 1.8072 L (3)
b. 0.004849 m (2) **d.** 4.007×10^3 mg (2)

***102.** Which of the following linear measurements is the longest?
a. 6×10^4 cm **c.** 0.06 km
b. 6×10^6 mm **d.** 6×10^9 nm

103. Helium has a boiling point of 4 K. This is the lowest boiling point of any liquid. Express this temperature in degrees Celsius.

***104.** The density of silicon is 2.33 g/cm^3. What is the volume of a piece of silicon that has a mass of 62.9 g?

105. Express the composition of each atom in shorthand form.
a. zinc-64 **c.** hydrogen-3
b. chlorine-37 **d.** calcium-40

106. An atom of carbon and an atom of element Z together have a mass of 6 amu less than double the mass of an atom of oxygen. If an atom of oxygen has a mass of 16 amu and the mass of an atom of carbon is 12 amu, what is the mass of an atom of element Z?

107. Determine the number of protons, electrons, and neutrons in each of the three isotopes of oxygen.

***108.** How many orbitals are in the following sublevels?
a. 4*s* sublevel **c.** 3*s* sublevel
b. 2*p* sublevel **d.** 4*d* sublevel

109. Give the symbol for each element and write the electron configuration for each atom.
a. nitrogen **c.** phosphorus
b. beryllium **d.** potassium

110. An atom of an element has 17 electrons. Give the name and symbol of the element and write the complete electron configuration.

***111.** A beam of electromagnetic radiation has a wavelength of 500 nm.
a. What is this wavelength in meters?
b. In what region of the spectrum is this?

***112.** Give the symbol of the element and the complete electron configuration of the element found at each location in the periodic table.
a. Group 1A, Period 4
b. Group 3A, Period 3
c. Group 6A, Period 3
d. Group 2A, Period 6

113. Which subatomic particle plays the most important role in chemistry?

114. Give the name and symbol of two elements that have properties similar to those of potassium.

Standardized Test Prep for Indiana

Standard: C.2.6, C.3.3

Select the choice that best answers each question or completes each statement.

Tips for Success

Review All the Answer Choices Even if you find an answer that looks correct, continue reading until you have looked at *every* answer. There may be more than one correct response, or one may be better than another. Also, "all of the above" may be a possible answer. If you stop reading as soon as you find an answer that is correct, you won't notice this option.

1. Which of these is not an ionic compound?
   (A) KF (C) Na_2SO_4
   (B) SiO_2 (D) Na_2O

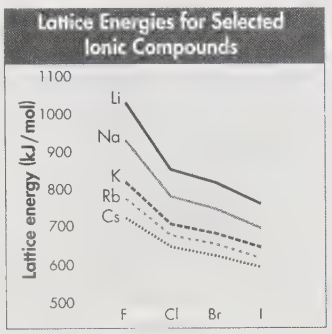
2. Which statements are correct when barium and oxygen react to form an ionic compound?
   I. Each barium atom loses 2 electrons and forms a cation.
   II. Oxygen atoms form oxide anions (O^{2-}).
   III. The ions are present in a one-to-one ratio in the compound.
   (A) I and II only
   (B) II and III only
   (C) I and III only
   (D) I, II, and III

The lettered choices below refer to Questions 3–6. A lettered choice may be used once, more than once, or not at all.

(A) gains two electrons
(B) loses two electrons
(C) gains three electrons
(D) loses one electron
(E) gains one electron

Which choice describes what likely happens as each of the following elements forms an ion?

3. iodine
4. magnesium
5. cesium
6. phosphorus



7. How many valence electrons does arsenic have?
   (A) 5 (C) 3
   (B) 4 (D) 2

8. Which electron configuration represents a nitride ion?
   (A) $1s^2 2s^2 3s^2 4s^2$ (C) $1s^2 2s^2 2p^3$
   (B) $1s^2 2s^2 2p^6$ (D) $1s^2$

9. When a bromine atom gains an electron
   (A) a bromide ion is formed.
   (B) the ion formed has a 1− charge.
   (C) the ion formed is an anion.
   (D) all the above are correct.

Use the description and the graph to answer Questions 10–12.

Lattice energy is the energy required to change one mole (6.02×10^{23} formula units) of a crystalline, ionic solid to gaseous ions. The graph below shows the lattice energies for ionic compounds formed between selected alkali metals and halogens.

10. For a given alkali metal, what is the trend in lattice energy as the atomic radius of the halogen increases?
11. For a given halogen, what is the trend in lattice energy as the atomic radius of the alkali metal increases?
12. Complete this sentence: "As the atomic radius of either the halogen or the alkali metal increases, the lattice energy _____."

Materials List

For the Student

Quick Lab, p 238
- 170-g (6 oz) can of food
- 2 454-g (16 oz) cans of food
- 3 No. 25 rubber bands
- metric ruler
- coat hanger
- plastic grocery bag
- paper clip
- graph paper
- motion detector (optional)

Small-Scale Lab, p 254
- pencil
- ruler
- scissors
- toothpicks
- 4 different colors of food coloring
- plastic cup
- 0.1% NaCl solution
- chromatography paper
- various colored candies
- markers, and powdered drinks
- 70% 2-propanol
- 0.8M CH_3COOH

For the Teacher

Teacher Demo, p 224
- molecular model kit or foam balls and toothpicks

Teacher Demo, p 235
- 10- to 15-cm piece of clean magnesium ribbon
- a small piece of charcoal
- tongs
- Bunsen burner
- filters for viewing

Class Activity, p 249
- magnets
- iron filings
- cardboard

Teacher Demo, p 252
- ring stand
- 2 burets
- 2 beakers
- buret clamps
- turpentine
- water
- rubber rod
- glass rod
- fur cloth

Teacher Demo, p 234
- small piece of copper metal
- concentrated nitric acid
- evaporating dish
- fume hood

Class Activity, p 240
- ball-and-stick molecular model kits or foam balls and toothpicks

Teacher Demo, p 252
- four 300-mL stoppered flasks each containing 100 mL of one of these liquids: glycerol, ethylene glycol, water, ethanol

Online Student Edition
Online Teacher's Edition

What's Online

CHEM TUTOR Students access guided step-by-step tutorials for drawing electron dot structures and distinguishing between various types of chemical bonds.

PROBLEM SETS Students can practice key problem-solving skills in an online problem set.

MATH HELP Identify the students who struggle with math by assigning an online math skills diagnostic test. These students can then improve and practice math skills using the MathXL tutorial system.

VIRTUAL LAB Students go on an animated virtual lab tour in which polar and non-polar molecules are studied in a simulated laboratory environment.

KINETIC ART Students watch animations of selected figures from the chapter followed by questions to check for understanding.

CONCEPTS IN ACTION Students watch an overview of a key chapter concept using real-world contexts and concrete examples and analogies. Each activity includes an interactive animation followed by analysis questions.

Nature of Science

- Use analogies and models (mathematical and physical) to simplify and represent systems that are difficult to understand or directly experience due to their size, time scale, or complexity, and recognize the limitations of analogies and models.

Standard 3: Bonding and Molecular Structure

C.3.1 Describe, compare, and contrast the characteristics of the interactions between atoms in ionic and covalent compounds.

C.3.2 Compare and contrast how ionic and covalent compounds form.

Also covered C.3.3, C.3.4

Focus on ELL

1 CONTENT AND LANGUAGE Write the chapter title on the board. Below the title, write *co-valent bonding*. Ask students to predict the meaning of the title based on what they have learned previously about valence electrons and ionic bonding. Explain that the prefix *co-* means "with" or "together" and the verb *valere* means "to be strong." Explain that this chapter is about the strength of the bond between two electrons that hold together two atoms.

BEGINNING

LOW Create a picture or symbol to represent the phrase. If literate, create a native language definition.

HIGH Write the phrase and introduce it to the class while saying it out loud.

INTERMEDIATE: LOW/HIGH Write simplified English definitions of the phrase and present them to the class.

ADVANCED: LOW/HIGH Write the definition of the phrase and present it to the class.

BIGIDEA

BONDING AND INTERACTIONS

Essential Questions:

1. *How is the bonding in molecular compounds different from the bonding in ionic compounds?*
2. *How do electrons affect the shape of a molecule?*
3. *What factors affect molecular properties?*

CHEMYSTERY

What's That Alarm?

A family woke up in the middle of the night to the sound of a piercing alarm. The family thought it must be the fire alarm. They quickly evacuated the house and called 9-1-1. While they waited for the fire department to arrive, they didn't see smoke or any other signs of fire coming from the house.

The fire department inspected the home and told the family that a compound containing carbon and oxygen atoms caused the alarm. Carbon dioxide (CO_2) is made of carbon and oxygen, but the fire department confirmed that it wasn't carbon dioxide. Are other molecules besides carbon dioxide made of carbon and oxygen? What was this mystery substance, and why would it set off an alarm?

▶ Connect to the BIGIDEA As you read about covalent bonding, think about how there could be different molecules made of carbon and oxygen atoms.

INDIANA'S ACADEMIC STANDARDS FOR SCIENCE

Bonding and Molecular Structure C.3.1, C.3.2, C.3.3, C.3.4. See lessons for details.

Introduce the Chapter

CONNECTIONS TO IONIC BONDING Students have learned about ionic bonds, in which an electrostatic force between oppositely charged atoms holds particles together. Use this activity to introduce the concept of joining atoms together by sharing electrons.

Activity *You will need 2 egg cartons and 14 table tennis balls or balls of modeling clay.* Cut the top off the egg cartons. Then cut away four cups from each egg carton so that each has only 8 cups (a model octet). Give two students each an egg carton. One should have 7 balls with 1 cup empty. The other should have 1 ball with 7 cups empty. **Ask** How can you model the ionic bonding of sodium and chlorine with the balls? *(A chlorine atom has 7 valence electrons, and a sodium atom has 1. The person with 7 balls can take 1 from the other person so that each atom is stable.)* Next, give two other students the egg cartons. Both should have 7 balls and 1 cup empty to model chlorine atoms. **Ask** How can you model bonding with two chlorine atoms? *(Some students may correctly answer that they can each share one of their electrons.)* Guide students to share an "electron." Explain that students have modeled the difference between ionic and covalent bonding.

UbD

Understanding by Design

Students are building toward an understanding of covalent bonding by studying the interaction of particles in compounds.

PERFORMANCE GOALS At the end of Chapter 8, students will be able to answer the essential questions by applying their knowledge of covalent bonding. Students will also understand bond polarity and be able to identify bond type using electronegativities.

ESSENTIAL QUESTIONS Read the essential questions aloud. **Ask** What is a way, other than gaining or losing electrons, that atoms might attain a noble gas configuration? *(sharing electrons)* **Ask** Do you think electrostatic forces will affect the shape of a group of atoms that share electrons? Why? *(Sample answer: Yes. If the pull of an atom is greater, the electron would spend more time near it, affecting the shape of the group.)* **Ask** Can you predict how this might affect the properties of the group of atoms? *(Engage students in a discussion of reasonable answers.)*

BIGIDEA Use the photo of the water drops on a flower to help students connect to the concepts they will learn in this chapter. Activate prior knowledge by reviewing how electrostatic forces among particles cause particles to either attract or repel each other. **Ask** What shape are the water drops? *(round)* **Ask** What forces might hold them in this shape? *(the electrostatic forces among particles)* **Ask** How could the particles of water be attracted to each other if all the particles are alike? *(Different parts of the particles have different charges. This causes one water particle to be attracted to another.)*

CHEMYSTERY Have students read over the CHEMystery. Connect the CHEMystery to the Big Idea of Bonding, Interactions, and Naming Compounds by explaining that bonding can occur among different types of atoms in different ways. For example, a particle of water, H_2O, contains two hydrogen atoms and one oxygen atom. The ratio of hydrogen atoms to oxygen atoms in water is always 2:1. However, hydrogen and oxygen can also combine in other ratios. Have students consider other ratios of carbon and oxygen that might solve the CHEMystery.

LESSON 8.1

Key Objectives

8.1.1 IDENTIFY the information a molecular formula provides.

8.1.2 DESCRIBE the representative units that define molecular compounds and ionic compounds.

Additional Resources

CHEMISTRY & YOU

Q: *How are atoms joined together to make compounds with different structures?* This toy model is made from cubes joined together in units by sticks. Although the types of pieces are limited, you can make many different toy models depending on how many pieces you use and how they are arranged. In this lesson, you will learn how atoms are joined together to form units called molecules.

Key Questions

What information does a molecular formula provide?

What representative units define molecular compounds and ionic compounds?

Vocabulary

- covalent bond
- diatomic molecule
- molecular compound
- molecular formula
- molecule

Molecules and Molecular Compounds

What information does a molecular formula provide?

In nature, only the noble gas elements, such as helium and neon, exist as uncombined atoms. They are monatomic; that is they consist of single atoms, as shown in Figure 8.1. But not all elements are monatomic. For example, a key component of the air you breathe is oxygen gas, O_2. As you might guess from the chemical formula, O_2 represents two oxygen atoms that are bonded together.

In Chapter 7, you learned about ionic compounds, which are generally crystalline solids with high melting points. Other compounds, however, have very different properties. For example, water (H_2O) is a liquid at room temperature. Carbon dioxide (CO_2) and nitrous oxide (N_2O) are both gases at room temperature. The attractions that hold together the atoms in O_2, H_2O, CO_2, and N_2O cannot be explained by ionic bonding. These bonds do not involve the transfer of electrons.

Figure 8.1
Comparing Gas Particles

Helium, which is less dense than air, is often used to inflate balloons.

Scuba divers breathe compressed air, a mixture that contains oxygen gas.

Nitrous oxide (also known as laughing gas) is sometimes used as a mild anesthetic in dental procedures.

Focus on ELL

1 CONTENT AND LANGUAGE As a class, brainstorm the various words that mean the same as *bond*. *(Sample answers: link, union, tie, attachment, connection)* Then have students identify where in this lesson synonyms are used. Then have students identify words that mean the opposite of *bond*. Repeat this exercise with the word *noble*.

2 FRONTLOAD THE LESSON Have students draw a table with column heads labeled *Atoms, Molecules, Diatomic Molecules,* and *Molecular Compounds*. Tell students they will use their tables to organize the names, symbols, and structural drawings of each example illustrated in the lesson.

3 COMPREHENSIBLE INPUT As a class, summarize the paragraph titled Representing Molecules using a two-column table. Under the two column heads labeled *Always True* and *Never True*, construct a list of key points.

Sharing Electrons Recall that ionic bonds form when the combining atoms give up or accept electrons. Another way that atoms can combine is by sharing electrons. Atoms that are held together by sharing electrons are joined by a **covalent bond.** In a covalent bond, a "tug of war" for electrons takes place between the atoms, bonding the atoms together. In Lesson 8.2, you will learn about the different types of covalent bonds.

In Figure 8.1, the representative units shown for oxygen and dinitrogen monoxide are called molecules. A **molecule** is a neutral group of atoms joined together by covalent bonds. Oxygen gas consists of oxygen molecules; each oxygen molecule consists of two covalently bonded oxygen atoms. An oxygen molecule is an example of a **diatomic molecule**—a molecule that contains two atoms. Other elements found in nature in the form of diatomic molecules include hydrogen, nitrogen, and the halogens. Molecules can also be made of atoms of different elements. A compound composed of molecules is called a **molecular compound.** Water is an example of a molecular compound. The molecules in water are all the same; each water molecule is a tightly bound unit of two hydrogen atoms and one oxygen atom.

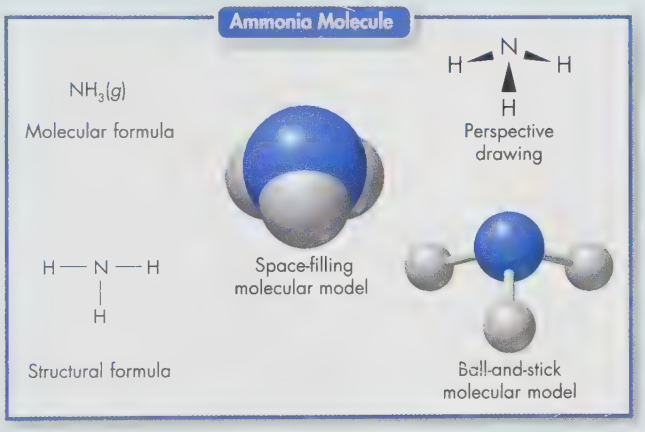

Figure 8.2 Butane
Butane (C_4H_{10}) is commonly used in lighters and household torches. The butane torch shown here is being used to caramelize sugar on a dessert.

Representing Molecules A **molecular formula** is the chemical formula of a molecular compound. **A molecular formula shows how many atoms of each element a substance contains.** The molecular formula of water is H_2O. Notice that a subscript written after an element's symbol indicates the number of atoms of each element in the molecule. If there is only one atom, the subscript 1 is omitted. The molecular formula of carbon dioxide is CO_2. This formula represents a molecule containing one carbon atom and two oxygen atoms.

Butane, shown in Figure 8.2, is also a molecular compound. The molecular formula for butane is C_4H_{10}. According to this formula, one molecule of butane contains four carbon atoms and ten hydrogen atoms. A molecular formula reflects the actual number of atoms in each molecule. The subscripts are not necessarily lowest whole-number ratios. Note that molecular formulas also describe molecules consisting of atoms of one element. For example, an oxygen molecule consists of two oxygen atoms bonded together; its molecular formula is O_2.

A molecular formula does not tell you about a molecule's structure. In other words, it does not show either the arrangement of the various atoms in space or which atoms are covalently bonded to one another. A variety of diagrams and molecular models, some of them illustrated in Figure 8.3, can be used to show the arrangement of atoms in a molecule. Diagrams and models like these will be used throughout this textbook.

Figure 8.3 Representations of an Ammonia Molecule
The formula NH_3 tells you the composition of an ammonia molecule, but it does not reveal the arrangement of the atoms. Molecular models and structural formulas specify the bonds between atoms and the arrangement of those atoms.

Differentiated Instruction

L1 STRUGGLING STUDENTS Prior to introducing molecular compounds, have students practice identifying elements. To help students interpret a molecular compound, have students assign a colored pencil to each element and rewrite the molecular formula using the colored pencils. Have students write the subscript "1" for single atoms in a compound until they comprehend that it is not necessary.

ELL ENGLISH LANGUAGE LEARNERS Prepare three-dimensional models of ammonia similar to the two models in Figure 8.3. Write the molecular and structural formulas for ammonia on large cards. Hold the models and cards up one by one. Slowly and clearly point out the information that each model or formula provides. Have students make their own drawings indicating the key points.

L3 ADVANCED STUDENTS Have students create a poster or models of the various ways that the bonding in a hydrogen molecule can be represented: molecular formula, structural formula, electron-dot structure, and orbital diagram showing the overlap of the 1s orbitals. Then have students research the octet rule and repeat the activity for a chlorine molecule.

Foundations for Reading

BUILD VOCABULARY Explain that the prefix *di-* is a Greek word that means "two." Have students predict the meaning of *diatomic molecule.* *(a molecule containing two atoms)* Have students preview the lesson to verify their prediction. Students should take note of any other words with a common prefix.

READING STRATEGY Encourage students to examine the illustrations carefully as they read. Have students compare the models shown in this lesson with representations of ionic bonding illustrated in Chapter 7. Have students summarize any similarities or differences they notice.

Explain

Molecules and Molecular Compounds

START A CONVERSATION As a class, brainstorm ways in which people join objects together, for instance, attaching papers with a paper clip, attaching a leg of a table to a tabletop with screws, setting a diamond in a ring with prongs, using glue to fix a broken vase, etc. **Ask** What typically guides a person to choose one method for attaching objects over another? *(Sample answers: whether the attachment is permanent or temporary, expensive or inexpensive, etc.)* Guide the discussion toward the concept of stability. Use an analogy involving tape and superglue to help students understand the strength of an ionic or covalent bond. Develop a sense of awareness that the bonding that occurs between two elements varies in strength. Some of the resulting molecules are stronger, meaning more stable, than others. Tell students to keep this in mind as they progress through the chapter.

USE CONTEXT CLUES Have students read the first paragraph. **Ask** What is the meaning of *monatomic*? *(elements that consist of a single atom)* **Ask** Use what you learned about the prefix *di-* from your vocabulary exercise to predict the meaning of the prefix *mono-*. *(one)* Guide students to rely on their language development skills to help them understand difficult or unfamiliar passages.

USING VISUALS Direct students to Figure 8.1. Point out that some other elements are most stable when two atoms are joined together. **Ask** Which of the three examples are monatomic molecules? *(helium)* **Ask** Is H_2 a monatomic or diatomic molecule? *(diatomic molecule)* **Ask** Do you think H_2 could be an ionic compound? *(No, ionic bonds do not form between two atoms of the same element.)* Tell students that H_2 is a molecule held together not by the transfer of an electron but by the sharing of a pair of electrons.

Explain

USE AN ANALOGY Point out that the recipe for a cake provides information about what type and how much of each ingredient is needed. Varying the types and amounts of ingredients leads to cakes that have different tastes and textures. **Ask** How does a molecular formula provide similar information about a compound? *(The subscripts in a molecular formula tell the number of atoms of each element in a compound.)*

Misconception Alert

Students often confuse empirical (simplest) formulas and molecular formulas. Explain that the subscripts in a molecular formula are not necessarily written in the smallest whole-number ratio of the atoms. For example, ethane is correctly represented by the formula C_2H_6 because the molecule actually contains two carbon atoms and six hydrogen atoms. It would be incorrect to represent ethane by its empirical formula, which is CH_3.

CHEMISTRY & YOU Atoms join together by forming covalent bonds. Changing the number, type, and/or order of the atoms changes the compound. Atoms can also be joined by ionic bonds.

Explore

TeacherDemo

PURPOSE Students see the structure associated with molecular formulas.

MATERIALS molecular model kit or foam balls and toothpicks

PROCEDURE Construct models of these pairs of molecules: O_2 and O_3; CO and CO_2; H_2O and H_2O_2. Show students each pair and ask them how many of each type of atom is in each molecule. Write the corresponding chemical formulas on the chalkboard.

EXPECTED OUTCOMES Students will see that the addition of one more oxygen atom to O_2, CO, and H_2O results in new molecules that have very different structures.

Explain

Comparing Molecular and Ionic Compounds

USE VISUALS Direct students to examine Figure 8.5. **Ask** How do the submicroscopic illustrations of NaCl and H_2O differ? *(The ions of sodium and chlorine are separate and arrayed in a regular pattern; two hydrogen atoms and one oxygen atom are bonded together in one molecule.)* Compare the formulas for NaCl and H_2O. *(They look similar, but NaCl represents just one unit in the array of sodium and chloride ions, whereas H_2O represents one separate molecule of water.)*

Figure 8.4
Molecular Formulas and Structures
The formula of a molecular compound indicates the numbers and kinds of atoms in each molecule of the compound.
Use Models ***Which of these molecules has the greatest number of oxygen atoms?***

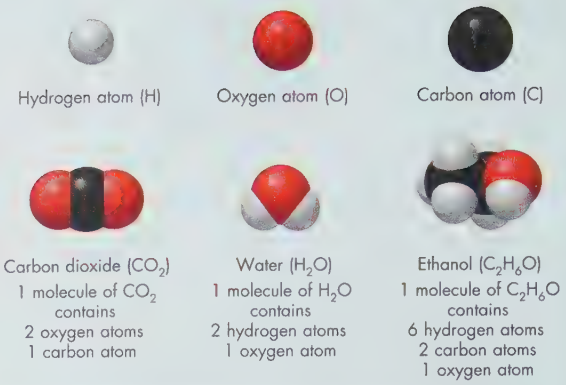

Figure 8.4 shows the chemical formulas and structures of some other molecular compounds. The arrangement of the atoms within a molecule is called its molecular structure. Carbon dioxide, for example, is a gas produced by the complete burning of carbon. It is found in Earth's atmosphere and is dissolved in seawater. The molecular structure of carbon dioxide shows how the three atoms are arranged in a row. It also shows how the carbon atom in each molecule is in the middle between the two oxygen atoms. The molecular structure of water shows how the oxygen atom is in the middle between the hydrogen atoms. However, the atoms in water are not arranged in a row. Instead, the hydrogen atoms are mainly on one side of the water molecule. The molecular structure of ethanol (C_2H_6O) is more complicated. As you can see in the model, each carbon is bonded to four atoms, each hydrogen is bonded to one atom, and the one oxygen is bonded to two atoms.

CHEMISTRY & YOU

Q: *Similar to how you can make different types of toy models, there are thousands of different types of molecular structures. How are atoms joined together to make compounds with different structures?*

Comparing Molecular and Ionic Compounds

What representative units define molecular compounds and ionic compounds?

You have now seen how formulas can be used to describe molecular compounds and ionic compounds. Each type of compound contains atoms of different elements that are combined chemically. However, the formulas describe different representative units. **The representative unit of a molecular compound is a molecule. For an ionic compound, the representative unit is a formula unit.** Recall that a formula unit is the lowest whole-number ratio of ions in an ionic compound. It is important not to confuse formula units with molecules. A molecule is made up of two or more atoms that act as a unit. No such discrete units exist in an ionic compound, which consists of a continuous array of ions. So there is no such thing as a molecule of sodium chloride or a molecule of magnesium chloride. Instead, these compounds exist as collections of positively and negatively charged ions arranged in repeating three-dimensional patterns.

UbD Check for Understanding

BIGIDEA **BONDING AND INTERACTIONS** Give each student an index card. Assess students' knowledge of how bonding in molecular compounds differs from bonding in ionic compounds. Ask students to state the type of compound associated with electron sharing, and the type of compound associated with electron transfer. *(molecular compound; ionic compound)*

ADJUST INSTRUCTION If students are having difficulty answering the question, have them re-read the previous page and then repeat the exercise.

Molecular compounds tend to have relatively lower melting and boiling points than ionic compounds. Many molecular compounds are gases or liquids at room temperature. In contrast to ionic compounds, which are formed from a metal combined with a nonmetal, most molecular compounds are composed of atoms of two or more nonmetals. For example, one atom of carbon can combine with one atom of oxygen to produce one molecule of a compound known as carbon monoxide. Carbon monoxide is a poisonous gas produced by burning gasoline in internal combustion engines or in household gas appliances and furnaces. Figure 8.5 illustrates some differences between molecular and ionic compounds, using water and sodium chloride as examples.

Figure 8.5 Molecular and Ionic Compounds Water, which is a molecular compound, and sodium chloride, which is an ionic compound, are compared here.
Interpret Diagrams ***How do molecular compounds differ from ionic compounds?***

8.1 LessonCheck

1. **Identify** What information does a molecular formula provide?
2. **Compare** How is the representative unit of a molecular compound different from the representative unit of an ionic compound?
3. **Identify** What are the only elements that exist in nature as uncombined atoms? What term is used to describe such elements?
4. **Compare and Contrast** Describe how the molecule whose formula is NO is different from the molecule whose formula is N_2O.
5. **Apply Concepts** Give an example of a diatomic molecule found in Earth's atmosphere.
6. **Identify** What information does a molecular structure give?

Lesson Check Answers

1. Molecular formulas show how many atoms of each element one molecule of a compound contains.
2. The representative unit of a molecular compound is a molecule. The representative unit of an ionic compound is a formula unit.
3. noble gases; monatomic
4. NO has 1 N atom and 1 O atom; N_2O has 2 N atoms and 1 O atom.
5. nitrogen (N_2) or oxygen (O_2)
6. Molecular structures show the arrangement of atoms in a molecule.

CRITICAL THINKING Have students explain why two hydrogen atoms bond by sharing rather than by electron transfer to form a hydrogen molecule. *(Hydrogen atoms cannot transfer electrons, so there is no way to determine which hydrogen atom would donate and which would receive an electron. However, if the hydrogen atoms share their electrons, they can each achieve the stable arrangement of a helium atom.)*

Evaluate

Informal Assessment

Have students number a sheet of paper from 1 to 6. Write the following statements on the board. Have students indicate on their papers if the following statements are true or false:

1. All molecular compounds are composed of atoms of two or more different elements. *(true)*
2. All compounds contain molecules. *(false)*
3. No elements exist as molecules. *(false)*
4. Most molecular compounds are composed of two or more nonmetallic elements. *(true)*
5. Atoms in molecular compounds share electrons. *(true)*
6. Ionic compounds tend to have lower melting and boiling points than molecular compounds. *(false)*

Then have students complete the 8.1 Lesson Check.

Reteach

Use the statements in the Informal Assessment above as a basis for review. Have students locate where in the lesson the concept for each statement is explained. Use the given material to prove each statement as true or provide an example to show that the statement is false.

Answers

FIGURE 8.4 carbon dioxide
FIGURE 8.5 Molecular compounds are made up of molecules and usually have lower melting and boiling points than ionic compounds, which are made up of ions.

LESSON 8.2

Key Objectives

- **8.2.1 EXPLAIN** the result of electron sharing in covalent bonds.
- **8.2.2 DESCRIBE** how coordinate covalent bonds are different from other covalent bonds.
- **8.2.3 IDENTIFY** some exceptions to the octet rule.
- **8.2.4 EXPLAIN** how the strength of a covalent bond is related to its bond dissociation energy.
- **8.2.5 DESCRIBE** the how resonance structures are used.

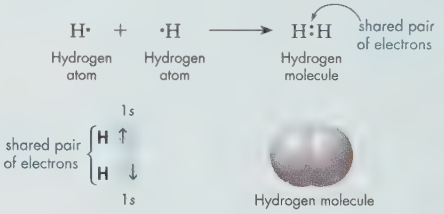
CHEMISTRY & YOU

Q: *What is the difference between the oxygen you breathe and the oxygen in ozone in the atmosphere?* Our atmosphere contains two different molecules that are both made of oxygen atoms. One is the oxygen that our cells need to survive. The other molecule containing only oxygen atoms is the ozone that protects us from the sun but also contributes to smog. The colors in this map indicate the concentrations of ozone in various parts of Earth's atmosphere. In this lesson, you will learn how oxygen atoms can join to form the oxygen you breathe and can also join to form ozone.

Key Questions

- *What is the result of electron sharing in covalent bonds?*
- *How are coordinate covalent bonds different from other covalent bonds?*
- *What are some exceptions to the octet rule?*
- *How is the strength of a covalent bond related to its bond dissociation energy?*
- *How are resonance structures used?*

Vocabulary



- single covalent bond
- structural formula
- unshared pair
- double covalent bond
- triple covalent bond
- coordinate covalent bond
- polyatomic ion
- bond dissociation energy
- resonance structure

The Octet Rule in Covalent Bonding

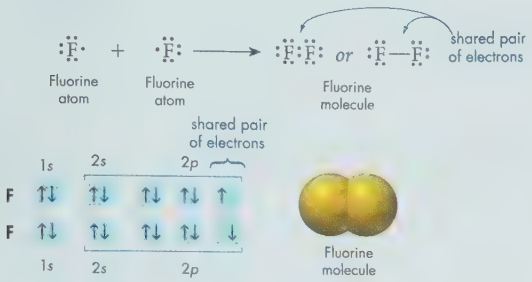
What is the result of electron sharing in covalent bonds?

Recall that when ionic compounds form, electrons tend to be transferred so that each ion acquires a noble gas configuration. A similar rule applies for covalent bonds. **In covalent bonds, electron sharing usually occurs so that atoms attain the electron configurations of noble gases.** For example, a single hydrogen atom has one electron. But a pair of hydrogen atoms shares electrons to form a covalent bond in a diatomic hydrogen molecule. Each hydrogen atom, thus, attains the electron configuration of helium, a noble gas with two electrons. Combinations of atoms of the nonmetals and metalloids in Groups 4A, 5A, 6A, and 7A of the periodic table are likely to form covalent bonds. The combined atoms usually acquire a total of eight electrons, or an octet, by sharing electrons, so that the octet rule applies.

Single Covalent Bonds The hydrogen atoms in a hydrogen molecule are held together mainly by the attraction of the shared electrons to the positive nuclei. Two atoms held together by sharing one pair of electrons are joined by a **single covalent bond.** Hydrogen gas consists of diatomic molecules whose atoms share only one pair of electrons, forming a single covalent bond.

Focus on ELL

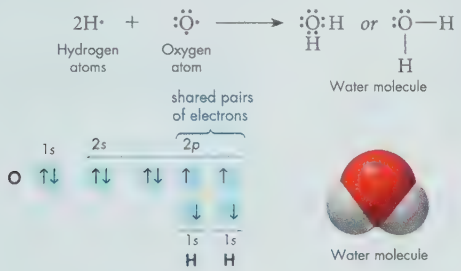
1 CONTENT AND LANGUAGE Have each student prepare a set of flash cards for the vocabulary words in this lesson. Each card should list the vocabulary word, its definition, and the page number where it can be found. Cycle through the index cards a few times, reading the words aloud as a class. Point out familiar prefixes, *poly-* and *dis-* and *co-*, and remind students of their meanings. *(many; not; with or together)*



2 FRONTLOAD THE LESSON Divide the class into three groups. Have one group preview all the models in the lesson; another group, the tables, charts, and photos; and the third, the sample problems. Ask each group to answer a series of questions, such as *What is this lesson about? Is there anything I have already learned that will help me learn this material?* Have each group present their answers to the class, as well as any symbols or vocabulary that is unfamiliar.

3 COMPREHENSIBLE INPUT Re-draw the electron dot figures used throughout lesson 8.2, using a separate color for each different element's electrons to help demonstrate the concepts associated with each figure. Have students view the Kinetic Art animation of covalent bonding.

An electron dot structure such as H:H represents the shared pair of electrons of the covalent bond by two dots. The pair of shared electrons forming the covalent bond is also often represented as a dash, as in H—H for hydrogen. A **structural formula** represents the covalent bonds as dashes and shows the arrangement of covalently bonded atoms. In contrast, the molecular formula of hydrogen, H_2, indicates only the number of hydrogen atoms in each molecule.



See covalent bonding animated online. KINETIC ART

The halogens also form single covalent bonds in their diatomic molecules. Fluorine is one example. Because a fluorine atom has seven valence electrons, it needs one more to attain the electron configuration of a noble gas. By sharing electrons and forming a single covalent bond, two fluorine atoms each achieve the electron configuration of neon.

In the F_2 molecule, each fluorine atom contributes one electron to complete the octet. Notice that the two fluorine atoms share only one pair of valence electrons. A pair of valence electrons that is not shared between atoms is called an **unshared pair,** also known as a lone pair or a nonbonding pair. In F_2, each fluorine atom has three unshared pairs of electrons.

You can draw electron dot structures for molecules of compounds in much the same way that you draw them for molecules of diatomic elements. Water (H_2O) is a molecule containing three atoms with two single covalent bonds. Two hydrogen atoms share electrons with one oxygen atom. The hydrogen and oxygen atoms attain noble-gas configurations by sharing electrons. As you can see in the electron dot structures below, the oxygen atom in water has two unshared pairs of valence electrons.

Differentiated Instruction

L1 STRUGGLING STUDENTS Pair each student with a study partner. Have them use the periodic table and quiz each other on writing electron dot structures for single atoms and bonded atoms. Make sure they understand that for groups 1, 2, and 13–18, the number in the ones place indicates the number of valence electrons that atom has, and that it is valence electrons that appear in the electron dot structures.

L1 SPECIAL NEEDS Recreate the electron dot structures on large posters or overheads. Show students with a colored marker how to draw the dots. Point out where on the periodic table the element is located; circle the element and circle the group number. Then explain the reasoning for the placement and the number of dots. Make sure the noble gas group on their periodic table is highlighted.

Foundations for Reading

BUILD VOCABULARY Explain that the word *structure* comes from the Latin verb *struere*, which means "to build." Convey that a structural formula is one that shows how the atoms of a molecule are joined together by chemical bonds.

READING STRATEGY Identify the main idea in the paragraph titled The Octet Rule in Covalent Bonding. Have students create and complete a KWL chart, with corresponding examples, to support how this rule is applied to a single covalent bond, a double covalent bond, and a triple covalent bond.

Explain

The Octet Rule in Covalent Bonding

APPLY CONCEPTS Write electron configurations for carbon, nitrogen, oxygen, fluorine, and neon on the chalkboard. **Ask** How many electrons would carbon, nitrogen, oxygen, and fluorine need to share in order to achieve the same electron configuration as neon? *(4, 3, 2, and 1, respectively)*

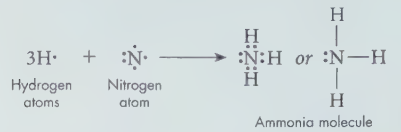
Explore

Class Activity

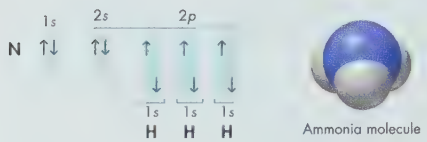
PURPOSE Students practice different ways to represent molecules.

MATERIALS paper and pencil

PROCEDURE Divide students into groups of three or four. Have them practice drawing molecular diagrams, structural formulas, electron-dot structures, and orbital diagrams for molecules such as OF_2, SCl_2, N_2H_4, CCl_4, $CHCl_3$, and C_2H_6.

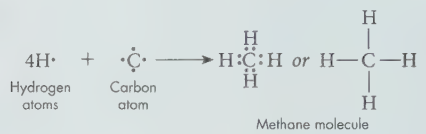


Explain



INTERPRET DIAGRAMS Direct students to examine the molecular and structural formulas, electron dot structures, and orbital diagrams for the ammonia molecule and compare it to the fluorine and water examples on the previous page. If possible, display physical models. Call attention to the fact that fluorine has one half-filled orbital and forms one bond, oxygen has two half-filled orbitals and forms two bonds, and nitrogen has three and forms three bonds.

MAKE A CONNECTION Direct students to examine the molecular and structural formulas, electron dot structures, and orbital diagrams for the methane molecule. Tell students that carbon has two half-filled orbitals. **Ask** How many covalent bonds do you think carbon forms? *(Students may logically say* two.*)* Tell students that CH_2 does not represent a stable molecule, but CH_4, methane, is a stable molecule. Explain the concept of electron promotion, which allows carbon to form four single covalent bonds.



CRITICAL THINKING Expand on the concept of electron promotion by showing students that elements in groups 13 and 14 of the periodic table promote *s* electrons to *p* orbitals, increasing their bonding capacity. Point out that boron's electron configuration is $1s^2 2s^2 2p^1$. **Ask** Based on this configuration, how many covalent bonds do you think boron forms? *(Students may logically say* one.*)* Have students explain how it is possible for the chloride of boron to be BCl_3 rather than BCl. *(The promotion of one 2s electron to the 2p orbital allows for the formation of three bonds.)* **Ask** Since boron does not achieve a noble gas configuration, how does it achieve stability? *(It forms added stability by forming three bonds rather than one.)*

You can draw the electron dot structure for ammonia (NH_3), a suffocating gas, in a similar way. The ammonia molecule has one unshared pair of electrons.

The stove in Figure 8.6 is fueled by natural gas. The principal component of natural gas is methane (CH_4). Methane contains four single covalent bonds. The carbon atom has four valence electrons and needs four more valence electrons to attain a noble-gas configuration. Each of the four hydrogen atoms contributes one electron to share with the carbon atom, forming four identical carbon-hydrogen bonds. As you can see in the electron dot structure below, methane has no unshared pairs of electrons.

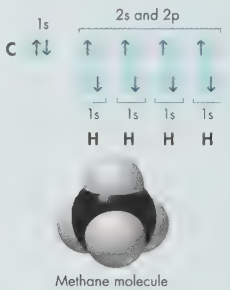


Figure 8.6 Methane
Methane is the principal component of natural gas. Natural gas is commonly used as a fuel for household gas appliances such as gas stoves, water heaters, dryers, and furnaces.

When carbon forms bonds with other atoms, it usually forms four bonds, as in methane. You would not predict this pattern based on carbon's electron configuration, shown below.

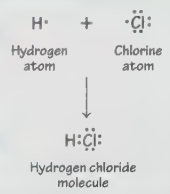
Expanding the Octet

Nonmetals in the third row and beyond, such as phosphorus, sulfur, and iodine, can form more than four bonds because they have empty *d* orbitals. Phosphorus, for example, can unpair a 3*s* electron and promote it to an empty 3*d* orbital. The promotion allows phosphorus to form five bonds. The amount of energy needed to promote an electron is less than the energy released with the formation of an extra bond. Sulfur can promote one 3*s* electron and one 3*p* electron and form two extra bonds.

If you tried to form covalent C—H bonds for methane by combining the two 2*p* electrons of the carbon with two 1*s* electrons of hydrogen atoms, you would incorrectly predict a molecule with the formula CH_2 (instead of CH_4). The formation of four bonds by carbon can be explained by the fact that one of carbon's 2*s* electrons is promoted to the vacant 2*p* orbital to form the following electron configuration:

This electron promotion requires only a small amount of energy. The promotion provides four electrons of carbon that are capable of forming covalent bonds with four hydrogen atoms. Methane, the carbon compound formed by electron sharing of carbon with four hydrogen atoms, is much more stable than CH_2. The stability of the resulting methane more than compensates for the small energy cost of the electron promotion. Therefore, formation of methane (CH_4) is more energetically favored than the formation of CH_2.

SampleProblem 8.1



Drawing an Electron Dot Structure

Hydrochloric acid (HCl (*aq*)) is prepared by dissolving gaseous hydrogen chloride (HCl (*g*)) in water. Hydrogen chloride is a diatomic molecule with a single covalent bond. Draw the electron dot structure for HCl.

1 Analyze **Identify the relevant concepts.** In a single covalent bond, a hydrogen and a chlorine atom must share a pair of electrons. Each must contribute one electron to the bond. Then show the electron sharing in the compound they produce.

2 Solve **Apply concepts to the problem.**

Draw the electron dot structures for the hydrogen and chlorine atoms.

Draw the electron dot structure for the hydrogen chloride molecule.

Through electron sharing, the hydrogen and chlorine atoms attain the electron configurations of the noble gases helium and argon, respectively.

7. Draw electron dot structures for each molecule.
- **a.** chlorine
- **b.** bromine
- **c.** iodine

8. The following molecules have single covalent bonds. Draw an electron dot structure for each.
- **a.** H_2O_2
- **b.** PCl_3

UbD Check for Understanding

What is the result of electron sharing in covalent bonds?

Assess students' understanding of electron sharing in covalent bonds by asking them to answer the key question in two sentences or less, using their own words. *(Sample answer: Atoms share electrons in order to form an octet. The result is a stable molecule.)*

ADJUST INSTRUCTION If students are having difficulty writing their summaries, review the differences between ionic and covalent compounds. Point out that ions gain or lose electrons to achieve an ionic compound with a noble gas configuration, whereas atoms share electrons to achieve a molecular compound with a noble gas configuration.

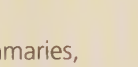
Explore

Class Activity

PURPOSE Students gain understanding of covalent bonding and distinguish between covalent and ionic bonding.

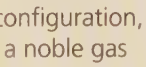
PROCEDURE Have students draw electron dot structures for each element in the second row of the periodic table: Li, Be, B, C, N, O, and F. Then have them answer the following:

- Predict how many bonds each atom must form to attain a noble gas configuration. *(1, 2, 3, 4, 3, 2, 1)*
- Can lithium form a covalent bond and reach stability? *(no)*
- Which elements can reach stability by forming covalent bonds? *(C, N, O, F)*
- Can fluorine form an ionic bond? *(yes)*
- Are the bonds in nitrogen molecules, N_2, ionic or covalent? *(covalent)*



Sample Practice Problem

The following covalent molecules have only single covalent bonds. Draw an electron dot structure for each.



a. NF_3

b. SBr_2

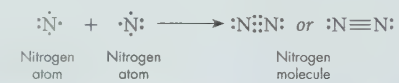
Explain

START A CONVERSATION To introduce the discussion of multiple covalent bonds, use the electron dot structure for the nitrogen molecule. **Ask** How does the structure of diatomic nitrogen satisfy the octet rule? *(The nitrogen atoms can share six electrons.)* Have students compare the bonding in ammonia with the bonding in nitrogen gas. Then introduce the oxygen molecule. Instruct students to draw a structure that obeys the octet rule. **Ask** Why doesn't oxygen form a triple bond? *(Each oxygen atom needs to share only two electrons to achieve a stable electron configuration.)* Explain that although a double bond in the oxygen molecule fulfills the octet rule, it does not fit with experimental evidence that shows that the oxygen molecule contains two unpaired electrons. Thus the structure of O_2 is an exception to the octet rule.

USE MODELS Help students draw the electron dot structure and orbital diagram for carbon dioxide. **Ask** What type of bonds does carbon form with the two oxygen atoms in CO_2? *(double covalent bonds)* Note that carbon can form single, double, and triple bonds, but a quadruple bond is impossible because of geometric restrictions. Have students draw diagrams for hydrogen cyanide (HCN) and formaldehyde (H_2CO). **Ask** What kind of bonds does carbon form in each of these molecules? *(HCN: one single carbon-to-hydrogen bond and one triple carbon-to-nitrogen bond; H_2CO: two single carbon-to-hydrogen bonds and one double carbon-to-oxygen bond)* As the discussion proceeds, provide models for the molecules discussed, or allow students time to come up with a way to model the examples with materials in the classroom or home.

Figure 8.7 Carbon Dioxide
Carbon dioxide gas is soluble in water and is used to carbonate many beverages. A carbon dioxide molecule has two carbon–oxygen double bonds.

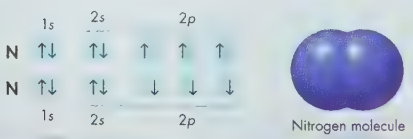
Double and Triple Covalent Bonds Sometimes atoms bond by sharing more than one pair of electrons. **Atoms form double or triple covalent bonds if they can attain a noble gas structure by sharing two pairs or three pairs of electrons.** A **double covalent bond** is a bond that involves two shared pairs of electrons. Similarly, a bond formed by sharing three pairs of electrons is a **triple covalent bond.**



Carbon dioxide (CO_2) is used to carbonate many soft drinks like the one shown in Figure 8.7. The carbon dioxide molecule contains two oxygens, each of which shares two electrons with carbon to form a total of two carbon–oxygen double bonds.

The two double bonds in the carbon dioxide molecule are identical to each other. Carbon dioxide is an example of a triatomic molecule, which is a molecule consisting of three atoms.

An example of an element whose molecules contain triple bonds is nitrogen (N_2), a major component of Earth's atmosphere, illustrated in Figure 8.8. A single nitrogen atom has five valence electrons. Each nitrogen atom in the nitrogen molecule must share three electrons to have the electron configuration of neon. In the nitrogen molecule, each nitrogen atom has one unshared pair of electrons.



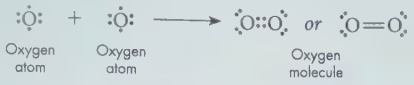


Figure 8.8
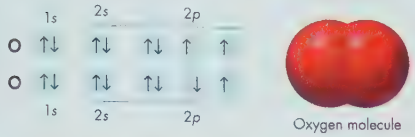
Oxygen and Nitrogen
Oxygen and nitrogen are the main components of Earth's atmosphere. The oxygen molecule is an exception to the octet rule. It has two unpaired electrons. Three pairs of electrons are shared in a nitrogen molecule.



Professional Development Note

Inventing Electron Dot Structures

Gilbert Newton Lewis (1875–1946) was an American chemist who invented electron dot structures, which are often called Lewis structures or diagrams in his honor. These structures supported Lewis's theory of the electron pair in chemical bonding. As a professor of physical chemistry, he expanded the theory of acids and bases by defining an acid as an electron pair acceptor and a base as an electron pair donor. The definitions encompass all Brønsted-Lowry acid-base reactions and include many others not previously categorized as acid-base reactions.

You might think that an oxygen atom, with six valence electrons, would form a double bond by sharing two of its electrons with another oxygen atom.

Oxygen molecule

In such an arrangement, all the electrons within the molecule would be paired. Experimental evidence, however, indicates that two of the electrons in O_2 are still unpaired. Thus, the bonding in the oxygen molecule (O_2) does not obey the octet rule. You cannot draw an electron dot structure that adequately describes the bonding in the oxygen molecule.

Nitrogen and oxygen are both diatomic molecules. Table 8.1 lists the properties and uses of these elements and some others that exist as diatomic molecules.

Table 8.1

The Diatomic Elements

Name	Chemical formula	Electron dot structure	Properties and uses
Fluorine	F_2	:F—F:	Greenish-yellow reactive toxic gas. Compounds of fluorine, a halogen, are added to drinking water and toothpaste to promote healthy teeth.
Chlorine	Cl_2	:Cl—Cl:	Greenish-yellow reactive toxic gas. Chlorine is a halogen used in household bleaching agents.
Bromine	Br_2	:Br—Br:	Dense red-brown liquid with pungent odor. Compounds of bromine, a halogen, are used in the preparation of photographic emulsions.
Iodine	I_2	:I—I:	Dense gray-black solid that produces purple vapors; a halogen. A solution of iodine in alcohol (tincture of iodine) is used as an antiseptic.
Hydrogen	H_2	H—H	Colorless, odorless, tasteless gas. Hydrogen is the lightest known element.
Nitrogen	N_2	:N≡N:	Colorless, odorless, tasteless gas. Air is almost 80% nitrogen by volume.
Oxygen	O_2	Inadequate	Colorless, odorless, tasteless gas that is vital for life. Air is about 20% oxygen by volume.

Differentiated Instruction

LPR LESS PROFICIENT READERS Divide students into groups of three or four. Have them draw electron dot formulas for oxygen and fluorine, then combine the drawings into the electron dot formula for OF_2. Have them do the same for SCl_2 and CCl_4. When students have mastered these, continue the exercise with $CHCl_3$, N_2H_4, and C_2H_6.

ELL ENGLISH LANGUAGE LEARNERS Provide a step-by-step process for creating electron dot structures. Include a step for checking that each element has four pairs of electrons around it. Have students draw a circle around each element that has a full octet. Relate the word *octet* to *octopus* and *octagon*, to help students remember that it refers to 8 electrons.

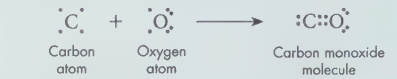
L3 ADVANCED STUDENTS Have students research or discover elements and compounds with atoms that do not follow the octet rule. *(Sample answers: Be, Al, P, NO_2, PF_5)*

Explain

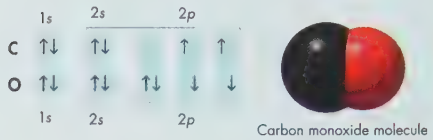
MAKE A CONNECTION Explain to the class that Earth's atmosphere is approximately 80 percent nitrogen gas. However, surprisingly few nitrogen compounds exist compared with the numerous compounds of oxygen, which constitutes only 20 percent of the atmosphere. Students may correctly surmise that the triple bond in N_2 is harder to break than a double bond and considerably harder to break than a single bond. Thus, N_2 is a stable molecule. Explain that plant and animal life depends on nitrogen, but in order to be usable to living systems, the element must be converted to a compound. Point out that this process is called nitrogen fixation. Tell students that nitrogen fixation occurs naturally when lightning provides the energy for atmospheric nitrogen to react with oxygen to form nitrogen oxides. The oxides dissolve in rain and fall to the ground where they can be utilized by plants. Nitrogen-fixing bacteria in the soil are also able to convert atmospheric nitrogen to usable compounds.

Explain

Coordinate Covalent Bonds

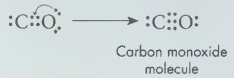


APPLY CONCEPTS Explain that a coordinate covalent bond is an exception to the rule that covalent bonding occurs between two half-empty orbitals of two atoms. Show students that in a coordinate covalent bond, one atom has an empty orbital and the other, an orbital filled with an electron pair that is not yet involved in a chemical bond. Note that the bonding still involves only one pair of electrons and one pair of orbitals, but one atom provides both of the shared electrons.



CRITICAL THINKING Ask students to compare the electron dot structure for ammonia, NH_3, and for a hydrogen ion, H^+. After forming the three nitrogen-to-hydrogen bonds, nitrogen has an unshared pair of electrons. The hydrogen ion has no electrons available for bonding. **Ask** How do you explain the existence of the ammonium ion, NH_4^+? *(The empty orbital of the H^+ must overlap the filled orbital in ammonia. The electrons from nitrogen are attracted to both the nitrogen nucleus and the hydrogen nucleus. A bond forms when electrons are simultaneously attracted to two nuclei. This type of bond is called a coordinate covalent bond.)*

Coordinate Covalent Bonds



How are coordinate covalent bonds different from other covalent bonds?

Carbon monoxide (CO) is an example of a type of covalent bonding different from that seen in water, ammonia, methane, and carbon dioxide. A carbon atom needs to gain four electrons to attain the electron configuration of neon. An oxygen atom needs two electrons. Yet it is possible for both atoms to achieve noble-gas electron configurations by a type of bonding called coordinate covalent bonding. To see how, begin by looking at the double covalent bond between carbon and oxygen.

With the double bond in place, the oxygen has a stable configuration, but the carbon does not. As shown below, the dilemma is solved if the oxygen also donates one of its unshared pairs of electrons for bonding.

A covalent bond in which one atom contributes both bonding electrons is a **coordinate covalent bond.** In a structural formula, you can show coordinate covalent bonds as arrows that point from the atom donating the pair of electrons to the atom receiving them. The structural formula of carbon monoxide, with two covalent bonds and one coordinate covalent bond, is C≡O. **In a coordinate covalent bond, the shared electron pair comes from one of the bonding atoms.** Once formed, a coordinate covalent bond is like any other covalent bond.

The ammonium ion (NH_4^+), which is often found in fertilizers like the one in Figure 8.9, consists of atoms joined by covalent bonds, including a coordinate covalent bond. A **polyatomic ion,** such as NH_4^+, is a tightly bound group of atoms that has a positive or negative charge and behaves as a unit. The ammonium ion forms when a positively charged hydrogen ion (H^+) attaches to the unshared electron pair of an ammonia molecule (NH_3).

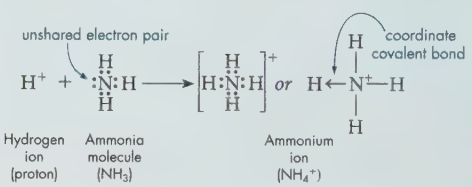


Figure 8.9 Ammonia Fertilizers
Most plants need nitrogen that is already combined in a compound rather than molecular nitrogen (N_2) to grow. The polyatomic ammonium ion (NH_4^+), present in ammonium hydroxide, also called aqua ammonia, is an important component of fertilizer for field crops, home gardens, and potted plants.

UbD Check for Understanding

How are coordinate covalent bonds different from other covalent bonds?

Assess students' understanding of coordinate covalent bonds by having them write a one-minute response that explains the bonding in CO_2 and then explains the bonding in CO using coordinate covalent bonding.

ADJUST INSTRUCTION If students are having difficulty understanding the difference between normal covalent bonding and coordinate covalent bonding, construct a model of each element. Then construct a model of each compound to give students a visual image of the difference in how the electrons are shared.

Most polyatomic cations and anions contain covalent and coordinate covalent bonds. Therefore, compounds containing polyatomic ions include both ionic and covalent bonding. As another example, draw the electron dot structure of the polyatomic ion SO_3^{2-}. First, draw the electron dot structures for the oxygen and sulfur atoms, and the two extra electrons indicated by the charge. Then, join two of the oxygens to sulfur by single covalent bonds.

Remember, the charge of a negative polyatomic ion is equal to the number of electrons that are in addition to the valence electrons of the atoms present. Since a negatively charged polyatomic ion is part of an ionic compound, the positive charge of the cation of the compound balances the additional electrons.

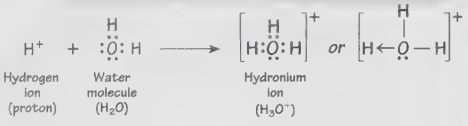
Next, join the remaining oxygen by a coordinate covalent bond, with sulfur donating one of its unshared pairs to oxygen, and add the two extra electrons. Put brackets around the structure and indicate the 2− charge.

Each of the atoms now has eight valence electrons, satisfying the octet rule. Without the extra electrons, two of the oxygens would be electron-deficient.

Table 8.2 lists electron dot structures of some common compounds with covalent bonds.

SampleProblem 8.2

Drawing the Electron Dot Structure of a Polyatomic Ion



The H_3O^+ ion forms when a hydrogen ion is attracted to an unshared electron pair in a water molecule. Draw the electron dot structure of the hydronium ion.

1 Analyze **Identify the relevant concepts.** Each atom must share electrons to satisfy the octet rule.

2 Solve **Apply the concepts to the problem.**

Remember to always include the charge when drawing electron dot structures of polyatomic ions.

Draw the electron dot structure of the water molecule and the hydrogen ion. Then, draw the electron dot structure of the hydronium ion. The oxygen must share a pair of electrons with the added hydrogen ion to form a coordinate covalent bond.

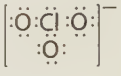
Check that all the atoms have the electrons they need and that the charge is correct.

The oxygen in the hydronium ion has eight valence electrons, and each hydrogen shares two valence electrons, satisfying the octet rule. The water molecule is neutral, and the hydrogen ion has a positive charge, giving the hydronium ion a charge of 1+.

9. Draw the electron dot structure of the hydroxide ion (OH^-).

10. Draw the electron dot structures for sulfate (SO_4^{2-}) and carbonate (CO_3^{2-}). Sulfur and carbon are the central atoms, respectively.

Foundations For Math



PATTERNS Students may start to realize that an element's electron configuration and its location in the periodic table has a useful relationship. Guide students to realize that the number of bonds typically formed by atoms in a covalent compound is equal to the atom's number of valence shell electrons that the atom must gain or lose in order to achieve an octet.

In **Sample Problem 8.2,** as well as in other examples in this lesson, the number of valence electrons equals the number in the ones column of the Group number. Have students note this pattern on their periodic table and encourage students to continue to look for these types of patterns as they work through this chapter.

APPLY CONCEPTS Have students write the electron dot structure for SO_2. Emphasize that the structure should satisfy the bonding requirements of all three atoms. Students should find that, to satisfy the octet rule for all the atoms, they must write a structure in which one oxygen atom is double bonded to sulfur. The other oxygen is single bonded by a coordinate covalent bond in which the electrons are donated by sulfur. Point out that experimental evidence indicates that both sulfur-oxygen bonds are identical. Explain that this evidence indicates that the bonding in SO_2 must be some intermediate between a single and double bond. **Ask** How does the formation of a coordinate covalent bond differ from that of a covalent bond? *(In a covalent bond, each atom provides one electon. In a coordinate covalent bond, both electrons are provided by the same atom.)*

Sample Practice Problem

Draw the electron dot structure of the polyatomic chlorate anion, ClO_3^-.

Answers

9.

10. **a.**

b.

Explain

Misconception Alert

Students may mistakenly infer that the atoms that make up polyatomic ions are bonded ionically because polyatomic ions are charged species. However, most polyatomic cations and anions contain covalent and coordinate covalent bonds.

Explore

Teacher Demo

PURPOSE Students observe the formation of nitrogen dioxide and write its resonance structures.

MATERIALS small piece of copper metal, concentrated nitric acid, evaporating dish, fume hood

PROCEDURE Wear safety goggles, gloves, and lab apron. Perform the experiment under an efficient hood.

PROCEDURE Place a small piece of copper in an evaporating dish and cover it with concentrated HNO_3. While students observe the reaction, write the balanced equation for the reaction on the board.

$Cu + 4HNO_3 \rightarrow Cu(NO_3)_2 + 2H_2O + 2NO_2 + \text{energy}$

Tell students that NO_2 is one of the pollutants in automobile exhaust. It gives smog its reddish-brown color and is very reactive and poisonous. Have students try to write the electron dot structure for NO_2. They will be unable to find a way to arrange the 17 electrons around the central nitrogen and the two oxygen atoms so that the octet rule is obeyed. Refer students to the two resonance structures on this page, each with an unpaired electron on the nitrogen atom. Ask them to draw another plausible resonance structure. *(They could draw a structure with the unpaired electron on an oxygen atom.)*

EXPECTED OUTCOMES A reddish-brown gas is produced.

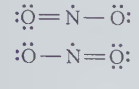
Table 8.2

Some Common Molecular Compounds

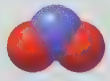
Name	Chemical formula	Structure	Properties and uses
Carbon monoxide	CO	:C≡O:	Colorless, highly toxic gas. It is a major air pollutant present in cigarette smoke and exhaust.
Carbon dioxide	CO_2	:O=C=O:	Colorless unreactive gas. This normal component of the atmosphere is exhaled in the breath of animals and is essential for plant growth.
Hydrogen peroxide	H_2O_2	H–O–O–H	Colorless, unstable liquid when pure. It is used as rocket fuel. A 3% solution is used as a bleach and antiseptic.
Sulfur dioxide	SO_2	:O=S–O:	Oxides of sulfur are produced in the combustion of petroleum products and coal. They are major air pollutants in industrial areas. Oxides of sulfur can lead to respiratory problems.
Sulfur trioxide	SO_3	:O=S(–O:)–O:	
Nitric oxide*	NO	:O=N·	Oxides of nitrogen are major air pollutants produced by the combustion of fossil fuels in automobile engines. They irritate the eyes, throat, and lungs. Nitrogen dioxide, a dark-brown gas, readily converts to colorless dinitrogen tetroxide. Dinitrogen tetroxide is used as a rocket fuel.
Nitrogen dioxide*	NO_2	:O=N–O:	
Dinitrogen tetroxide	N_2O_4	:O(=N–N=O:)–O:	
Nitrous oxide	N_2O	:O←N≡N:	Colorless, sweet-smelling gas. It is used as an anesthetic commonly called laughing gas.
Hydrogen cyanide	HCN	H–C≡N:	Colorless, toxic gas with the smell of almonds.
Hydrogen fluoride	HF	H–F:	Four hydrogen halides, all extremely soluble in water. Hydrogen chloride, a colorless gas with a pungent odor, readily dissolves in water to give a solution called hydrochloric acid.
Hydrogen chloride	HCl	H–Cl:	
Hydrogen bromide	HBr	H–Br:	
Hydrogen iodide	HI	H–I:	

*Does not obey the octet rule

Professional Development Note



Free Radical



Nitrogen dioxide has an odd number of valence electrons, 17, so one electron must be unpaired. Molecules with unpaired electrons are called free radicals and tend to be reactive. Two resonance structures for NO_2 appear on this page. These have the unpaired electron on the nitrogen atom. Two other possible structures place the unpaired electron on oxygen atoms. When free radicals interact, they share their unpaired electrons and create a dimer. Thus, dinitrogen tetroxide, N_2O_4 consists of two nitrogen dioxide molecules joined by a N-N covalent bond. The bond is temperature dependent; at higher temperatures the bond breaks as shown in an equilibrium diagram in Chapter 18.

Exceptions to the Octet Rule

What are some exceptions to the octet rule?

The octet rule provides guidance for drawing electron dot structures. For some molecules or ions, however, it is impossible to draw structures that satisfy the octet rule. **The octet rule cannot be satisfied in molecules whose total number of valence electrons is an odd number. There are also molecules in which an atom has less, or more, than a complete octet of valence electrons.** The nitrogen dioxide (NO_2) molecule, for example, contains a total of seventeen, an odd number, of valence electrons. Each oxygen contributes six electrons and the nitrogen contributes five. Two plausible electron dot structures can be drawn for the NO_2 molecule.

Nitrogen dioxide molecule

An unpaired electron is present in each of these structures, both of which fail to follow the octet rule. It is impossible to draw an electron dot structure for NO_2 that satisfies the octet rule for all atoms. Yet, NO_2 does exist as a stable molecule. In fact, it is produced naturally by lightning strikes of the sort shown in Figure 8.10.

A number of other molecules also have an odd number of electrons. In these molecules, as in NO_2, complete pairing of electrons is not possible. It is not possible to draw an electron dot structure that satisfies the octet rule. Examples of such molecules include chlorine dioxide (ClO_2) and nitric oxide (NO).

Several molecules with an even number of valence electrons, such as some compounds of boron, also fail to follow the octet rule. This outcome may occur because an atom acquires less than an octet of eight electrons. The boron atom in boron trifluoride (BF_3), for example, is deficient by two electrons and, therefore, is an exception to the octet rule. Boron trifluoride readily reacts with ammonia to make the compound $BF_3{\cdot}NH_3$. In doing so, the boron atom accepts the unshared electron pair from ammonia and completes the octet.

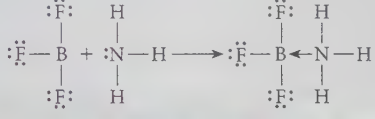


Figure 8.10
Nitrogen Dioxide
Lightning is one means by which nitrogen and oxygen in the atmosphere produce nitrogen dioxide.

Professional Development Note

Paramagnetism

Substances containing unpaired electrons can be identified through a phenomenon called paramagnetism. When molecules with unpaired electrons are placed in a magnetic field, they tend to be drawn into the field. These substances are paramagnetic. In contrast, molecules in which all electrons are paired tend to be pushed from a magnetic field. These substances are diamagnetic.

Paramagnetism differs from ferromagnetism, which is the familiar attraction of metals such as iron, cobalt, and nickel to a magnetic field. The property of paramagnetism is the evidence that shows that the oxygen molecule has unpaired electrons and thus cannot be described exactly by application of the octet rule. However, the oxygen bond does have a double bond character; its bond length and bond energy are similar to those of double bonds in other molecules that conform to the octet rule.

Teacher Demo

PURPOSE Students observe two reactions in which bonds are formed and compare ionic and covalent bond energies.

MATERIALS 10- to 15-cm piece of clean magnesium ribbon, a small piece of charcoal, tongs, Bunsen burner, filters for viewing

SAFETY Wear safety goggles and lab apron. Tie back long hair and loose clothing.

PROCEDURE Using tongs, hold the piece of magnesium in a Bunsen burner flame. CAUTION! Tie back long hair and loose clothing and wear safety goggles. Do not look directly at the flame. Observe through filters. Discuss with students the large amount of heat and light given off in the formation of MgO. Write the balanced equation on the board.

$$2Mg + O_2 \rightarrow 2MgO + \text{energy}$$

Using tongs, place a small piece of charcoal in the Bunsen burner flame and try to ignite it. Write the balanced chemical equation.

$$C + O_2 \rightarrow CO_2 + \text{energy}$$

EXPECTED OUTCOMES Students note that much less energy is given off in forming CO_2 than in forming MgO. **Ask** What kind of bonds are in MgO? *(ionic)* What kind of bonds are in CO_2? *(covalent)* Ionic bond energies are, in general, greater than covalent bond energies.

Explain

Bond Dissociation Energies

SUMMARIZE Direct students' attention to Table 8.3. Explain the units used to measure bond energy and bond length. Have students write a summary statement using any patterns they notice between bonds, bond energy, and bond length.

Extend

Have students draw a graph of actual bond dissociation energies versus number of bonds for carbon-carbon single, double, and triple bonds. Have students write a statement that relates this graph to their conclusions in the lab activity.

Connect to PHYSICS

Have students investigate the relationship between potential energy and bond length. Students should be prepared to state the relationship orally in class as well as demonstrate their findings using two magnets. *(Bond length is the measure at which the potential energy of the combined atoms is at its lowest.)*

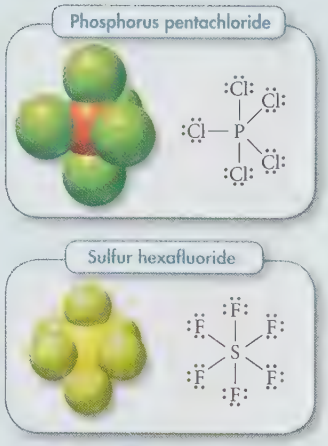

Figure 8.11
Exceptions to the Octet Rule
Phosphorus pentachloride and sulfur hexafluoride, are exceptions to the octet rule.
Interpret Diagrams
How many valence electrons does the sulfur in sulfur hexafluoride (SF_6) have for the structure shown in the figure?

A few atoms, especially phosphorus and sulfur, sometimes expand the octet to ten or twelve electrons. Consider phosphorus trichloride (PCl_3) and phosphorus pentachloride (PCl_5). Both are stable compounds in which all of the chlorine atoms are bonded to a single phosphorus atom. Covalent bonding in PCl_3 follows the octet rule because all the atoms have eight valence electrons. However, as shown in Figure 8.11, the electron dot structure for PCl_5 can be written so that phosphorus has ten valence electrons. The octet is also expanded in sulfur hexafluoride (SF_6). The electron dot structure for SF_6 can be written so that sulfur has twelve valence electrons.

Bond Dissociation Energies

How is the strength of a covalent bond related to its bond dissociation energy?

A large quantity of heat is released when hydrogen atoms combine to form hydrogen molecules. This release of heat suggests that the product is more stable than the reactants. The covalent bond in the hydrogen molecule (H_2) is so strong that it would take 435 kJ of energy to break apart all of the bonds in 1 mole (6.02×10^{23} bonds or about 2 grams) of H_2. (You will study the mole, abbreviated mol, in Chapter 12.) The energy required to break the bond between two covalently bonded atoms is the **bond dissociation energy.** The units for this energy are often given in kJ/mol, which is the energy needed to break one mole of bonds. For example, the bond dissociation energy for the H_2 molecule is 435 kJ/mol.

Table 8.3

Bond Dissociation Energies and Bond Lengths for Covalent Bonds

Bond	Bond dissociation energy (kJ/mol)	Bond length (pm)
H—H	435	74
C—H	393	109
C—O	356	143
C═O	736	121
C≡O	1074	113
C—C	347	154
C═C	657	133
C≡C	908	121
C—N	305	147
Cl—Cl	243	199
N—N	209	140
O—H	464	96
O—O	142	132

UbD Check for Understanding

How is the strength of a covalent bond related to its bond dissociation energy?

Assess students' understanding of covalent bond strength by providing students with a copy of Table 8.3. Have students write down the three strongest covalent bonds in the table and the three weakest. *(Strongest: C triple bond to O; C double bond to C; C double bond to O; Weakest: O single bond to O; N single bond to N; Cl single bond to Cl)*

ADJUST INSTRUCTION If students are struggling to understand this concept, have students create a new the table sorted in order of greatest to least bond energy. As a class, discuss any noticeable patterns.

A large bond dissociation energy corresponds to a strong covalent bond. A typical carbon-carbon single bond has a bond dissociation energy of 347 kJ/mol. Typical carbon-carbon double and triple bonds have bond dissociation energies of 657 kJ/mol and 908 kJ/mol, respectively. Strong carbon-carbon bonds help explain the stability of carbon compounds. Compounds with only C—C and C—H single covalent bonds, such as methane, tend to be quite unreactive. They are unreactive partly because the dissociation energy for each of these bonds is high. Bond dissociation energies of some common bonds are shown in Table 8.3.

Q: *What is the difference between the oxygen you breathe and the oxygen in ozone in the atmosphere?*

Resonance

How are resonance structures used?

Ozone in the upper atmosphere blocks harmful ultraviolet radiation from the sun. At lower elevations, as shown in Figure 8.12, it contributes to smog. The ozone molecule has two possible electron dot structures. Notice that the structure on the left can be converted to the one on the right by shifting electron pairs without changing the positions of the oxygen atoms.

As drawn, these electron dot structures suggest that the bonding in ozone consists of one single coordinate covalent bond and one double covalent bond. Because earlier chemists imagined that the electron pairs rapidly flip back and forth, or resonate, between the different electron dot structures, they used double-headed arrows to indicate that two or more structures are in resonance.

Double covalent bonds are usually shorter than single covalent bonds, so it was believed that the bond lengths in ozone were unequal. Experimental measurements show, however, that this is not the case. The two bonds in ozone are the same length. This result can be explained if you assume that the actual bonding in the ozone molecule is the average of the two electron dot structures. The electron pairs do not actually resonate back and forth. The actual bonding is a hybrid, or mixture, of the extremes represented by the resonance forms.

The two electron dot structures for ozone are examples of what are still referred to as resonance structures. **Resonance structures** are structures that occur when it is possible to draw two or more valid electron dot structures that have the same number of electron pairs for a molecule or ion. **Chemists use resonance structures to envision the bonding in molecules that cannot be adequately described by a single structural formula.** Although no back-and-forth changes occur, double-headed arrows are used to connect resonance structures.

Figure 8.12 Ozone Smog
Although ozone high above the ground forms a protective layer that absorbs ultraviolet radiation from the sun, at lower elevations ozone is a pollutant that contributes to smog. The smog shown here in Los Angeles, California, makes it difficult to see the city skyline.

Focus on ELL

4 LANGUAGE PRODUCTION Have students work in groups of four to complete the lab. Make sure each group has ELLs of varied language proficiencies, so that more proficient students can help less proficient ones. Have students work according to their proficiency level.

BEGINNING: LOW/HIGH Model this lab and use student volunteers to help with each step. For example, ask one student to take the measurements, another student to record the measurements, etc.

INTERMEDIATE: LOW/HIGH Add a picture to each step of the lab that will demonstrate the procedure. Provide a chart for recording data and labeled graph paper for the graph.

ADVANCED: LOW/HIGH Ask students to compare and contrast in writing the stretching of rubber bands and the dissociation energy of covalent bonds.

Explain

Resonance

START A CONVERSATION Although the electron dot structures of O_2 on page 229 show that all electrons are paired, experimental evidence reveals that two electrons are unpaired. **Ask** Would you consider oxygen a reactive gas? *(yes)* What could account for oxygen's reactivity? **Ask** *(Unpaired electrons are reactive.)* After a brief discussion of the other exceptions to the octet rule that are presented in this section, remind students that many bonds do follow the octet rule.

SUMMARIZE Have students complete the bulleted list summarizing the types of situations that may have exceptions to the octet rule.

- molecules with an ___ number of electrons *(odd)*
- molecules where one atom has more or less than an ____ *(octet)*

Evaluate

Informal Assessment

Challenge students to write electron dot structures for SBr_2 and C_3H_8. Have students work in pairs to determine whether or not their structures are correct, and if not, how to correct their errors. Then, have students explain coordinate covalent bonding in their own words. *(A coordinate covalent bond is formed when one atom contributes both bonding electrons.)* **Ask** When do resonance structures occur? *(Resonance structures occur when two or more valid electron dot structures can be written for a molecule.)* Then have students complete the 8.2 Lesson Check.

Reteach

As a class, create a concept map interlinking each concept covered in the lesson. Have students use their notes as well as the textbook to add as much detail as possible. Creating a visual relationship of the concepts may help solidify students' understanding.

Answers

INTERPRET DIAGRAMS 12 valence electrons

LESSON 8.2

Explore

QuickLab

OBJECTIVE After completing this activity, students will understand that the dissociation energy of a covalent bond increases in order from single bond to double bond to triple bond.

SKILLS FOCUS Solving, interpreting

PREP TIME 10 minutes

CLASS TIME 30 minutes

MATERIALS Obtain the necessary materials in advance. You may wish to ask students to help with this task by bringing cans of food, coat hangers, and plastic grocery bags to class.

TEACHING TIP Use tape to secure the hanger in place if necessary. Have groups of students record the data and then create a graph as a class, using an overhead projector.

EXPECTED OUTCOMES As the mass of the load increases, the stretch of the rubber band or bands increases. For a given mass, a single rubber band stretches farther than a double, and a double rubber band stretches farther than a triple.

ANALYZE AND CONCLUDE

1. Triple covalent bonds are stronger than double covalent bonds, which are stronger than single covalent bonds.
2. The change in bond dissociation energies in going from a carbon-carbon single bond to a carbon-carbon double bond to a carbon-carbon triple bond is nearly constant. The change in length of one, two, and three rubber bands, as given by the slopes of the lines, is not constant. It is large going from one to two rubber bands and small going from two to three rubber bands.

QuickLab

Strengths of Covalent Bonds

Purpose To compare and contrast the stretching of rubber bands and the dissociation energy of covalent bonds

Materials

- 1 170-g (6-oz) can of food
- 2 454-g (16-oz) cans of food
- 3 No. 25 rubber bands
- metric ruler
- coat hanger
- plastic grocery bag
- paper clip
- graph paper
- motion detector (optional)

Procedure

1. Bend the coat hanger to fit over the top of a door. The hook should hang down on one side of the door. Measure the length of the rubber bands (in cm). Hang a rubber band on the hook created by the coat hanger.
2. Place the 170-g can in the plastic bag. Use the paper clip to fasten the bag to the end of the rubber band. Lower the bag gently until it is suspended from the end of the rubber band. Measure and record the length of the stretched rubber band. Using different combinations of food cans, repeat this process three times with the following masses: 454 g, 624 g, and 908 g.
3. Repeat Step 2, first using two rubber bands to connect the hanger and the paper clip, and then using three.
4. Graph the length difference: (stretched rubber band) – (unstretched rubber band) on the *y*-axis versus mass (kg) on the *x*-axis for one, two, and three rubber bands. Draw the straight line that you estimate best fits the points for each set of data. (Your graph should have three separate lines.) The *x*-axis and *y*-axis intercepts of the lines should pass through zero, and the lines should extend past 1 kg on the *x*-axis. Determine the slope of each line in cm/kg.

Analyze and Conclude

1. **Analyze Experimental Results** Assuming the rubber bands are models for covalent bonds, what can you conclude about the relative strengths of single, double, and triple bonds?
2. **Evaluate** How does the behavior of the rubber bands differ from that of covalent bonds?

8.2 LessonCheck

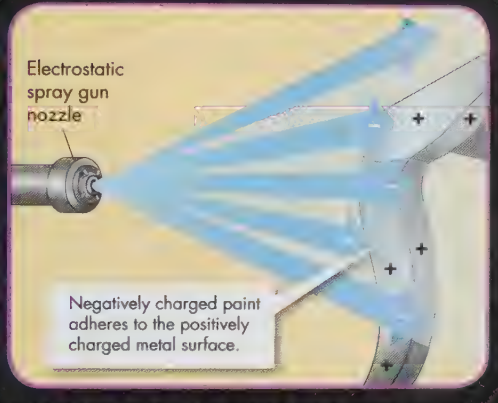
11. **Identify** What electron configurations do atoms usually achieve by sharing electrons to form covalent bonds?
12. **Compare** How is a coordinate covalent bond different from other covalent bonds?
13. **Explain** How is the strength of a covalent bond related to its bond dissociation energy?
14. **List** List three ways in which the octet rule can sometimes fail to be obeyed.
15. **Identify** Draw the electron dot resonance structures for ozone and explain how they describe its bonding.
16. **Explain** How is an electron dot structure used to represent a covalent bond?
17. **Infer** When are two atoms likely to form a double bond between them? A triple bond?
18. **Identify** What kinds of information does a structural formula reveal about the compound it represents?
19. **Compare** Use the bond dissociation energies of H_2 and of a typical carbon–carbon bond to decide which bond is stronger. Explain your reasoning.
20. **Use Models** Draw electron dot structures for the following molecules, which have only single covalent bonds:
    a. H_2S b. PH_3 c. ClF

Lesson Check Answers

11. the configurations of noble gases
12. The shared electron pair comes from one of the bonding atoms. In other covalent bonds, each bonding atom provides an electron.
13. A large bond dissociation energy corresponds to a strong covalent bond.
14. The octet rule cannot be satisfied in molecules whose total number of valence electrons is an odd number. There are also molecules in which an atom has fewer, or more, than a complete octet of valence electrons.
15. $:\ddot{O}:\ddot{O}::\ddot{O}: \longleftrightarrow :\ddot{O}::\ddot{O}:\ddot{O}:$ The actual bonding of oxygen atoms in ozone is a hybrid, or mixture, of the extremes represented by the resonance forms.
16. Two dots represent each covalent bond.
17. when they can attain a noble gas structure by sharing two pairs or three pairs of electrons
18. the arrangement of atoms in a molecule
19. The H-H bond is stronger because it has a greater dissociation energy.
20. a. $H:\ddot{S}:H$

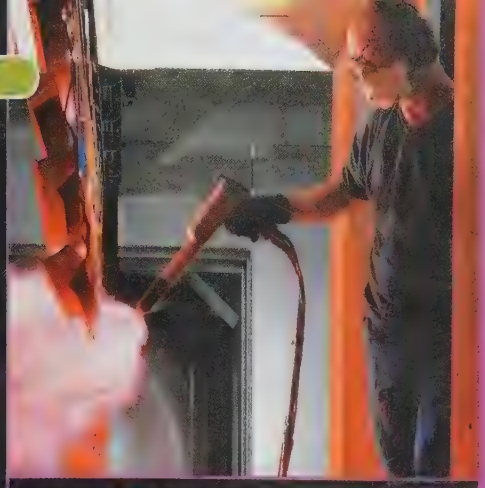
    b. $H:\ddot{P}:H$ (H)

    c. $:\ddot{Cl}:\ddot{F}:$



Powder Coating

Have you ever admired a new car with its glossy, smooth paint? Car manufacturers use a special process to apply paint to a car. This process is called powder coating or electrostatic spray painting.



In powder coating, a custom-designed spray nozzle wired up to an electric power supply imparts a negative charge to the paint droplets as they exit the spray gun. The negatively charged droplets are attracted to the grounded, positively-charged, metal surface. Painting with attractive forces is very efficient, because almost all the paint is applied to the car body and very little is wasted.

Powder coating isn't just for cars. The process has many different applications, including the painting of motorcycles, outdoor furniture, exercise equipment, office furniture, and metal fencing.

An eye-catching paint finish isn't the only benefit of powder coating, however. This process is also environmentally friendly. Since the paint is actually attracted to its intended surface, the amount of wasted paint is much lower compared to traditional spray painting. Also, the amount of toxic volatile organic compounds (VOCs) released is minimal, if there are any at all.

ATTRACTIVE PAINT The paint almost wraps around the metal, sticking to any available charged surface.

APPLYING THE POWDER This worker is using an electrostatic spray gun to apply powder to the metal. Any powder that does not stick to the part can be collected and reused. Once the powder is applied, the part is baked in an oven to cure the paint.

GLOSSY FINISH Powder coating can produce a smooth, glossy paint finish.

Take It Further

1. Analyze Benefits Powder coating is being used for more and more applications, partly because of its many benefits. Research other advantages of powder coating that are not mentioned here.

2. Infer Powder coating results in a smooth surface, usually without drips and runs. Given what you have learned about attractive forces, why do you think drips and runs are avoided during powder coating?

21st Century Learning To be successful in the 21st century, students need skills and learning experiences that extend beyond subject matter mastery. The following project helps students build the following 21st Century Skills: *Financial, Economic, Business, and Entrepreneurial Literacy*; *Creativity and Innovation*; *Communication and Collaboration*; *Information, Media, and Technology Literacy*; *Initiative and Self-Direction*; *and Productivity and Accountability*.

CLEANER COATINGS Tell students that due to the social and political viewpoint towards ecological awareness, controlling emissions and waste is an ever increasing concern in all areas of manufacturing. Pose the following challenge to students: *As members of a powder coating company's sales department, it is your job to convince a major plastics manufacturer to replace their liquid coating process with powder coating.* Create "marketing teams" of 4–6 people to develop a multimedia marketing campaign designed to convince the plastics manufacturer of the benefits of switching to powder coating. It should include a comparison of current powder coating and liquid coating processes from the standpoint of environmental impact and worker safety. Record the campaign on DVD for submission.

CHEMISTRY & YOU The automotive industry is an example of an industry that is strongly swayed by consumer concerns.

Pose the following question to students: *What are some likely consumer concerns that have had or could potentially have an effect on the types of technological advancements in the automotive industry, and how did the automotive industry respond to those concerns?*

You may need to guide students in the following ways:

- Safety developments include shoulder restraints, front and side curtain airbags, reinforced frames, anti-lock brakes, enhanced traction systems, in-trunk release latches, xenon headlamps, and LED tail lamps.
- Fuel efficiency developments include computer controlled engines, fuel injection, automated manual and continually variable transmissions, reductions in gross vehicular weight
- Emissions regulation developments include catalytic converters, low carbon fuels (ethanol and CNG), hybrid engines, exhaust gas recirculation, and evaporative emission systems.

Explain

START A CONVERSATION Direct students to read about the powder coating process highlighted in this feature and to examine the photographs. **Ask** What is the basic underlying chemistry-related principle applied in the powder coating process? *(Opposite charges are inherently attracted to each other.)* **Ask** Do you know of other types of coating processes used in other industries? *(Sample answers: electroplating, galvanizing, Parkerizing, bluing, painting, etc.)* **Ask** What do you think the benefits are for using powder coating over one of these other processes? *(Sample answers: durability of the surface, even coating, longevity, avoiding corrosion issues due to weather, etc.)*

Answers

1. Answers may vary, but possible benefits include the ability to recover unused or over-sprayed powder, and the production of a strong, scratch-resistant paint finish.
2. Since the paint is attracted to the metal, excess paint that might normally form drips is instead attracted to metal that is not yet covered in paint.

LESSON 8.3

Key Objectives

- **8.3.1 DESCRIBE** the relationship between atomic and molecular orbitals.
- **8.3.2 DESCRIBE** how VSEPR theory helps predict the shapes of molecules.
- **8.3.3 IDENTIFY** the ways in which orbital hybridization is useful in describing molecules.

Engage

CHEMISTRY & YOU Have students study the photograph and read the opening text. Explain that topographic maps are usually drawn as a series of lines tracing the elevations of a terrain. The more closely spaced the lines are, the steeper is the terrain. Similarly, scientists can use X-ray diffraction data to map the electron density at any position in a crystal of a particular molecule. Where the lines are closest in the map, the electron density of the molecule is greatest.

Build Background

Have students recall what they know about hybrid organisms or cars. **Ask** What does the term *hybrid* mean to you? *(Sample answer: A hybrid has a combination of characteristics of two or more different organisms or objects, but is different from any of the originals.)* Tell students to keep this in mind as they proceed with the lesson.

IN ACADEMIC STANDARDS for SCIENCE

C.3.1 Describe, compare, and contrast the characteristics of the interactions between atoms in ionic and covalent compounds.

C.3.2 Compare and contrast how ionic and covalent compounds form.

C.3.3 Compare and contrast ionic, covalent network, metallic and polar and non-polar molecular crystals with respect to constituent particles, strength of bonds, melting and boiling points, and conductivity; provide examples of each type.

C.3.4 Draw structural formulas for and name simple molecules.

8.3 Bonding Theories

IN C.3.1 Interactions between atoms in ionic and covalent compounds; C.3.2 Formation of ionic and covalent compounds; C.3.3 Chemical bonds and intermolecular attractions; C.3.4 Structural formulas

CHEMISTRY & YOU

Q: *How can you predict where an electron is most likely to be found in a molecule?* If you ever go hiking in a hilly area, you might see a topographic map like the one shown here. The lines on a topographic map show you where elevations change. In this lesson, you will learn how to interpret electron "maps" that show where you are most likely to find electrons.

Key Questions

- *How are atomic and molecular orbitals related?*
- *What do scientists use the VSEPR theory for?*
- *In what ways is orbital hybridization useful in describing molecules?*

Vocabulary

- molecular orbital
- bonding orbital
- sigma bond
- pi bond
- tetrahedral angle
- VSEPR theory
- hybridization

Molecular Orbitals

How are atomic and molecular orbitals related?

The model you have been using for covalent bonding assumes the orbitals are those of the individual atoms. There is a quantum mechanical model of bonding, however, that describes the electrons in molecules using orbitals that exist only for groupings of atoms. When two atoms combine, this model assumes that their atomic orbitals overlap to produce **molecular orbitals,** or orbitals that apply to the entire molecule.

In some ways, atomic orbitals and molecular orbitals are similar. **Just as an atomic orbital belongs to a particular atom, a molecular orbital belongs to a molecule as a whole.** Each atomic orbital is filled if it contains two electrons. Similarly, two electrons are required to fill a molecular orbital. A molecular orbital that can be occupied by two electrons of a covalent bond is called a **bonding orbital.**

Sigma Bonds When two atomic orbitals combine to form a molecular orbital that is symmetrical around the axis connecting two atomic nuclei, a **sigma bond** is formed, as illustrated in Figure 8.13. The symbol for this bond is the Greek letter sigma (σ).

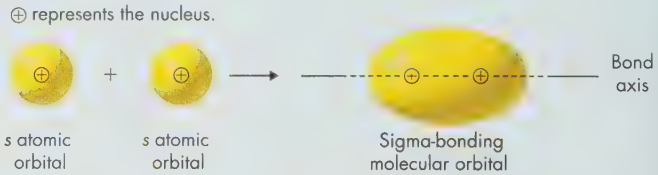

Figure 8.13 *s* Orbital Sigma Bonds
Two *s* atomic orbitals can combine to form a molecular orbital, as in the case of hydrogen (H_2). In a bonding molecular orbital, the electron density between the nuclei is high.

Focus on ELL

1 CONTENT AND LANGUAGE Write the words *axis*, *symmetrical*, and *repulsion* on the board. Define each term and have students add these words to their vocabulary notebooks. Have students identify other terms in the lesson with which they need assistance. Define these terms as needed.

2 FRONTLOAD THE LESSON Blow up and tie off nine balloons. Tie the balloons together with string to form three clusters: two balloons, three balloons, and four balloons. Explain that each balloon represents an electron pair around a central atom. Read aloud the Essential Question, *How do electrons affect the shape of molecule?* Have each group predict the answer based on what they have observed.

3 COMPREHENSIBLE INPUT Show students computerized or ball-and-stick versions of the molecules in Figure 8.18. Rotate the models so students can fully appreciate that the models are three-dimensional.

⊕ represents the nucleus.

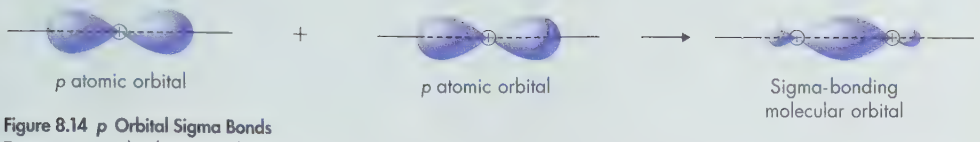

Figure 8.14 *p* Orbital Sigma Bonds
Two *p* atomic orbitals can combine to form a sigma-bonding molecular orbital, as in the case of fluorine (F_2). Notice that the sigma bond is symmetrical around the bond axis connecting the nuclei.

In general, covalent bonding results from an imbalance between the attractions and repulsions of the nuclei and electrons involved. Because their charges have opposite signs, the nuclei and electrons attract each other. Conversely, nuclei repel other nuclei and electrons repel other electrons because their charges have the same sign. In a hydrogen molecule, the nuclei repel each other, as do the electrons. In a bonding molecular orbital of hydrogen, however, the attractions between the hydrogen nuclei and the electrons are stronger than the repulsions. The balance of all the interactions between the hydrogen atoms is thus tipped in favor of holding the atoms together. The result is a stable diatomic molecule of H_2.

Atomic *p* orbitals can also overlap to form molecular orbitals. A fluorine atom, for example, has a half-filled 2*p* orbital. When two fluorine atoms combine, as shown in Figure 8.14, the *p* orbitals overlap to produce a bonding molecular orbital. There is a high probability of finding a pair of electrons between the positively charged nuclei of the two fluorines. The fluorine nuclei are attracted to this region of high electron density. This attraction holds the atoms together in the fluorine molecule (F_2). The overlap of the 2*p* orbitals produces a bonding molecular orbital that is symmetrical when viewed around the F—F bond axis connecting the nuclei. Therefore, the F—F bond is a sigma bond.

CHEMISTRY & YOU

Q: *Models and drawings are often used to help you visualize where something can be found. How can a drawing show you where an electron is most likely to be found?*

Pi Bonds In the sigma bond of the fluorine molecule, the *p* atomic orbitals overlap end to end. In some molecules, however, orbitals can overlap side by side. As shown in Figure 8.15, the side-by-side overlap of atomic *p* orbitals produces what are called pi molecular orbitals. When a pi molecular orbital is filled with two electrons, a pi bond results. In a **pi bond** (symbolized by the Greek letter π), the bonding electrons are most likely to be found in sausage-shaped regions above and below the bond axis of the bonded atoms. Atomic orbitals in pi bonding overlap less than in sigma bonding. Therefore, pi bonds tend to be weaker than sigma bonds.

⊕ represents the nucleus.

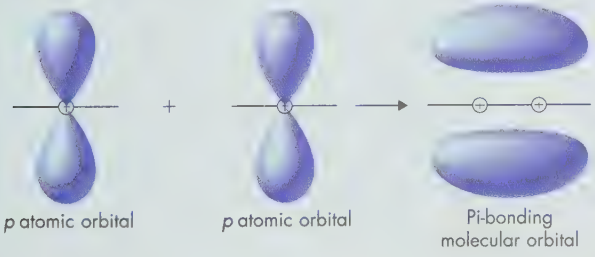

Figure 8.15
***p* Orbital Pi Bonds**
The side-by-side overlap of two *p* atomic orbitals produces a pi-bonding molecular orbital. Together, the two sausage-shaped regions in which the bonding electron pair is most likely to be found constitute one pi-bonding molecular orbital.

UbD Check for Understanding

BIGIDEA BONDING AND INTERACTIONS Have students write one-minute summaries comparing and contrasting sigma and pi bonds.

ADJUST INSTRUCTION If students are having difficulty with their summaries, create and complete a compare and contrast chart on this concept.

Foundations for Reading

BUILD VOCABULARY Explain that the prefix *tetra-* is a Greek word meaning "four," and *hedra-* is a Greek word meaning "face." Explain that a tetrahedron is a four-faced 3-dimensional figure. Prior to introducing the VSEPR theory, remind students that *bi-* means "two," *tri-* means "three," and *octa-* means "eight." Help students to identify the meaning of the acronym VSEPR.

READING STRATEGY As students read about atomic and molecular orbitals, encourage them to make a table in which to list similarities and differences. As you approach the end of the lesson, tell students to expand their table to include hybrid orbitals.

Explain

Molecular Orbitals

USE VISUALS Direct students to examine Figure 8.13. Have them note the positions of the two nuclei in the two hydrogen atomic orbitals. **Ask** Where is the electron most likely to be in the hydrogen atomic orbital? *(In the sphere, close to the nucleus.)* **Ask** Where are the two shared electrons likely to be in the H_2 molecular orbital? *(In the region between the two nuclei.)*

CHEMISTRY & YOU The shape of drawing represents where electrons are most likely to be found.

APPLY CONCEPTS Tell students to visualize the formation of the covalent bond in H_2 as two separated hydrogen atoms move closer together. Explain that as the distance between the atoms decreases, each nucleus is attracted by both electrons, and the potential energy of the system decreases. Explain that repulsive forces also come into play as the nuclei and the electrons of both atoms begin to repel each other. An interatomic distance is reached at which the potential energy is at a minimum. If the distance decreases beyond this point, the potential energy increases because of increased repulsion. Explain that this results in a chemical bond with a bond length equal to the interatomic distance at which the potential energy is a minimum.

USE VISUALS Have students compare Figures 8.14 and 8.15. **Ask** What is different about the ways that the two *p* orbitals overlap in the two illustrations? *(In Figure 8.14, the* p *orbitals overlap end-to-end, forming an orbital that is symmetrical around the axis joining the nuclei. In Figure 8.15, the* p *orbitals overlap side-by-side and form two areas of electron density, one above and another below the axis joining the nuclei.)* Have students identify the two types of bonds. *(Figure 8.14, sigma bond; Figure 8.15, pi bond)*

Explain

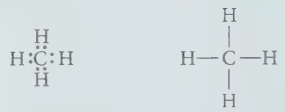
VSEPR Theory

START A CONVERSATION Display the electron configuration for carbon: $1s^2 2s^1 2p^3$. **Ask** How many valence electrons does carbon have? *(4)* **Ask** How many bonds does carbon form? *(4)* **Ask** What do you know about the three *p* orbitals? *(They are dumbbell-shaped orbitals containing two lobes; the three orbitals are perpendicular to each other, oriented on the* x-, y-, *and* z-*axes.)* Convey to students that if carbon forms three of its four bonds using *p* orbitals, then the resulting molecules it forms must be three-dimensional.

Explore

Class Activity

PURPOSE Students achieve an understanding of simple molecular shapes and relate actual three-dimensional geometry to two-dimensional illustrations.



MATERIALS ball-and-stick molecular model kits or foam balls and toothpicks

PROCEDURE Have students make the tetrahedral model of methane. Have them examine the model and compare it with the illustrations in Figure 8.16. Ask them to draw the model and label it *tetrahedral.* Have students remove one ball, leaving the stick in place. The stick can represent an unshared pair of electrons. This is a model for the ammonia molecule. Again, have students compare their models with Figure 8.16 and make their own illustration, labeling it *pyramidal.* Have students remove a second ball. Now the model simulates the water molecule with two sticks (pairs of unshared electrons). Have students compare their models with Figure 8.17 and make their own illustration labeled *bent triatomic.*

VSEPR Theory

What do scientists use the VSEPR theory for?

A photograph or sketch may fail to do justice to your appearance. Similarly, electron dot structures fail to reflect the three-dimensional shapes of the molecules illustrated in Figure 8.16. The electron dot structure and structural formula of methane (CH_4), for example, show the molecule as if it were flat and merely two-dimensional.

Methane (electron dot structure) — Methane (structural formula)

READING SUPPORT

BUILD VOCABULARY: *Word Origins* *Tetrahedral* comes from the Greek *tetra-*, meaning "four," and *hedra,* meaning "face." ***How do these word origins help you understand the shapes of molecules?***

In reality, methane molecules are three-dimensional. As Figure 8.16a shows, the hydrogens in a methane molecule are at the four corners of a geometric solid called a regular tetrahedron. In this arrangement, all of the H—C—H angles are 109.5°, the **tetrahedral angle.**

In order to explain the three-dimensional shape of molecules, scientists use valence-shell electron-pair repulsion theory (VSEPR theory). VSEPR theory states that the repulsion between electron pairs causes molecular shapes to adjust so that the valence-electron pairs stay as far apart as possible. The methane molecule has four bonding electron pairs and no unshared pairs. The bonding pairs are farthest apart when the angle between the central carbon and its attached hydrogens is 109.5°. This measurement is the H—C—H bond angle found experimentally.

Unshared pairs of electrons are also important in predicting the shapes of molecules. The nitrogen in ammonia (NH_3) is surrounded by four pairs of valence electrons, so you might predict the tetrahedral angle of 109.5° for the H—N—H bond angle. However, one of the valence-electron pairs shown in Figure 8.16b is an unshared pair. No bonding atom is vying for these unshared electrons. Thus, they are held closer to the nitrogen than are the bonding pairs. The unshared pair strongly repels the bonding pairs, pushing them together. The measured H—N—H bond angle is only 107°.

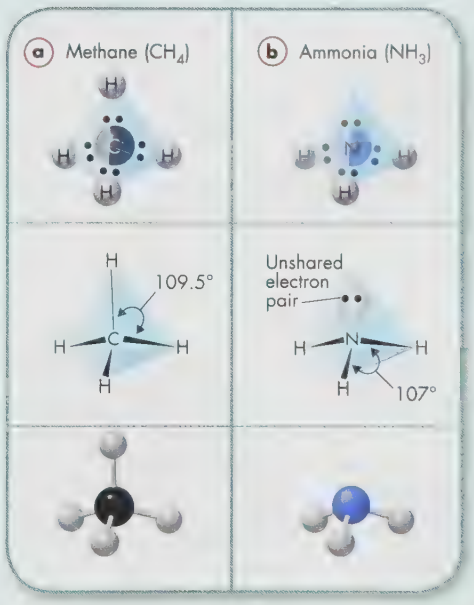


Figure 8.16 Three-Dimensional Molecules **a.** Methane is a tetrahedral molecule. The hydrogens in methane are at the four corners of a regular tetrahedron, and the bond angles are all 109.5°. **b.** An ammonia molecule is pyramidal. The unshared pair of electrons repels the bonding pairs.
Use Models ***How do the resulting H—N—H bond angles compare to the tetrahedral angle?***

Differentiated Instruction

LPR LESS PROFICIENT READERS Give students as many opportunities as possible to see three-dimensional models of molecules. When you write formulas on the chalkboard, try to have a three-dimensional model to hold up or circulate around the class. This will help students interpret the two-dimensional drawings of these three-dimensional figures.

L1 SPECIAL NEEDS Offer students mediums such as modeling clay, colored marshmallows, colored gumdrops, licorice, and straws to mimic the models shown throughout the lesson. Display the models in the classroom and make a point to use these models, giving credit to its creator, when explaining a concept.

L3 ADVANCED STUDENTS Explain that molecular orbital theory is a third way of treating chemical bonding in addition to the valence bond approach and VESPR theory. Explain that each approach to bonding contributes different yet important ideas. Molecular orbital theory is a quantum mechanical approach involving not just localized bonds but bonds that bind entire molecules. Encourage students to access a college text and learn more about this theory and how it explains the paradox of bonding in the oxygen molecule.

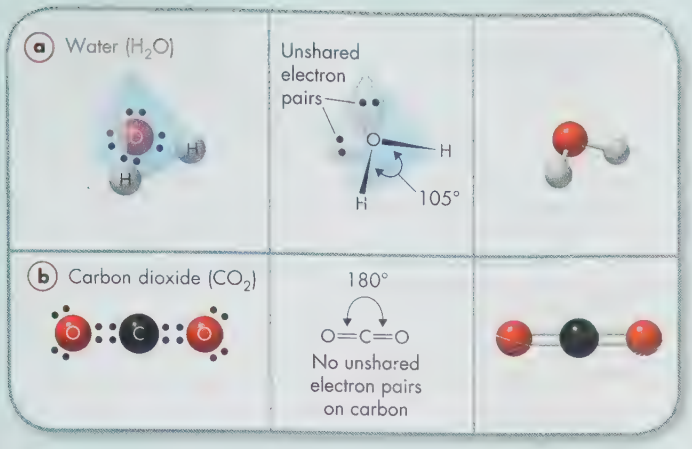

Figure 8.17
Planar and Linear Molecules
This comparison of water and carbon dioxide illustrates how unshared pairs of electrons can affect the shape of a molecule made of three atoms. **a.** The water molecule is bent because the two unshared pairs of electrons on oxygen repel the bonding electrons. **b.** In contrast, the carbon dioxide molecule is linear. The carbon atom has no unshared electron pairs.

In a water molecule, oxygen forms single covalent bonds with two hydrogen atoms. The two bonding pairs and the two unshared pairs of electrons form a tetrahedral arrangement around the central oxygen. Thus, the water molecule is planar (flat) but bent. With two unshared pairs repelling the bonding pairs, the H—O—H bond angle is compressed in comparison with the H—C—H bond angle in methane. The experimentally measured bond angle in water is about 105°, as shown in Figure 8.17a.

In contrast, the carbon in a carbon dioxide molecule has no unshared electron pairs. As illustrated in Figure 8.17b, the double bonds joining the oxygens to the carbon are farthest apart when the O=C=O bond angle is 180°. Thus, CO_2 is a linear molecule. Nine of the possible molecular shapes are shown in Figure 8.18.

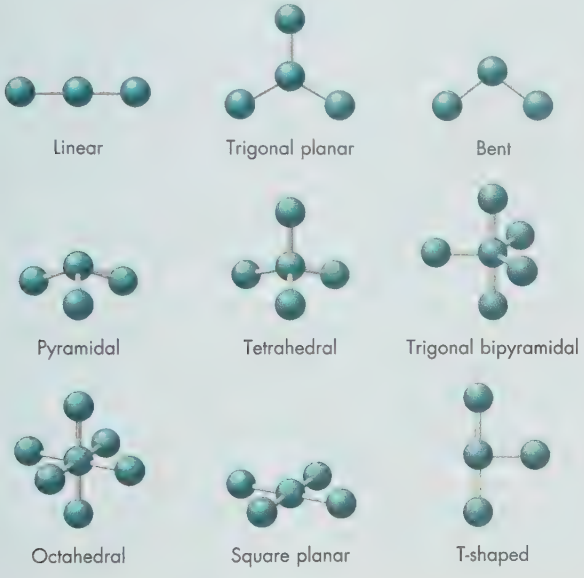

Figure 8.18
Molecular Shapes
Shown here are common molecular shapes.
Infer *What is the shape of an ammonium ion?*

UbD Check for Understanding

The Essential Question **How do electrons affect the shape of a molecule?**

Direct students to Figure 8.18. Have students choose three molecular shapes, then identify and draw a compound that corresponds to each structure. Make sure that students include at least one compound that contains an unshared pair of electrons.

ADJUST INSTRUCTION If students are having difficulty with this concept, review Figures 8.16 and 8.17, making sure to point out the influence exerted over molecular shape by the unshared pairs of electrons associated with nitrogen and oxygen in the illustrated compounds.

Explain

START A CONVERSATION Help students understand that VSEPR theory is a model or method used to *predict* molecular shapes based on electron repulsion. In predicting molecular shapes, they may find it helpful to start with an electron dot structure. The electron dot structure shows both the bonding and nonbonding pairs of electrons around the central atom. Point out that when using VSEPR theory to predict molecular shape, double and triple bonds are viewed as single bonds. Each group of electrons in the electron dot structure must be accommodated around the central atom. Because electrons repel each other, they will stay as far apart as possible. When four pairs must be accommodated, the pairs have maximum space when they are arranged tetrahedrally with an angle of 109.5° between them. When three pairs or groups must be accommodated, a trigonal planar arrangement provides the most space with 120° separating them. Finally, when only two groups are present, they will adopt a linear arrangement in which they are separated by 180°. Have students predict the shapes of H_2S and BF_3. *(bent and trigonal planar, respectively)*

Answers

FIGURE 8.16 They are smaller.
FIGURE 8.18 tetrahedral

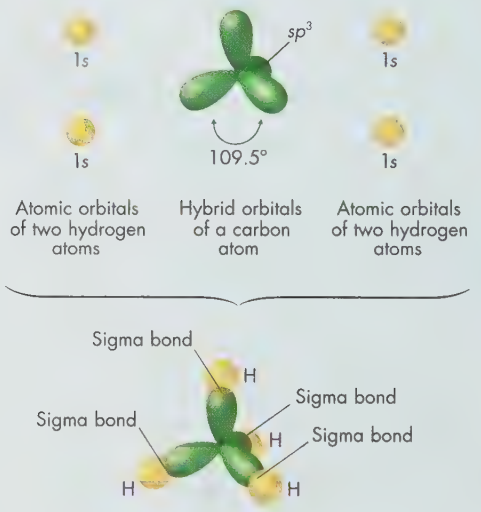
Explain

Hybrid Orbitals

USE VISUALS Direct students to refer to their periodic table. Verify that students are aware that third row nonmetals such as phosphorus and sulfur, in Groups 15 and 16, respectively, can form more bonds than the number predicted by the octet rule. For example, show students that phosphorus can form PCl_5 as well as PCl_3, and sulfur can form SF_6 as well as SF_2. Point out that second period elements in the same groups, such as nitrogen and oxygen, do not form compounds that violate the octet rule. The difference lies in the fact that third period elements can promote electrons to empty 3*d* orbitals. Second period elements have no 2*d* orbitals.

Explain that bonding in phosphorus and sulfur in compounds such as PCl_5 and SF_6 involves hybrid orbitals. For phosphorus, one *s*, three *p*, and one *d* orbitals combine to form five dsp^3 hybrid orbitals. The geometry of a set of five dsp^3 orbitals is trigonal bipyramidal. For sulfur, one *s*, three *p*, and two *d* orbitals combine to form six d^2sp^3 hybrid orbitals. The geometry of six d^2sp^3 orbitals is octahedral.

Hybrid Orbitals



In what ways is orbital hybridization useful in describing molecules?

The VSEPR theory works well when accounting for molecular shapes, but it does not help much in describing the types of bonds formed. **Orbital hybridization provides information about both molecular bonding and molecular shape.** In **hybridization,** several atomic orbitals mix to form the same total number of equivalent hybrid orbitals.

Hybridization Involving Single Bonds Recall that the carbon atom's outer electron configuration is $2s^22p^2$, but one of the 2*s* electrons is promoted to a 2*p* orbital to give one 2*s* electron and three 2*p* electrons, allowing it to bond to four hydrogen atoms in methane. You might suspect that one bond would be different from the other three. In fact, all the bonds are identical. This fact is explained by orbital hybridization.

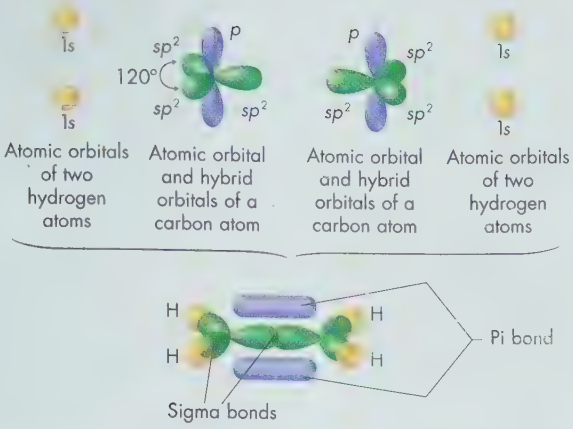
The one 2*s* orbital and three 2*p* orbitals of a carbon atom mix to form four sp^3 hybrid orbitals. These are at the tetrahedral angle of 109.5°. As you can see in Figure 8.19, the four sp^3 orbitals of carbon overlap with the 1*s* orbitals of the four hydrogen atoms. The sp^3 orbitals extend farther into space than either *s* or *p* orbitals, allowing a great deal of overlap with the hydrogen 1*s* orbitals. The eight available valence electrons fill the molecular orbitals to form four C—H sigma bonds. The extent of overlap results in unusually strong covalent bonds.

Figure 8.19 Methane Molecule
In methane, each of the four sp^3 hybrid orbitals of carbon overlaps with a 1*s* orbital of hydrogen.

Professional Development Note

Towering 20th Century Chemist

An esteemed chemist and dedicated humanitarian, Linus Pauling (1916–1994) is the only person to have won two Nobel prizes that were unshared. In 1954 he won the prize for chemistry; in 1962 he won the prize for peace. The peace prize recognized his efforts to bring nuclear weapons under international control and halt nuclear testing. Much of his scientific work involved the structure of simple and complex molecules. His book *The Nature of the Chemical Bond and the Structure of Molecules and Crystals* is one of the most important texts of the century. Pauling introduced the idea of hybrid orbitals to explain why the four bonds around a carbon atom are equivalent. He invented the concept of electronegativity and proposed that most covalent bonds have some ionic character. He also taught that the structures of some compounds must be described by two or more resonance hybrids.



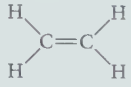


Figure 8.20 Ethene Molecule
In an ethene molecule, two sp^2 hybrid orbitals from each carbon overlap with a 1s orbital of hydrogen to form a sigma bond. The other sp^2 orbitals overlap to form a carbon-carbon sigma bond. The *p* atomic orbitals overlap to form a pi bond.
Infer ***What region of space does the pi bond occupy relative to the carbon atoms?***

Hybridization Involving Double Bonds Hybridization is also useful in describing double covalent bonds. Ethene is a relatively simple molecule that has one carbon–carbon double bond and four carbon–hydrogen single bonds.

Ethene

Experimental evidence indicates that the H—C—H bond angles in ethene are about 120°. In ethene, sp^2 hybrid orbitals form from the combination of one 2*s* and two 2*p* atomic orbitals of carbon. As you can see in Figure 8.20, each hybrid orbital is separated from the other two by 120°. Two sp^2 hybrid orbitals of each carbon form sigma-bonding molecular orbitals with the four available hydrogen 1*s* orbitals. The third sp^2 orbitals of each of the two carbons overlap to form a carbon-carbon sigma-bonding orbital. The nonhybridized 2*p* carbon orbitals overlap side by side to form a pi-bonding orbital. A total of twelve electrons fill six bonding molecular orbitals. Thus, five sigma bonds and one pi bond hold the ethene molecule together. Although they are drawn alike in structural formulas, pi bonds are weaker than sigma bonds. In chemical reactions that involve breaking one bond of a carbon-carbon double bond, the pi bond is more likely to break than the sigma bond.

Hybridization Involving Triple Bonds A third type of covalent bond is a triple bond, which is found in ethyne (C_2H_2), also called acetylene.

H—C≡C—H

As with other molecules, the hybrid orbital description of ethyne is guided by an understanding of the properties of the molecule. Ethyne is a linear molecule. The best hybrid orbital description is obtained if a 2*s* atomic orbital of carbon mixes with only one of the three 2*p* atomic orbitals. The result is two *sp* hybrid orbitals for each carbon.

UbD Check for Understanding

In what ways is orbital hybridization useful in describing molecules?

Write SO_2 on the board. Ask the following question and instruct students to raise their left hand for VSEPR theory and their right hand for orbital hybridization:

What method would you use to determine the bonding between the sulfur and the oxygen atoms and the shape of the molecule?

ADJUST INSTRUCTION If students are struggling with bonding theories, use a comparison chart to show them the information and the limits of each theory for molecules such as SO_2 and H_2SE.

USE VISUALS Direct students to examine Figure 8.20. Call attention to the sigma bonds formed by the two carbon atoms in ethene. Explain that each carbon atom forms three bonds using three sp^2 orbitals, resulting in a planar molecule with the unhybridized *p* orbital forming lobes of electron density above and below the plane.

DRAW A CONCLUSION Have students compare the shapes of the carbon hybrid orbitals in methane (sp^3), ethene (sp^2), and ethyne molecules (*sp*). Guide students to understand that the key concept in hybridization is that when the atomic orbitals combine to form the hybrid orbitals, they lose their identities and entirely new orbitals are formed. These new orbitals have different characteristics than the ones previously. Emphasize that the shape and orientation of the hybrid orbitals cannot be predicted from the shapes of the combining atomic orbitals. Explain that hybrid orbitals of a particular type (sp^3, sp^2, or *sp*) are identical to one another in terms of shape and bonding properties.

Extend

Connect to HORTICULTURE

Ethene, or ethylene, $H_2C = CH_2$, is a gaseous hormone found in most plants. Many fruits produce ethylene as they ripen. Have students research how the produce industry uses this gaseous hormone to its benefit, and present their findings to the class. *(The produce industry can pick and ship unripe fruit and then rely on the production of ethylene to signal synchronized ripening within the shipment. Then the shipment of fruit is ripe by the time it arrives to the market.)*

Answers

FIGURE 8.20 the regions above and below the carbons

Evaluate

Informal Assessment

Have students compare and contrast the characteristics of sigma and pi bonds. *(A sigma bond is formed when two atomic orbitals combine to form a molecular orbital that is symmetrical along the axis connecting the two atomic nuclei. The electrons tend to be found between the two nuclei. A pi bond is formed from the overlap of two p atomic orbitals. The electrons in a pi bond are found in sausage-shaped regions above and below the bond axis.)* **Ask** How do unshared pairs of electrons influence the shape of a molecule? *(The unshared pairs take up space in the molecule. They repel the bonding pairs, pushing them closer together and decreasing the bond angle.)* Then have students complete the 8.3 Lesson Check.

Reteach

Divide students into pairs to determine the shapes of molecules by means of the VSEPR theory. Assign each pair a number from one to five. Write the following information about the central atoms of five molecules on the board and ask them to determine the geometry of the item that corresponds to their number. Have students begin by writing electron dot structures. Allow students to construct the models as part of their response.

1. four bonding pairs + no nonbonding pairs *(tetrahedral)*;
2. three bonding pairs + one nonbonding pair *(pyramidal)*;
3. two bonding pairs + two nonbonding pairs *(bent)*;
4. two bonding pairs + no nonbonding pair *(linear)*;
5. one bonding pair + any number of nonbonding pairs *(linear)*

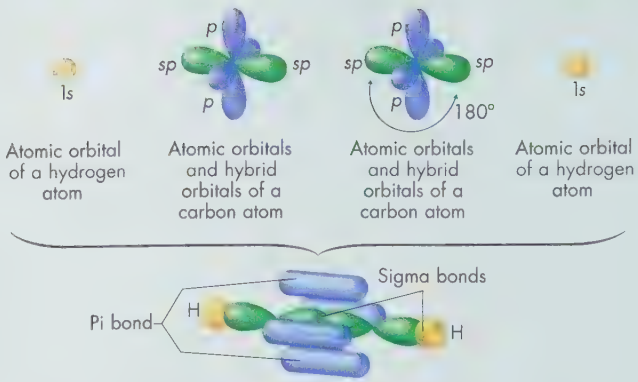

Figure 8.21 Ethyne Molecule
In an ethyne molecule, one *sp* hybrid orbital from each carbon overlaps with a 1*s* orbital of hydrogen to form a sigma bond. The other *sp* hybrid orbital of each carbon overlaps to form a carbon-carbon sigma bond. The two *p* atomic orbitals from each carbon also overlap.
Interpret Diagrams ***How many pi bonds are formed in an ethyne molecule?***

The carbon-carbon sigma-bonding molecular orbital of the ethyne molecule shown in Figure 8.21 forms from the overlap of one *sp* orbital from each carbon. The other *sp* orbital of each carbon overlaps with the 1*s* orbital of each hydrogen, also forming sigma-bonding molecular orbitals. The remaining pair of *p* atomic orbitals on each carbon overlap side by side. They form two pi-bonding molecular orbitals that surround the central carbons. The ten available electrons completely fill five bonding molecular orbitals. The bonding of ethyne consists of three sigma bonds and two pi bonds.

8.3 LessonCheck

21. Review How are atomic and molecular orbitals related?

22. Explain How can the VSEPR theory be used to predict the shapes of molecules?

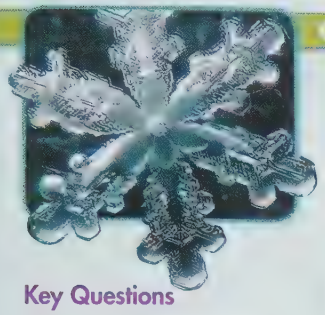
23. Describe How is orbital hybridization useful in describing molecules?

24. Classify What shape would you expect a simple carbon-containing compound to have if the carbon atom has the following hybridizations?
a. sp^2 **b.** sp^3 **c.** *sp*

25. Describe What is a sigma bond? Describe, with the aid of a diagram, how the overlap of two half-filled 1*s* orbitals produces a sigma bond.

26. Explain Use VSEPR theory to predict bond angles in the following covalently bonded molecules. Explain your predictions.
a. methane **b.** ammonia **c.** water

27. Identify How many sigma and how many pi bonds are in an ethyne molecule (C_2H_2)?



28. Classify The BF_3 molecule is planar. The attachment of a fluoride ion to the boron in BF_3, through a coordinate covalent bond, creates the BF_4^- ion. What is the geometric shape of this ion?

Lesson Check Answers

21. When two atoms combine, their atomic orbitals overlap to produce molecular orbitals. An atomic orbital belongs to a particular atom, and a molecular orbital belongs to a molecule as a whole.
22. Each molecule assumes the shape that places valence-electron pairs as far apart as possible.
23. Orbital hybridization provides information about both molecular bonding and molecular shape.
24. **a.** trigonal planar
    b. tetrahedral
    c. linear
25. A sigma bond is formed by the overlap of two orbitals along the axis between two nuclei. See Figure 8.13.
26. a. 109.5° (tetrahedral),
    b. 107° (pyramidal),
    c. 105° (bent)
27. 3 sigma bonds and 2 pi bonds
28. tetrahedral

8.4 Polar Bonds and Molecules

IN C.3.1 Interactions between atoms in ionic and covalent compounds; C.3.2 Formation of ionic and covalent compounds; C.3.3 Chemical bonds and intermolecular attractions

CHEMISTRY & YOU

Q: *How does a snowflake get its shape?* Snow covers approximately 23 percent of Earth's surface. Each individual snowflake is formed from as many as 100 snow crystals. The size and shape of each crystal depends mainly on the air temperature and amount of water vapor in the air at the time the snow crystal forms. In this lesson, you will see how polar covalent bonds in water molecules influence the distinctive geometry of snowflakes.

Key Questions

- ***How do electronegativity values determine the charge distribution in a polar bond?***
- ***How do the strengths of intermolecular attractions compare with the strengths of ionic and covalent bonds?***
- ***Why are the properties of covalent compounds so diverse?***

Vocabulary

- nonpolar covalent bond
- polar covalent bond
- polar bond
- polar molecule
- dipole
- van der Waals forces
- dipole interaction
- dispersion force
- hydrogen bond
- network solid

Bond Polarity

How do electronegativity values determine the charge distribution in a polar bond?

Covalent bonds involve electron sharing between atoms. However, covalent bonds differ in terms of how the bonded atoms share the electrons. The character of the molecule depends on the kind and number of atoms joined together. These features, in turn, determine the molecular properties.

The bonding pairs of electrons in covalent bonds are pulled, as in the tug of war in Figure 8.22, between the nuclei of the atoms sharing the electrons. When the atoms in the bond pull equally (as occurs when identical atoms are bonded), the bonding electrons are shared equally, and each bond formed is a **nonpolar covalent bond.** Molecules of hydrogen (H_2), oxygen (O_2), and nitrogen (N_2) have nonpolar covalent bonds. Diatomic halogen molecules, such as Cl_2, are also nonpolar.

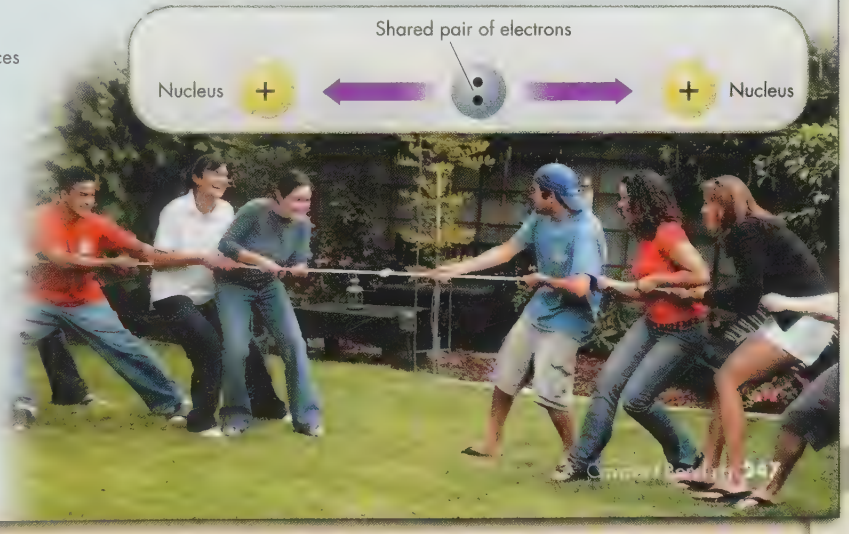


Figure 8.22
Electron Tug of War
The nuclei of atoms pull on the shared electrons, much as the knot in the rope is pulled toward opposing sides in a tug of war.

Focus on ELL

1 CONTENT AND LANGUAGE Write the lesson objectives on the board and read them out loud. Draw students' attention to the word *intermolecular*. Explain that the prefix *inter-* means "between," so the word *intermolecular* means "between molecules." Convey to students that intermolecular forces are different from bonds because these forces do not involve electron donation or sharing.

2 COMPREHENSIBLE INPUT Provide students with a compare and contrast table for them to list important similarities and differences between ionic bonds, covalent bonds, polar covalent bonds, and nonpolar covalent bonds.

LESSON 8.4

Key Objectives

- **8.4.1 DESCRIBE** how electronegativity values determine the charge distribution in a polar molecule.
- **8.4.2 EVALUATE** the strengths of intermolecular attractions compared with the strengths of ionic and covalent bonds.
- **8.4.3 EXPLAIN** why the properties of covalent compounds are so diverse.

PearsonChem.com

Engage

CHEMISTRY & YOU

Have students study the photograph and read the text that opens the lesson. **Ask** What kind of bonds are in the water molecule? *(polar)* **Ask** What is the shape of the snowflake? *(hexagon)*

Build Background

Ask students to recall what they know about other topics that involve polarity, such as magnetism and electricity. Remind students that in cases of electrical polarity, the polarity occurs due to the distribution of positive and negative charges. Explain that, in this lesson, they will see that electrical charge is distributed within a molecule, and how this distribution affects molecular properties.

IN ACADEMIC STANDARDS for SCIENCE

C.3.1 Describe, compare, and contrast the characteristics of the interactions between atoms in ionic and covalent compounds.

C.3.2 Compare and contrast how ionic and covalent compounds form.

C.3.3 Compare and contrast ionic, covalent network, metallic and polar and non-polar molecular crystals with respect to constituent particles, strength of bonds, melting and boiling points, and conductivity; provide examples of each type.

Answers

FIGURE 8.21 Two pi bonds are formed.

Foundations for Reading

BUILD VOCABULARY The vocabulary words *polar*, *nonpolar*, and *dipole* all have the same Latin stem *polus,* meaning "pole." A pole is part of a system, large or small, that has opposite electric or magnetic positions. Discuss familiar examples, such as Earth's magnetic north and south poles, and batteries having positive and negative poles or terminals.

READING STRATEGY As students read the lesson, have them focus on the context of the words *polar*, *nonpolar*, and *dipole*. Have students predict what will be taught in each major section of this lesson. Have students check their predictions after reading.

Explain

Bond Polarity

START A CONVERSATION As a class, predict the relationship, if any, that may exist between the electronegativity differences and the type of bond that exists between two elements. **Ask** What does the term *electronegativity* mean? *(It describes the attraction an atom has for electrons when the atom is in a compound.)* Remind students that electronegativities are calculated values from 0.0 to 4.0 based on the properties of the elements. Refer students back to Table 6.2. **Ask** Which element is the most electronegative? Which is the least? *(Fluorine has an electronegativity value of 4.0; cesium, the element that has the lowest attraction for electrons, has a value of 0.7.)*

USE VISUALS When students use Table 8.4 to solve Sample Problem 8.3, they may be surprised to discover that bonds previously labeled ionic are now categorized as polar covalent. Explain that the reality is that most bonds are neither totally ionic nor totally covalent. Most fall on a continuum from ionic (complete transfer of electrons) to covalent (equal sharing of electrons). In between are polar-covalent bonds in which electrons are displaced more or less toward one atom or the other. Make sure that students understand the two uses of the Greek letter delta. A lowercase delta (δ) is used to denote partial charges; an uppercase delta (Δ) is used to denote a change in a variable.

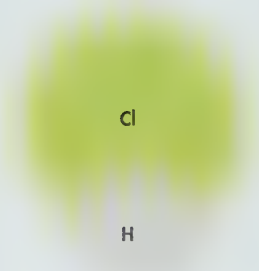

Figure 8.23 Electron Cloud Model of a Polar Bond
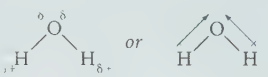
This electron-cloud picture of hydrogen chloride shows that the chlorine atom attracts the electron cloud more than the hydrogen atom does.
Infer ***Which atom is more electronegative, a chlorine atom or a hydrogen atom?***

A **polar covalent bond,** known also as a **polar bond,** is a covalent bond between atoms in which the electrons are shared unequally. **The more-electronegative atom attracts electrons more strongly and gains a slightly negative charge. The less-electronegative atom has a slightly positive charge.** Refer back to Table 6.2 in Chapter 6 to see the electronegativities of some common elements. The higher the electronegativity value, the greater the ability of an atom to attract electrons to itself.



Describing Polar Covalent Bonds In the hydrogen chloride molecule (HCl), hydrogen has an electronegativity of 2.1 and chlorine has an electronegativity of 3.0. These values are significantly different, so the covalent bond in hydrogen chloride is polar. The chlorine atom, with its higher electronegativity, acquires a slightly negative charge. The hydrogen atom acquires a slightly positive charge. The lowercase Greek letter delta (δ) denotes that the atoms in the covalent bond acquire only partial charges, less than 1+ or 1−.

$$\overset{\delta+}{\mathrm{H}}\!-\!\overset{\delta-}{\mathrm{Cl}}$$

The minus sign in this notation shows that chlorine has acquired a slightly negative charge. The plus sign shows that hydrogen has acquired a slightly positive charge. These partial charges are shown as clouds of electron density as illustrated in Figure 8.23. The polar nature of the bond may also be represented by an arrow pointing to the more electronegative atom, as shown here:

$$\mathrm{H}\!\longrightarrow\!\mathrm{Cl}$$

The O—H bonds in a water molecule are also polar. The highly electronegative oxygen partially pulls the bonding electrons away from hydrogen. The oxygen acquires a slightly negative charge. The hydrogen is left with a slightly positive charge.

As shown in Table 8.4, the electronegativity difference between two atoms tells you what kind of bond is likely to form. There is no sharp boundary between ionic and covalent bonds. As the electronegativity difference between two atoms increases, the polarity of the bond increases. If the difference is more than 2.0, the electrons will likely be pulled away completely by one of the atoms. In that case, an ionic bond will form.

Table 8.4
Electronegativity Differences and Bond Types

Electronegativity difference range	Most probable type of bond	Example
0.0–0.4	Nonpolar covalent	H—H (0.0)
0.4–1.0	Moderately polar covalent	$\overset{\delta+}{\mathrm{H}}\!-\!\overset{\delta-}{\mathrm{Cl}}$ (0.9)
1.0–2.0	Very polar covalent	$\overset{\delta+}{\mathrm{H}}\!-\!\overset{\delta-}{\mathrm{F}}$ (1.9)
≥2.0	Ionic	Na·Cl (2.1)

UbD Check for Understanding

The Essential Question **How is the bonding in molecular compounds different from the bonding in ionic compounds?**

Have students to write a brief paragraph comparing and contrasting covalent bonding and polar covalent bonding with ionic bonding.

ADJUST INSTRUCTION If students are confused with bonding concepts, use models to explain all three of the bonding types learned thus far.

Sample Problem 8.3

Identifying Bond Type

Which type of bond (nonpolar covalent, moderately polar covalent, very polar covalent, or ionic) will form between each of the following pairs of atoms?

a. N and H
b. F and F
c. Ca and Cl
d. Al and Cl

1 Analyze **Identify the relevant concepts.** In each case, the pairs of atoms involved in the bonding pair are given. The types of bonds depend on the electronegativity differences between the bonding elements.

2 Solve **Apply concepts to this problem.**

- Identify the electronegativities of each atom using Table 6.2.
- Calculate the electronegativity difference between the two atoms.
- Based on the electronegativity difference, determine the bond type using Table 8.4.

N (3.0), H (2.1); 0.9; moderately polar covalent

F (4.0), F (4.0); 0.0; nonpolar covalent

Ca (1.0), Cl (3.0); 2.0; ionic

Al (1.5), Cl (3.0); 1.5; very polar covalent

29. Identify the bonds between atoms of each pair of elements as nonpolar covalent, moderately polar covalent, very polar covalent, or ionic.
a. H and Br
b. K and Cl
c. C and O
d. Cl and F
e. Li and O
f. Br and Br

30. Place the following covalent bonds in order from least to most polar:
a. H—Cl
b. H—Br
c. H—S
d. H—C

Describing Polar Covalent Molecules The presence of a polar bond in a molecule often makes the entire molecule polar. In a **polar molecule,** one end of the molecule is slightly negative, and the other end is slightly positive. For example, in the hydrogen chloride molecule the partial charges on the hydrogen and chlorine atoms are electrically charged regions, or poles. A molecule that has two poles is called a dipolar molecule, or **dipole.** The hydrogen chloride molecule is a dipole. Look at Figure 8.24. When polar molecules are placed between oppositely charged plates, they tend to become oriented with respect to the positive and negative plates.

Professional Development Note

Molecular Modeling

The widespread availability of fast computers has greatly benefited chemists interested in the shapes of molecules. Molecular modeling computer programs are becoming an important tool in the pharmaceutical industry for designing drugs. These programs create models of molecules composed of thousands of atoms. Using a special viewing apparatus, chemists can see three-dimensional representations of complex molecules. Models can be rotated, reduced or enlarged, and cut into pieces. Through computer technology called virtual reality, a chemist can virtually get inside a molecular structure to examine it from every possible angle.

Explore

Class Activity

PURPOSE Students experience the attraction of opposite poles of a magnet as an experience similar to the attraction of opposite electric charges.

MATERIALS magnets, iron filings, cardboard

PROCEDURE Place some iron filings on a cardboard. Hold a magnet under the cardboard and move it to create patterns. Allow students to handle magnets and feel the pull when north and south poles are close. Have students write a sentence relating the experience to polar molecules.

Sample Practice Problems

Which type of bond (nonpolar, covalent, moderately covalent, or ionic) will form between each of the following pairs of ions?

A. C and H *(nonpolar covalent)*
B. Be and F *(ionic)*
C. Si and Cl *(very polar covalent)*

Answers

FIGURE 8.23 chlorine

b. ionic
c. moderately to very polar covalent
d. moderately to very polar covalent
e. ionic
f. nonpolar covalent

30. c and d (tie), b, a

Explain

Describing Polar Covalent Bonds

INTERPRET DIAGRAMS Draw diagrams of molecules on the board or overhead projector. Have the class use electronegativity values to determine which element has the partial positive charge and which has the partial negative charge. Explain how the attraction of electrons can be described with a vector. Point out that the shape of the molecule determines the direction of the vector. If the sum of the vectors acting on the central atom in one direction is cancelled by the sum of the vectors acting in the other direction, the molecule has no dipole. If they do not cancel, the molecule is polar.

Explore

Teacher Demo

PURPOSE Students observe what happens to polar molecules when they are placed near positively charged materials.

MATERIALS 2 burets, 2 beakers, ring stand, buret clamps, turpentine, water, rubber rod, glass rod, fur cloth

SAFETY Wear safety goggles and gloves.

PROCEDURE Attach two burets to a ring stand. Fill one with water and the other with turpentine. Place a beaker under each. CAUTION! Turpentine is an irritant. Rub a rubber rod with a fur cloth to charge it negatively. Bring the rod near the open end of the water-containing buret as you slowly open the stopcock. Have students observe the behavior of the water. Repeat the procedure using turpentine. Then repeat using a charged glass rod for both liquids.

EXPECTED OUTCOMES The polar water molecules are attracted to both negatively and positively charged materials, but the nonpolar turpentine molecules are not attracted to either.

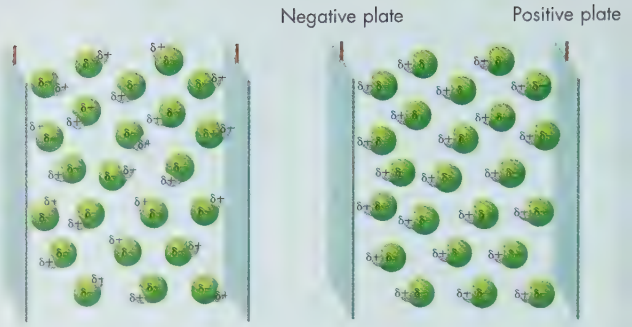

Figure 8.24
Polar Molecules in an Electric Field
When polar molecules, such as HCl, are placed in an electric field, the slightly negative ends of the molecules become oriented toward the positively charged plate, and the slightly positive ends of the molecules become oriented toward the negatively charged plate.
Predict ***What would happen if, instead, carbon dioxide molecules were placed between the plates? Why?***

Electric field is absent. Polar molecules orient randomly.

Electric field is on. Polar molecules line up.

See Polar Molecules animated online.

The effect of polar bonds on the polarity of an entire molecule depends on the shape of the molecule and the orientation of the polar bonds. A carbon dioxide molecule, for example, has two polar bonds and is linear.

$$\overrightarrow{O}=C=\overrightarrow{O}$$

Note that the carbon and oxygens lie along the same axis. Therefore, the bond polarities cancel because they are in opposite directions. Carbon dioxide is thus a nonpolar molecule, despite the presence of two polar bonds.

The water molecule also has two polar bonds. However, the water molecule is bent rather than linear. Therefore, the bond polarities do not cancel and a water molecule is polar.

Attractions Between Molecules

How do the strengths of intermolecular attractions compare with ionic and covalent bonds?

Molecules can be attracted to each other by a variety of different forces. **Intermolecular attractions are weaker than either ionic or covalent bonds.** Nevertheless, you should not underestimate the importance of these forces. Among other things, these attractions are responsible for determining whether a molecular compound is a gas, a liquid, or a solid at a given temperature.

Van der Waals Forces The two weakest attractions between molecules are collectively called **van der Waals forces,** named after the Dutch chemist Johannes van der Waals (1837–1923). Van der Waals forces consist of dipole interactions and dispersion forces.

Dipole interactions occur when polar molecules are attracted to one another. The electrical attraction involved occurs between the oppositely charged regions of polar molecules, as shown in Figure 8.25. The slightly negative region of a polar molecule is weakly attracted to the slightly positive region of another polar molecule. Dipole interactions are similar to, but much weaker than, ionic bonds.

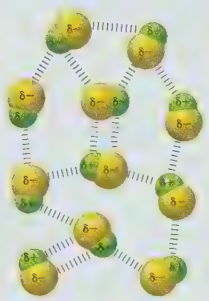

Figure 8.25 Dipole Interactions
Polar molecules are attracted to one another by dipole interactions, a type of van der Waals force.

Professional Development Note

Intermolecular Adjustments

The Dutch physicist Johannes van der Waals (1837–1923) surmised that real gas behavior could not be described exactly by the ideal gas law because the law assumes that gas molecules have no volume and that no attractive forces exist between gas molecules. Van der Waals adjusted the ideal gas equation by introducing two factors: one to take cognizance of the real volume of gas molecules; the other to account for intermolecular forces between molecules. For his work in developing an understanding of intermolecular attractions, he was awarded the Nobel Prize in Physics in 1910, and van der Waals forces, the weak attractive forces he had been studying, were named in his honor.

250 Chapter 8 • Lesson 4

Dispersion forces, the weakest of all molecular interactions, are caused by the motion of electrons. They occur even between nonpolar molecules. When the moving electrons happen to be momentarily more on the side of a molecule closest to a neighboring molecule, their electric force influences the neighboring molecule's electrons to be momentarily more on the opposite side. This shift causes an attraction between the two molecules similar to, but much weaker than, the force between permanently polar molecules. The strength of dispersion forces generally increases as the number of electrons in a molecule increases. The halogen diatomic molecules, for example, attract each other mainly by means of dispersion forces. Fluorine and chlorine have relatively few electrons and are gases at ordinary room temperature and pressure because of their especially weak dispersion forces. The larger number of electrons in bromine generates larger dispersion forces. Bromine molecules therefore attract each other sufficiently to make bromine a liquid at ordinary room temperature and pressure. Iodine, with a still larger number of electrons, is a solid at ordinary room temperature and pressure.

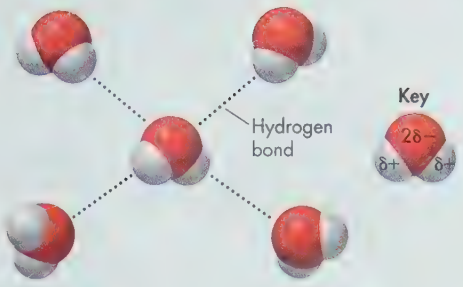

Figure 8.26
Hydrogen Bonds in Water
The strong hydrogen bonding between water molecules accounts for many properties of water, such as the fact that water is a liquid rather than a gas at room temperature.

Hydrogen Bonds The dipole interactions in water produce an attraction between water molecules. Each O—H bond in the water molecule is highly polar, and the oxygen acquires a slightly negative charge because of its greater electronegativity. The hydrogens in water molecules acquire a slightly positive charge. The positive region of one water molecule attracts the negative region of another water molecule, as illustrated in Figure 8.26. This attraction between the hydrogen of one water molecule and the oxygen of another water molecule is strong compared to other dipole interactions. This relatively strong attraction, which is also found in hydrogen-containing molecules other than water, is called a hydrogen bond. Figure 8.26 illustrates hydrogen bonding in water.

Hydrogen bonds are attractive forces in which a hydrogen covalently bonded to a very electronegative atom is also weakly bonded to an unshared electron pair of another electronegative atom. This other atom may be in the same molecule or in a nearby molecule. Hydrogen bonding always involves hydrogen. It is the only chemically reactive element with valence electrons that are not shielded from the nucleus by other electrons.

Remember that for a hydrogen bond to form, a covalent bond must already exist between a hydrogen atom and a highly electronegative atom, such as oxygen, nitrogen, or fluorine. The combination of this strongly polar bond and the lack of shielding effect in a hydrogen atom is responsible for the relative strength of hydrogen bonds. A hydrogen bond has about 5 percent of the strength of an average covalent bond. Hydrogen bonds are the strongest of the intermolecular forces. They are extremely important in determining the properties of water and biological molecules such as proteins. Figure 8.27 shows how the relatively strong attractive forces between water molecules allows the water strider to sit on the surface of the water.

CHEMISTRY & YOU

Q: *How does a snowflake get its shape?*

Figure 8.27 Walking on Water
The strong attractions between water molecules allow this water strider to "walk" on water instead of sinking into the water.

Explain

Attractions Between Molecules

APPLY CONCEPTS Discuss how the sharing of electrons binds atoms into molecules. Point out that if no other forces were present, all covalently bonded molecules would be gases at any temperature because no attractive forces would tend to pull them together to form a liquid or solid. Explain, however, that forces such as van der Waals forces and hydrogen bonding do exist between covalently bonded molecules.

CHEMISTRY & YOU A snowflake's shape is influenced by the intermolecular forces of the water molecules that make up the snowflake. Hydrogen bonds cause the water molecules to align themselves so the attractive forces are maximized.

DRAW A DIAGRAM Construct a concept map using the following terms: intermolecular attractions, van der Waals forces, dispersion forces, dipole interactions, and hydrogen bonding. Use the concept map to introduce and discuss each force in detail. Use the halogen family to demonstrate dispersion forces, carbon dioxide to discuss dipole interactions, and water to discuss hydrogen bonding. **Ask** Why does He have a lower boiling point than Rn? *(Rn has more electrons, so its intermolecular forces are stronger than those of He.)* Point out that hydrogen bonds only occur between molecules in which hydrogen is bonded to a strongly electronegative atom such as nitrogen, oxygen, or fluorine. Because living systems contain molecules rich in oxygen and nitrogen, hydrogen bonding plays an important role in the chemistry of living systems. Hydrogen bonding also explains many of the physical properties of water.

Differentiated Instruction

L1 LESS PROFICIENT READERS Use a three-dimensional software program or Internet-based animations to help students predict the polarity and the type of force between molecules.

ELL ENGLISH LANGUAGE LEARNERS Clarify students' understanding of the word *force* as it relates to this lesson. Make sure they are not looking for a quantitative value as they might have learned from physics or mathematics class.

L3 ADVANCED STUDENTS As a preparation for later chapters, have students research the effects of bond polarity on solubility.

Intermolecular Attractions and Molecular Properties

Teacher Demo

PURPOSE Students see how hydrogen bonding affects the surface tension and viscosity of fluids.

MATERIALS 4 300-mL stoppered flasks, each containing 100 mL of one of these liquids: glycerol, ethylene glycol, water, ethanol

PROCEDURE Gently rotate one of the flasks so that its contents begin to swirl. Have students measure the time interval between your ceasing to rotate the bottle and the disappearance of the swirling vortex. Repeat the procedure for each fluid. Be sure to rotate each flask the same number of times.

EXPECTED OUTCOMES From longest time to shortest: ethanol, water, ethylene glycol, and glycerol. Point out that hydrogen bonding increases a liquid's surface tension and viscosity. Thus, liquids with a relatively high degree of hydrogen bonding generally stop swirling more quickly. Have students order the fluids according to increasing hydrogen bonding. *(ethanol, water, ethylene glycol, glycerol)* Show the structural formulas of the compounds to demonstrate the origins of the hydrogen bonding.

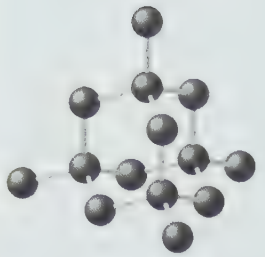

Figure 8.28 Diamond
Diamond is a network-solid form of carbon. Diamond has a three-dimensional structure, with each carbon at the center of a tetrahedron.

Intermolecular Attractions and Molecular Properties

Why are the properties of covalent compounds so diverse?

At room temperature, some compounds are gases, some are liquids, and some are solids. The physical properties of a compound depend on the type of bonding it displays—in particular, on whether it is ionic or covalent. A great range of physical properties occurs among covalent compounds. **The diversity of physical properties among covalent compounds is mainly because of widely varying intermolecular attractions.**

The melting and boiling points of most compounds composed of molecules are low compared with those of ionic compounds. In most solids formed from molecules, only the weak attractions between molecules need to be broken. However, a few solids that consist of molecules do not melt until the temperature reaches 1000°C or higher, or they decompose without melting at all. Most of these very stable substances are **network solids** (or network crystals), solids in which all of the atoms are covalently bonded to each other. Melting a network solid would require breaking covalent bonds throughout the solid.

Diamond is an example of a network solid. As shown in Figure 8.28, each carbon atom in a diamond is covalently bonded to four other carbons, interconnecting carbon atoms throughout the diamond. Cutting a diamond requires breaking a multitude of these bonds. Diamond does not melt; rather, it vaporizes to a gas at 3500°C and above.

Silicon carbide, with the formula SiC and a melting point of about 2700°C, is also a network solid. Silicon carbide is so hard that it is used in grindstones and as an abrasive. It is also used as a coating on materials that are exposed to high temperatures, as in Figure 8.29. The molecular structures of silicon carbide and diamond are similar to each other. You can think of samples of diamond, silicon carbide, and other network solids as single molecules.

Figure 8.29 Silicon Carbide
Surfaces are coated with silicon carbide to make products that are non-adhesive and resistant to extreme temperature, abrasions, and corrosion.

UbD Check for Understanding

The Essential Question **What factors affect molecular properties?**

Ask students to summarize why molecular properties among covalent compounds are not all the same. Summaries may be verbal or written.

ADJUST INSTRUCTION Direct students to review Table 8.4 and discuss why and how intermolecular forces allow for such diversity among covalent compounds.

Table 8.5 summarizes some of the characteristic differences between ionic and covalent (molecular) substances. Note that ionic compounds have higher melting points than molecular compounds. Ionic compounds also tend to be soluble in water.

Table 8.5

Characteristics of Ionic and Molecular Compounds

Characteristic	Ionic compound	Molecular compound
Representative unit	Formula unit	Molecule
Bond formation	Transfer of one or more electrons between atoms	Sharing of electron pairs between atoms
Type of elements	Metallic and nonmetallic	Nonmetallic
Physical state	Solid	Solid, liquid, or gas
Melting point	High (usually above 300°C)	Low (usually below 300°C)
Solubility in water	Usually high	High to low
Electrical conductivity of aqueous solution	Good conductor	Poor to nonconducting

8.4 LessonCheck

31. **Explain** How do electronegativity values determine the charge distribution in a polar covalent bond?

32. **Compare** How do the strengths of intermolecular attractions compare to the strengths of ionic bonds and covalent bonds?

33. **Explain** Explain why network solids have high melting points.

34. **Explain** Explain this statement: Not every molecule with polar bonds is polar. Use CCl_4 as an example.

35. **Draw** Draw the electron dot structure for each molecule. Identify polar covalent bonds by assigning slightly positive (δ+) and slightly negative (δ−) symbols to the appropriate atoms.

a. HOOH **c.** HBr

b. BrCl **d.** H_2O

36. **Compare** How does a network solid differ from most other covalent compounds?

37. What happens when polar molecules are between oppositely charged metal plates?

BIGIDEA

BONDING AND INTERACTIONS

38. Explain how dipole interactions and dispersion forces are related. First, explain what produces the attractions between polar molecules. Then, explain what produces dispersion forces between molecules. Identify what is similar and what is different in the two mechanisms of intermolecular attraction.

Evaluate

Informal Assessment

Have students use their knowledge of bonding to account for the generally low melting points of covalent compounds. *(Intermolecular attractions between covalent compounds are generally not as strong as ionic bonds.)* Then have students complete the 8.4 Lesson Check.

Reteach

Help students list the types of intermolecular attractions that exist between molecules. Give examples of compounds that would fit into each category. Encourage students to continue using their concept maps to organize the chapter material.

Lesson Check Answers

31. The more electronegative atom attracts electrons more strongly and gains a partial negative charge. The less electronegative atom has a partial positive charge.

32. Intermolecular attractions are weaker than either ionic or covalent bonds.

33. Melting a network solid requires breaking covalent bonds throughout the solid.

34. The atoms in CCl_4 are oriented so that the bond polarities cancel.

35. **a.** $\overset{\delta+}{H}:\overset{\delta-}{\ddot{O}}:\overset{\delta-}{\ddot{O}}:\overset{\delta+}{H}$

b. $:\overset{\delta+}{\ddot{B}r}:\overset{\delta-}{\ddot{C}l}:$

c. $\overset{\delta+}{H}:\overset{\delta-}{\ddot{B}r}:$

d. $\overset{\delta+}{H}:\overset{\delta-}{\ddot{O}}:\overset{\delta+}{H}$

36. The atoms in a network solid are covalently bonded in a large array (or crystal), which can be thought of as a single molecule.

37. Polar molecules tend to become oriented with respect to the positive and negative plates.

38. **BIG**IDEA In dipole interactions, the slightly positive end of a polar molecule attracts the slightly negative end of another polar molecule. Dispersion forces arise from the movement of electrons in any molecule, polar or nonpolar. If the electrons in one molecule happen to be momentarily more on one side, the electrons in a neighboring molecule can be repulsed. Weak attractions result between the temporary dipoles.

Explore

Small-Scale Lab

OBJECTIVE After completing this activity, students will be able to infer differences in polarity by observing the chromatographic separation of food dyes.

PREP TIME 15 minutes

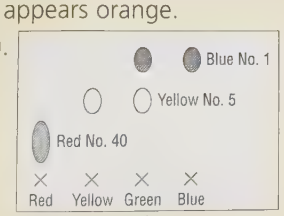
CLASS TIME 30 minutes

ADVANCED PREP

- To prepare 0.1% NaCl, dissolve 1.0 g NaCl in 1.0 L water.
- Jelly beans and small candy-coated chocolates are good sources of food dyes. Dissolve a package of unsweetened powdered soft drink in a small amount of water and have students use toothpicks to spot this solution on chromatography paper.
- Coffee filters can substitute for chromatography paper, but caution students not to overload their samples.

TEACHING TIPS Tell students to position the chromatography paper so that the lower end of the paper is in the liquid but the spots of dye are above the surface. A similar, more complete lab on chromatography is found in the Small-Scale Laboratory Manual.

EXPECTED OUTCOME In order of increasing speed of travel: red, yellow, and blue. Green separated into yellow and blue.



YOU'RE THE CHEMIST!

1. Wet candy, blot to remove excess water, press onto chromatography paper, and develop in 0.1% NaCl.
2. Place spots on chromatography paper. Develop in NaCl solution.
3. Use a toothpick to place spots of powdered drink solutions.
4. Rubbing alcohol moves more slowly and gives slightly better separation.
5. With some papers, the positions of Blue No. 1 and Yellow No. 5 are reversed.

ADVANCED LEARNERS Encourage students to investigate how different carrier fluids affect the movement of the four dyes. For example, they might try pure water or ethanol.

ANALYZE

1. Red, yellow, and blue are pure.
2. Green is Yellow No. 5 plus Blue No. 1.
3. Blue No. 1; Red No. 40 (No. 3 if supplies haven't been used up); Yellow No. 5 or Yellow No. 6 if the dye appears orange.
4. See the drawing.
5. Blue is the most polar; red, the least polar.

Small-Scale Lab

Paper Chromatography of Food Dyes

Purpose

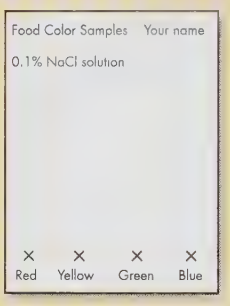
To use paper chromatography to separate and identify food dyes in various samples

Materials

- pencil
- ruler
- scissors
- toothpicks
- 4 different colors of food coloring
- plastic cup
- 0.1% NaCl solution
- chromatography paper

Procedure

Cut a 5 cm × 10 cm strip of chromatography paper and label it with a pencil, as shown below. Use a different toothpick to place a spot of each of the four food colors on the Xs on your chromatography paper. Allow the spots to dry for a few minutes. Fill the plastic cup so its bottom is just covered with the solvent (0.1% NaCl solution). Wrap the chromatography paper around a pencil. Remove the pencil and place the chromatography paper, color-spot side down, in the solvent. When the solvent reaches the top of the chromatography paper, remove the paper and allow it to dry.



Analysis

Using your experimental data, record the answers to the following questions below your data table.

1. If a food-color sample yields a single streak or spot, it is usually a pure compound. Which food colors consist of pure compounds?

2. Which food colors are mixtures of compounds?

3. Food colors often consist of a mixture of three colored dyes: Red No. 40, Yellow No. 5, and Blue No. 1. Read the label on the food-color package. Which dyes do your food-color samples contain?

4. Identify each spot or streak on your chromatogram as Red No. 40, Yellow No. 5, or Blue No. 1.

5. Paper chromatography separates polar covalent compounds on the basis of their relative polarities. The dyes that are the most polar migrate the fastest and appear at the top of the paper. Which dye is the most polar? Which dye is the least polar?

You're the Chemist

The following small-scale activities allow you to develop your own procedures and analyze the results.

1. Design an Experiment Design and carry out an experiment to identify the dyes in various colored candies.

2. Design an Experiment Design and carry out an experiment to identify the dyes in various colored markers using the paper chromatography method.

3. Design an Experiment Design and carry out an experiment to identify the dyes in various colored powdered drinks using the paper chromatography method.

4. Analyze Data Use different solvents, such as 2-propanol (rubbing alcohol), vinegar, and ammonia, to separate food colors. Does the choice of solvent affect the results?

5. Analyze Data Explore the effect of different papers on your results. Try paper towels, notebook paper, and coffee filters. Report your results. Examine the relative positions of Blue No. 1 and Yellow No. 5. What do you observe?

Focus on ELL

4 LANGUAGE PRODUCTION Have students work in groups of four to complete the lab. Make sure each group has ELLs of varied language proficiencies, so that more proficient students can help less proficient ones. Have students work according to their proficiency level.

BEGINNING: LOW/HIGH Paraphrase each step of the lab orally and group students with higher language proficiency partners to help with the written answers.

INTERMEDIATE: LOW/HIGH Ask students to read the procedure and then break it down into numbered steps that are easier for them to follow.

ADVANCED: LOW/HIGH Have students help students with lower proficiencies with the written answers and predictions.

8 Study Guide

BIG IDEA

BONDING AND INTERACTIONS

In molecular compounds, bonding occurs when atoms share electrons. In ionic compounds, bonding occurs when electrons are transferred between atoms. Shared electrons and the valence electrons that are not shared affect the shape of a molecular compound, as the valence electrons stay as far apart from each other as possible. The molecular properties of a molecule are affected by intermolecular attractions.

8.1 Molecular Compounds

- A molecular formula shows how many atoms of each element a substance contains.
- The representative unit of a molecular compound is a molecule. For an ionic compound, the representative unit is a formula unit.

- covalent bond (223)
- molecule (223)
- diatomic molecule (223)
- molecular compound (223)
- molecular formula (223)

8.2 The Nature of Covalent Bonding

- In covalent bonds, electron sharing occurs so that atoms attain the configurations of noble gases.
- In a coordinate covalent bond, the shared electron pair comes from a single atom.
- The octet rule is not satisfied in molecules with an odd number of electrons and in molecules in which an atom has less, or more, than a complete octet of valence electrons.
- A large bond dissociation energy corresponds to a strong covalent bond.
- Chemists use resonance structures to envision the bonding in molecules that cannot be adequately described by a single structural formula.

- single covalent bond (226)
- structural formula (227)
- unshared pair (227)
- double covalent bond (230)
- triple covalent bond (230)
- coordinate covalent bond (232)
- polyatomic ion (232)
- bond dissociation energy (236)
- resonance structure (237)

8.3 Bonding Theories

- Just as an atomic orbital belongs to a particular atom, a molecular orbital belongs to a molecule as a whole.
- In order to explain the three-dimensional shape of molecules, scientists use the valence-shell electron-pair repulsion theory (VSEPR theory).
- Orbital hybridization provides information about both molecular bonding and molecular shape.

- molecular orbital (240)
- bonding orbital (240)
- sigma bond (240)
- pi bond (241)
- tetrahedral angle (242)
- VSEPR theory (242)
- hybridization (244)

8.4 Polar Bonds and Molecules

- When different atoms bond, the more-electronegative atom attracts electrons more strongly and acquires a slightly negative charge.
- Intermolecular attractions are weaker than either an ionic or covalent bond.
- The diversity of physical properties among covalent compounds is mainly because of widely varying intermolecular attractions.

- nonpolar covalent bond (247)
- polar covalent bond (248)
- polar bond (248)
- polar molecule (249)
- dipole (249)
- van der Waals forces (250)
- dipole interaction (250)
- dispersion force (251)
- hydrogen bond (251)
- network solid (252)

Review and Assessment Resources

PROBLEM SETS Have students practice more problems using the Chapter 8 Online Problem Set.

MATH SKILLS Have struggling students practice manipulating algebraic equations using the MathXL learning module.

Study Tip

SWITCH TASKS When you feel yourself losing focus, switch the type of task you are working on, the subject that you are studying, or the environment you are in. Take a break and walk around a bit when you are no longer being productive.

Focus on ELL

5 ASSESS UNDERSTANDING Read the Big Idea paragraph out loud, one sentence at a time. Have students point to the lesson review that corresponds to each sentence. Encourage students to use the Study Guide to prepare for the assessment.

BEGINNING: LOW/HIGH Give each student a copy of the Study Guide. Ask them to make a check mark next to the content they understand and circle the content they do not understand. Create simple matching assessments to assess only the content they circle.

INTERMEDIATE: LOW/HIGH Explain the meaning of common words that appear on multiple-choice questions, such as *likely*, *most*, *probably*, and *best*. Orally pose some questions using these words.

ADVANCED: LOW/HIGH Explain how to interpret multiple-choice questions that use the word *not*. Orally pose some "not" type questions as practice.

UbD Performance Tasks

THREE FOR THREE-D: Have students create three-dimensional models of three different molecular compounds. Each molecule should have a different shape and each part of the molecule should be labeled accurately.

WHAT DID IT? Create a storybook, including pictures, where the beginning of the story is the CHEMystery, "What's that alarm?" Finish the story by explaining what the mystery substance was, how it was created, how the carbon and oxygen were bonded, and how the family prevented the substance from returning into the house.

ASSESSMENT

Evaluate

Answers

LESSON 8.1

39. ionic

40. **a.** 6 C, 8 H, 6 O **b.** 12 C, 22 H, 11 O **c.** 7 C, 5 H, 3 N, 6 O

41. Nitrogen and oxygen achieve stability as diatomic molecules. Argon exists as individual atoms because it has a stable noble-gas electron configuration.

42. Molecular formulas show the number and kind of atoms in the molecule; structural formulas show the covalent bonds in addition to the number and kind of atoms.

43. b., c., e.

LESSON 8.2

44. Neon has an octet of electrons. A chlorine atom achieves an octet by sharing an electron with another chlorine atom.

45. **a.** ionic **b.** ionic **c.** covalent **d.** covalent

46. Ionic bonds depend on electrostatic attraction between ions. Covalent bonds depend on electrostatic attraction between shared electrons and nuclei of combining atoms.

47. A double covalent bond has four shared electrons (two bonding pairs); a triple covalent bond has six shared electrons (three bonding pairs).

48. One atom contributes both electrons to a coordinate covalent bond, as in CO.

49. **a.** $:\ddot{I}-\ddot{I}:$ **b.** $:\ddot{F}-\ddot{O}-\ddot{F}:$ **c.** $H-\ddot{S}-H$ **d.** $\begin{matrix} & :\ddot{I}: & \\ :\ddot{I}- & \ddot{N} & -\ddot{I}: \\ & :\ddot{I}: & \end{matrix}$

50. An unshared pair of electrons is needed for a coordinate covalent bond. There are no unshared pairs in compounds with only C-H and C-C bonds.

51. $\left[:\ddot{S}-C\equiv N:\right]^-$

52. $\left[\begin{matrix} & \ddot{O} & \\ & \| & \\ :\ddot{O}- & C & -H \end{matrix}\right]^-$

53. $\left[:\ddot{O}-\dot{N}=\ddot{O}:\right]^- \leftrightarrow \left[:\ddot{O}=\dot{N}-\ddot{O}:\right]^-$

54. b and c; assuming only single bonds, the P and S atoms each have 10 valence electrons.

55. Bond dissociation energy is defined as the energy needed to break one covalent bond.

56. Increasing bond dissociation energy is linked to lower chemical reactivity.

57. **a.** 4 **b.** 8 **c.** 6 **d.** 2 **e.** 2

58. Check students' dot structures.

LESSON 8.3

59. A pi bond is formed by the side-by side overlap of two half-filled p atomic orbitals to produce a pi molecular orbital. In a pi bond, the bonding electrons are most likely to be found in sausage-shaped regions above and below the bond. See Figure 8.15.

8 Assessment

* Solutions appear in Appendix E

Lesson by Lesson

8.1 Molecular Compounds

39. The melting point of a compound is 1240°C. Is this compound most likely an ionic compound or a molecular compound?

40. Identify the number and kinds of atoms present in a molecule of each compound.
- **a.** ascorbic acid (vitamin C), $C_6H_8O_6$
- **b.** sucrose (table sugar), $C_{12}H_{22}O_{11}$
- **c.** trinitrotoluene (TNT), $C_7H_5N_3O_6$

41. Which of the following gases in Earth's atmosphere would you expect to find as molecules and which as individual atoms? Explain.
- **a.** nitrogen
- **b.** oxygen
- **c.** argon

42. Describe the differences between molecular formulas and structural formulas for molecular compounds.

43. Identify the phrases that generally apply to molecular compounds.
- **a.** contain metals and nonmetals
- **b.** are often gases or liquids
- **c.** have low melting points
- **d.** contain ionic bonds
- **e.** use covalent bonding

8.2 The Nature of Covalent Bonding

44. Explain why neon is monatomic but chlorine is diatomic.

45. Classify the following compounds as ionic or covalent:
- **a.** $MgCl_2$ **c.** H_2O
- **b.** Na_2S **d.** H_2S

46. Describe the difference between an ionic and a covalent bond.

47. How many electrons do two atoms in a double covalent bond share? How many in a triple covalent bond?

***48.** Characterize a coordinate covalent bond and give an example.

49. Draw plausible electron dot structures for the following substances. Each substance contains only single covalent bonds.
- **a.** I_2 **c.** H_2S
- **b.** OF_2 **d.** NI_3

***50.** Explain why compounds containing C—N and C—O single bonds can form coordinate covalent bonds with H^+ but compounds containing only C—H and C—C single bonds cannot.

51. Draw the electron dot structure of the polyatomic thiocyanate anion (SCN^-).

52. Draw the electron dot structure for the hydrogen carbonate ion (HCO_3^-). Carbon is the central atom, and hydrogen is attached to oxygen in this polyatomic anion.

53. Using electron dot structures, draw at least two resonance structures for the nitrite ion (NO_2^-). The oxygens in NO_2^- are attached to the nitrogen.

***54.** Which of these compounds contain elements that do not follow the octet rule? Explain.
- **a.** NF_3 **c.** SF_4
- **b.** PCl_2F_3 **d.** SCl_2

55. Explain what is meant by *bond dissociation energy.*

56. What is the relationship between the magnitude of a molecule's bond dissociation energy and its expected chemical reactivity?

57. How many electrons must the atoms of the elements below share with other atoms in covalent bonding to achieve an octet of electrons?
- **a.** S **c.** N **e.** I
- **b.** C **d.** Br

***58.** Draw the electron dot structures for each of these molecules.
- **a.** NH_3 **c.** H_2O_2
- **b.** BrCl **d.** SiH_4

8.3 Bonding Theories

59. What is a pi bond? Describe, with the aid of a diagram, how the overlap of two half-filled *p* atomic orbitals produces a pi bond.

*60. Use VSEPR theory to predict the shapes of the following compounds:

a. CO_2 c. SO_3 e. CO
b. $SiCl_4$ d. SCl_2 f. H_2Se

61. The molecule CO_2 has two carbon–oxygen double bonds. Describe the bonding in the CO_2 molecule, which involves hybridized orbitals for carbon and oxygen.

62. What type of bonding orbital is always formed between hydrogen and another atom in a covalent compound?

*63. What types of hybrid orbitals are involved in the bonding of the carbon atoms in the following molecules?

a. CH_4
b. $H_2C{=}CH_2$
c. $HC{\equiv}CH$
d. $N{\equiv}C{-}C{\equiv}N$

8.4 Polar Bonds and Molecules

64. How must the electronegativities of two atoms compare if a covalent bond between them is to be polar?

*65. The bonds between the following pairs of elements are covalent. Arrange them according to polarity, listing the most polar bond first.

a. H—Cl c. H—F e. H—H
b. H—C d. H—O f. S—Cl

66. What is a hydrogen bond?

67. Depict the hydrogen bonding between two ammonia molecules and between one ammonia molecule and one water molecule.

68. Why do compounds with strong intermolecular attractive forces have higher boiling points than compounds with weak intermolecular attractive forces?

*69. Use Table 8.3 to determine how many kilojoules are required to dissociate all the C—H bonds in 1 mol of methane (CH_4).

70. Which of these molecules is least likely to form a hydrogen bond with a water molecule?

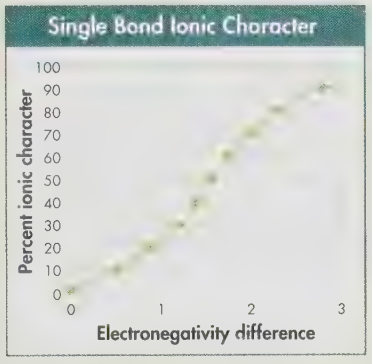
a. NH_3 c. HF
b. CH_3Cl d. H_2O_2

Understand Concepts

*71. Devise a hybridization scheme for PCl_3 and predict the molecular shape based on this scheme.

72. The chlorine and oxygen atoms in thionyl chloride ($SOCl_2$) are bonded directly to the sulfur. Draw an acceptable electron dot structure for thionyl chloride.

73. Explain why each electron dot structure is incorrect. Replace each structure with one that is more acceptable.



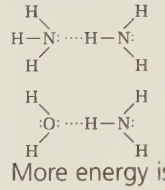
a. $[:C{::}N:]^-$

b. 

74. Use VSEPR theory to predict the geometry of each of the following:

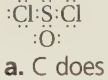
a. $SiCl_4$ c. CCl_4
b. CO_3^{2-} d. SCl_2

75. The following graph shows how the percent ionic character of a single bond varies according to the difference in electronegativity between the two elements forming the bond. Answer the following questions, using this graph and Table 6.2.



a. What is the relationship between the percent ionic character of single bonds and the electronegativity difference?
b. What electronegativity difference will result in a bond with a 50 percent ionic character?
c. Estimate the percent ionic character of the bonds formed between (1) lithium and oxygen, (2) nitrogen and oxygen, (3) magnesium and chlorine, and (4) nitrogen and fluorine.

ASSESSMENT



Answers

60. a. linear b. tetrahedral c. trigonal planar
d. bent e. linear f. bent
61. The 2*s* and the 2*p* orbitals form two *sp* hybrid orbitals on the carbon atom. One *sp* hybrid orbital forms a sigma bond between the carbon atom and each oxygen atom. *Pi* bonds between each oxygen atom and the carbon are formed by the unhybridized 2*p* orbitals.
62. sigma bonding orbital
63. a. sp^3 b. sp^2 c. *sp* d. *sp*

LESSON 8.4

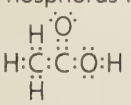
64. The electronegativities of the two atoms will differ by about 0.4 to 2.0.
65. c, d, a, f, b, e
66. A hydrogen bond is formed by an electrostatic interaction between a hydrogen atom that is covalently bonded to an electronegative atom, and an unshared electron pair of a nearby atom.
67. 
68. More energy is required to separate the molecules.
69. 1572 kJ
70. b. CH_3Cl

UNDERSTAND CONCEPTS

71. The 3*s* and three 3*p* orbitals of phosphorus hybridize to form four sp^3 atomic orbitals. The resulting shape is pyramidal with a bond angle of 107 between the sigma bonds.
72. 
73. a. C does not have an octet. $[:C{::}N:]^-$
b. One F has more than an octet. 
74. a. tetrahedral, 109.5
b. trigonal planar, 120
c. tetrahedral, 109.5
d. bent, 105
75. a. The percent ionic character increases as the difference in electronegativities increases.
b. 1.6
c. (1) 85% (2) 10% (3) 62% (4) 23%

ASSESSMENT

Evaluate



Answers

76. **a.** 109.5
b. 120
c. 180

77. **a.** trigonal planar
b. linear
c. pyramidal
d. tetrahedral

78. **a.** Phosphorus in PBr5 has 10 valence electrons.

79. **a.**

b. No, the molecule contains one carbon-oxygen double bond and one carbon-oxygen single bond.
c. polar bond
d. Yes, it has polar oxygen atoms at one end of the molecule and a nonpolar CH_3– group at the opposite end.

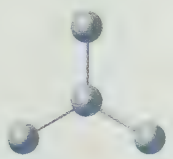
THINK CRITICALLY

80. C, O, H, S, N, F, Cl: These elements are all nonmetals.

81. Answers will vary. Table 8.3 suggests there is no clear difference. The student's argument could be based on chemical properties, such as conductivity of the compound in the liquid state.

82. Ethyl alcohol can form intermolecular hydrogen bonds between its polar –OH groups, but dimethyl ether can not form hydrogen bonds.

83. **a.** two covalent bonds to both hydrogens; double bond between carbons H:C≡C:H
b. Fluorine and oxygen have only four electrons. :F:O:H
c. Halogens form one covalent bond, not three. :I:Cl:
d. Nitrogen forms three covalent bonds, not four. H:N::N:H

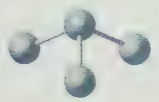


84. a. bent
b. tetrahedral
c. pyramidal

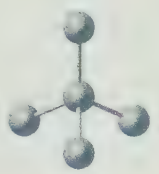
85. False. The bond dissociation energies exhibit no particular trend and, in fact, are fairly constant.

76. Give the angles between the orbitals of each hybrid.
a. sp^3 hybrids
b. sp^2 hybrids
c. sp hybrids

77. What is the geometry around the central atom in each of these simple molecules?



a.



b.

c.

d.

***78.** Which of the following molecules contains a central atom that does not obey the octet rule?
a. PBr_5
b. AlI_3
c. PF_3
d. $SiCl_4$

79. Vinegar contains the compound ethanoic acid, whose molecular formula is CH_3COOH.
a. Draw the electron dot structure of ethanoic acid. (*Hint:* The two carbon atoms are bonded to each other, and the two oxygens are bonded to the same carbon.)
b. Is the bonding between each of the oxygen atoms and the carbon the same?
c. Is the bonding between the carbon atom and each oxygen atom a polar or nonpolar bond?
d. Is ethanoic acid a polar molecule?

Think Critically

80. **Compare** Make a list of the elements in the compounds found in Table 8.2 on page 234. What do the elements that form covalent bonds have in common?

81. **Explain** Is there a clear difference between a very polar covalent bond and an ionic bond? Explain.

***82.** **Explain** Ethyl alcohol (CH_3CH_2OH) and dimethyl ether (CH_3OCH_3) each have the same molecular formula, C_2H_6O. Ethyl alcohol has a much higher boiling point (78°C) than dimethyl ether (–25°C). Propose an explanation for this difference.

83. **Evaluate** Although the relative positions of the atoms are correct in each of these molecules, there are one or more incorrect bonds in each of the electron dot structures. Identify the incorrect bonds. Draw the correct electron dot structure for each molecule.
a. H═C═C═H
b. :F—O—H
c. :I:::Cl:
d. H—N:::N—H

***84.** **Predict** What shape do you expect for a molecule with a central atom and the following pairings?
a. two bonding pairs of electrons and two nonbonding pairs of electrons
b. four bonding pairs and zero nonbonding pairs
c. three bonding pairs and one nonbonding pair

85. **Interpret Tables** Is this statement true or false? "As the electronegativity difference between covalently bonded atoms increases, the strength of the bond increases." Use the table below to justify your answer.

Bond	Electronegativity difference	Bond dissociation energy (kJ/mol)
C—C	2.5 – 2.5 = 0.0	347
C—H	2.5 – 2.1 = 0.4	393
C—N	3.0 – 2.5 = 0.5	305
C—O	3.5 – 2.5 = 1.0	356

Enrichment

86. **Explain** There are some compounds in which one atom has more electrons than the corresponding noble gas. Examples are PCl_5, SF_6, and IF_7. Draw the electron dot structures of P, S, and I atoms and of these compounds. Considering the outer shell configuration of P, S, and I, develop an orbital hybridization scheme to explain the existence of these compounds.

87. **Use Models** Draw the electron dot structure of formic acid, H_2CO_2. The carbon is the central atom, and all the atoms are attached to the carbon except for a hydrogen bonded to an oxygen.

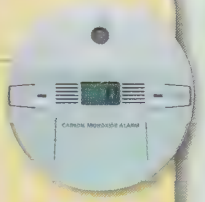
88. **Predict** The electron structure and geometry of the methane molecule (CH_4) can be described by a variety of models, including electron dot structure, simple overlap of atomic orbitals, and orbital hybridization of carbon. Draw the electron dot structure of CH_4. Sketch two molecular orbital pictures of the CH_4 molecule. For your first sketch, assume that one of the paired $2s^2$ electrons of carbon has been promoted to the empty $2p$ orbital. Overlap each half-filled atomic orbital of carbon to a half-filled $2s$ orbital of hydrogen. What is the predicted geometry of the CH_4 molecule, using this simple overlap method? In your second sketch, assume hybridization of the $2s$ and $2p$ orbitals of carbon. Now what geometry would you predict for CH_4? Which picture is preferable based on the facts that all H—C—H bond angles in CH_4 are 109.5° and all C—H bond distances are identical?

89. **Use Models** Oxalic acid, $C_2H_2O_4$, is used in polishes and rust removers. Draw the electron dot structure for oxalic acid given that the two carbons are bonded together but neither of the hydrogen atoms is bonded to a carbon atom.

90. **Use Models** Draw as many resonance structures as you can for HN_3. (*Hint:* The three nitrogen atoms are bonded in a row, and the hydrogen atom is bonded to a nitrogen atom at the end of the row of nitrogens.)

***91.** **Explain** Draw an electron dot structure for each molecule and explain why it fails to obey the octet rule.

a. BeF_2 **c.** ClO_2 **e.** XeF_2
b. SiF_6 **d.** BF_3



Write About Science

92. **Explain** Describe what a molecular compound is. Explain how a molecular formula is the chemical formula of a molecular compound.

93. **Research a Problem** Research how chemists know that an oxygen molecule has unpaired electrons. Write a brief report on what you find.

CHEMYSTERY

What's That Alarm?

The family realized that the alarm was caused by carbon monoxide (CO). In carbon monoxide, the carbon and oxygen atom are joined by a triple covalent bond. Although carbon monoxide and carbon dioxide are both made of carbon and oxygen atoms, they have very different properties.

Carbon monoxide is an odorless, tasteless gas. When it gets into the bloodstream, it causes the hemoglobin to convert to a form that is unable to transport oxygen. Symptoms of carbon monoxide poisoning include headaches, nausea, vomiting, and mental confusion. Exposure to high levels of carbon monoxide can result in death.

Fuel-burning appliances, such as water heaters, fireplaces, furnaces, and gas stoves, produce carbon monoxide. If the appliance is not functioning properly, it may release unsafe amounts of carbon monoxide. If a home contains one of these appliances, then the homeowners should install carbon monoxide detectors, since the gas cannot be detected by sight or smell.

94. **Use Models** Draw the electron dot structures of carbon monoxide and carbon dioxide. Describe the structural differences between these two molecules.

95. Connect to the **BIG**IDEA How does covalent bonding allow there to be different molecular compounds composed of the same kinds of atoms?

ASSESSMENT

CHEMYSTERY

APPLY CONCEPTS Explain that carbon and oxygen can combine to form two gases, carbon dioxide and carbon monoxide, depending on whether or not combustion of carbon is complete, or incomplete. Incomplete combustion occurs when there is a limited supply of air and only half as much oxygen adds to the carbon. Remind students that CO and CO_2 contain the same elements, but they have different properties because of their molecular structure. As a class, discuss the factors that affect the molecular properties of these two gases. Explain that the effects of CO on human health are due to the structure of CO and how it interacts with hemoglobin molecules in red blood cells.

CHEMYSTERY ANSWERS

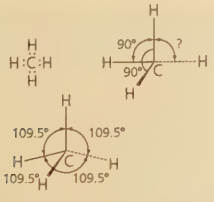
94. :C⁝⁝O: :Ö⁝⁝C⁝⁝Ö: Carbon monoxide is one carbon and one oxygen atom joined by a triple bond. Carbon dioxide is one carbon atom joined to two oxygen atoms by double bonds.

95. **BIG**IDEA Atoms joined by covalent compounds can make compounds consisting of the same atoms, but with different numbers of each atom. The type of covalent bond (single, double, or triple) may be different depending on how many atoms are sharing electrons with each other.

Answers

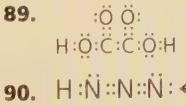
ENRICHMENT

86.



P forms 5 hybrid orbitals (dsp^3), *S* forms 6 hybrid orbitals (d^2sp^3), and I forms 7 hybrid orbitals (d^3sp^3).

87.



88.

The first sketch shows carbon's three p orbitals oriented at 90° angles, resulting in a pyramidal structure for the carbon atom with three hydrogen atoms. The 4th C-H bond, formed with carbon's 2s orbital and a hydrogen atom's 1s orbital, is at unspecified angles to the other three C-H bonds. The second sketch is tetrahedral. The bond angles in the first sketch are not all the same; some are 90°. The bond angles in the second sketch are all 109.5° The second sketch is correct. (Note: The wedge-shaped lines come out of the page; the dotted lines recede into the page.)

89.

90. H:N̈::N::N̈: ⟷ H:N̈:N::N:

91. **a.** Be has only 4 valence electrons. :F̈–Be–F̈:

b. S has 12 valence electrons.

c. Cl has only 7 valence electrons.

d. B has only 6 valence electrons.

e. Xe has 10 valence electrons. :F̈–Ẍe–F̈:

WRITE ABOUT SCIENCE

92. Students should write that a molecular compound is a compound composed of molecules. A molecular formula shows how many atoms of each element a molecule contains.

93. Oxygen is paramagnetic, which means that it tends to be attracted to a magnetic field. This behavior is characteristic of substances that have unpaired electrons. Therefore, oxygen must have unpaired electrons.

b. $1s^2 2s^2 2p^6$
c. $1s^2 2s^2 2p^6$
d. $1s^2 2s^2 2p^6 3s^2 3p^6$

115. No, an alloy is a homogeneous mixture.

Cumulative Review

96. Name three indicators of chemical change.

***97.** Make the following conversions:
a. 66.5 mm to micrometers
b. 4×10^{-2} g to centigrams
c. 5.62 mg/mL to decigrams per liter
d. 85 km/h to meters per second

98. How many significant figures are in each measurement?
a. 0.00052 m **c.** 5.050 mg
b. 9.8×10^4 g **d.** 8.700 mL

99. How many neutrons are in each atom?
a. silicon-30 **c.** nitrogen-15
b. magnesium-24 **d.** chromium-50

100. How do isotopes of an atom differ?

***101.** In a neutral atom, the number of which two subatomic particles must always be equal?

102. How many electrons are in the 2*p* sublevel of an atom of each element?
a. aluminum **c.** fluorine
b. carbon **d.** lithium

103. What happens to the wavelength of light as the frequency increases?

104. What does the 5 in $3d^5$ represent?

105. Write correct electron configurations for atoms of the following elements:
a. sodium **c.** phosphorus
b. sulfur **d.** nitrogen

106. How does the ionic radius of a typical anion compare with the radius for the corresponding neutral atom?

107. What criteria did Mendeleev and Moseley use to arrange the elements on the periodic table?

108. Give the electron configuration of the element found at each location in the periodic table.
a. Group 1A, period 4
b. Group 3A, period 3
c. Group 6A, period 3
d. Group 2A, period 6

***109.** Identify the larger atom of each pair.
a. calcium and barium
b. silicon and sulfur
c. sodium and nitrogen

110. Which of these statements about the periodic table is correct?
I. Elements are arranged in order of increasing atomic mass.
II. A period is a horizontal row.
III. Nonmetals are located on the right side of the table.
a. I only
b. I and II only
c. I, II, and III
d. I and III only
e. II and III only

***111.** Which of the following ions has the same number of electrons as a noble gas?
a. Al^{3+}
b. O^{2-}
c. Br^-
d. N^{3-}

112. Which element is likely to form an ionic compound with chlorine?
a. iodine
b. cesium
c. helium

113. How many valence electrons does each atom have?
a. argon
b. aluminum
c. selenium
d. beryllium

114. Write the electron configuration of each ion.
a. oxide ion
b. magnesium ion
c. nitride ion
d. potassium ion

115. An alloy is composed of two or more elements. Is an alloy a compound? Explain your answer.

Standardized Test Prep for Indiana

Standards: C.3.1, C.3.2, C.3.4

Select the choice that best answers each question or completes each statement.

1. A bond in which two atoms share a pair of electrons is not
   (A) a coordinate covalent bond.
   (B) a polar covalent bond.
   (C) an ionic bond.
   (D) a nonpolar covalent bond.

2. How many valence electrons are in a molecule of phosphoric acid, H_3PO_4?
   (A) 7 **(C)** 24
   (B) 16 **(D)** 32

3. Which of these molecules can form a hydrogen bond with a water molecule?
   (A) N_2 **(C)** O_2
   (B) NH_3 **(D)** CH_4

4. Which substance contains both covalent and ionic bonds?
   (A) NH_4NO_3 **(C)** LiF
   (B) CH_3OCH_3 **(D)** $CaCl_2$

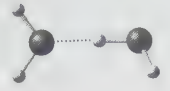
5. Which of these bonds is most polar?
   (A) H—Cl **(C)** H—F
   (B) H—Br **(D)** H—I

Use the description and data table below to answer Questions 6–9.

The table relates molecular shape to the number of bonding and nonbonding electron pairs in molecules.

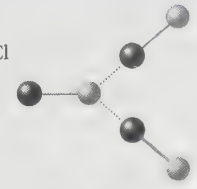
Bonding pairs	Non-bonding pairs	Arrangement of electron pairs	Molecular shape	Example
4	0	tetrahedral	tetrahedral	CH_4
3	1	tetrahedral	pyramidal	NCl_3
2	2	tetrahedral	bent	H_2S
1	3	tetrahedral	linear	HF

6. Draw the electron dot structure for each example molecule.



7. Explain why the arrangement of electron pairs is tetrahedral in each molecule.

8. H_2S has two hydrogen atoms bonded to a sulfur atom. Why isn't the molecule linear?



9. What is the arrangement of electron pairs in PBr_3? Predict the molecular shape of a PBr_3 molecule.

For Questions 10–11, identify the type of intermolecular bonding represented by the dotted lines in the drawings.

10. H_2O

11. BrCl

Tips for Success

Connectors Sometimes two phrases in a true/false question are connected by a word such as *because*. The word implies that one thing caused another thing to happen. Statements that include such words can be false even if both parts of the statement are true by themselves.

In Questions 12–14, a statement is followed by an explanation. Decide if each statement is true, and then decide if the explanation given is correct.

12. A carbon monoxide molecule has a triple covalent bond because carbon and oxygen atoms have an unequal number of valence electrons.

13. Xenon has a lower boiling point than neon because dispersion forces between xenon atoms are stronger than those between neon atoms.

14. The nitrate ion has three resonance structures because the nitrate ion has three single bonds.

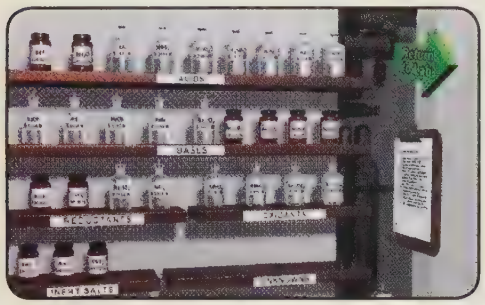
Online Teacher's Edition
Naming Ionic Compounds



What's Online

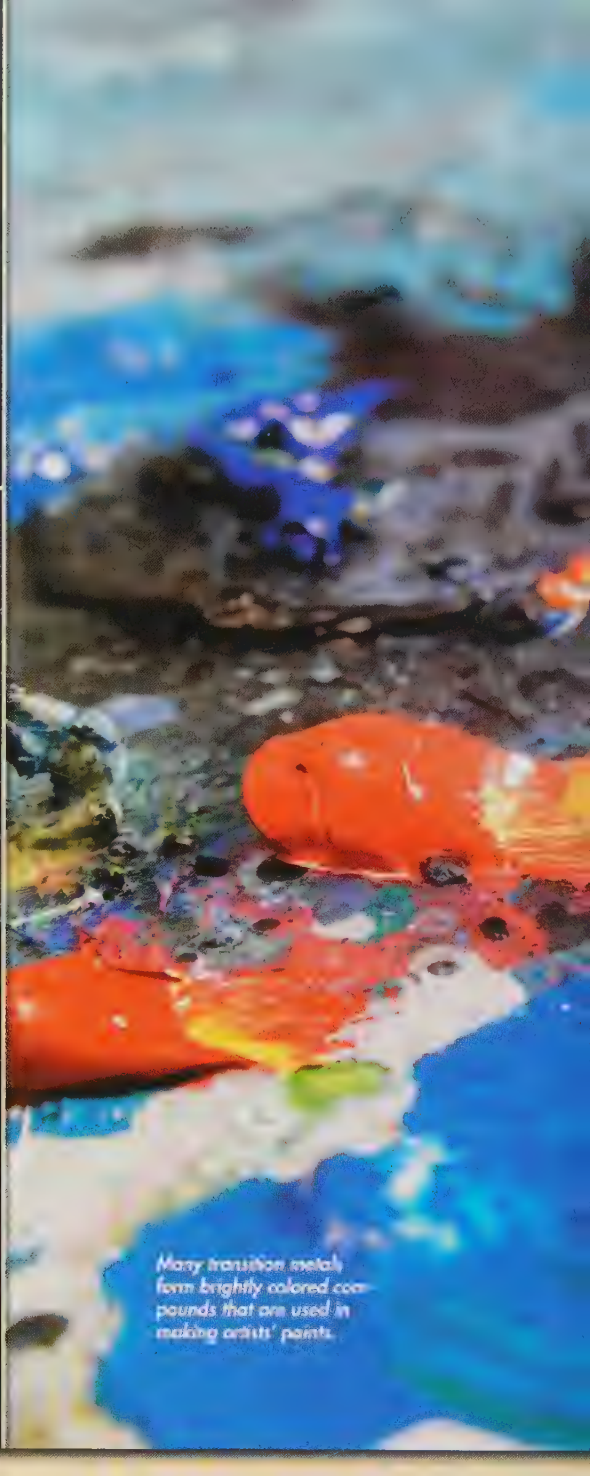
CHEM TUTOR Students access guided, step-by-step tutorials for naming and writing formulas for compounds and for calculating mass ratios.

PROBLEM-SOLVING HELP Students can practice key problem-solving skills in an online problem set.

MATH HELP Identify the students who struggle with math by assigning an online math skills diagnostic test. These students can then improve and practice math skills using the MathXL tutorial system.

VIRTUAL LAB Students go on an animated virtual lab tour in which ionic compounds are explored in a simulated laboratory environment.

KINETIC ART Students watch animations of selected figures from the chapter and answer questions that check for understanding.



CONCEPTS IN ACTION Students watch an overview of a key chapter concept using real-world contexts and concrete examples and analogies. Each activity includes an interactive animation followed by analysis questions.

IN ACADEMIC STANDARDS for SCIENCE

Nature of Science

- Clearly communicate their ideas and results of investigations verbally and in written form using tables, graphs, diagrams, and photographs.
- Use analogies and models (mathematical and physical) to simplify and represent systems that are difficult to understand or directly experience due to their size, time scale, or complexity, and recognize the limitations of analogies and models.

Standard 3: Bonding and Molecular Structure

C.3.4 Draw structural formulas for and name simple molecules.

C.3.5 Predict chemical formulas for ionic compounds given their name and vice versa.

Focus on ELL

1 CONTENT AND LANGUAGE Write the the chapter title on the board, and underline the words *Names* and *Formulas*. Ask students to predict the difference between a chemical name and a chemical formula.

BEGINNING: LOW/HIGH Rewrite the lesson titles containing a conjugate as two sentences. Read the new lesson titles aloud.

INTERMEDIATE

LOW Present previously learned examples of names and formulas of simple compounds.

HIGH Predict how naming compounds differs from writing formulas for compounds.

ADVANCED: LOW/HIGH Use information from previous chapters to predict what is likely to vary between naming ions, ionic compounds, and molecular compounds. Begin a list of naming rules for each.

BIG IDEAS

- **ELECTRONS AND THE STRUCTURE OF ATOMS**
- **BONDING AND INTERACTIONS**

Essential Questions:

1. *How does the periodic table help you determine the names and formulas of ions and compounds?*
2. *What is the difference between an ionic and a molecular compound?*

CHEMYSTERY

Cucumber Blunder

Tara's friend, Ellie, raves about the delicious lime pickles that Tara's grandma makes. As a surprise, Tara decided to make a batch for Ellie. She got the recipe from her grandma. It called for "1 cup of lime for every 3 pounds of cucumbers."

When the pickles were ready, Tara proudly presented the gift to Ellie. She watched Ellie's face as she bit into a pickle. After the first bite, Ellie made an awful face. "What's wrong?" Tara asked. After a short pause, Ellie replied, "They taste . . . funny." Tara tried one and agreed; they tasted nothing like her grandma's pickles. What did Tara do wrong?

▶ Connect to the BIG IDEA As you read about naming compounds, think about what might have caused Tara's cucumber blunder.

INDIANA'S ACADEMIC STANDARDS FOR SCIENCE

Bonding and Molecular Structure C.3.4, C.3.5. See lessons for details.

Introduce the Chapter

REAL-WORLD CONNECTION Use this activity to draw attention to information students can obtain by looking at the chemical names of ingredients in a variety of household products.

Activity *Display a selection of household products or just their packaging labels. Examples include soap, detergent, toothpaste, shampoo, ibuprofen, bathroom cleaner, windshield wiper fluid, sunscreen, and food. Make sure that at least one chemical name is displayed on the label and that it indicates the elements in the compound.* Have students work with a partner to examine the ingredients listed on each package and record the chemical names with elements they recognize. **Ask** What can you learn from the chemical names? *(the elements in the compounds)* **Ask** Would knowing the chemical formula of an ingredient help you to know more, less, or about the same amount of information? Explain. *(More; the formula would show the proportion of the elements and possibly the type of bonding.)*

UbD

Understanding by Design

Students are building toward naming and writing formulas for compounds using their knowledge of atoms, ions, and bonding.

PERFORMANCE GOALS At the end of Chapter 9, students will be able to answer the essential questions by applying their knowledge of ions, ionic compounds, and molecular compounds. Students will also be able to name and write formulas for compounds.

ESSENTIAL QUESTIONS Read the essential questions aloud. **Ask** What is an ion? *(an atom or group of atoms that has a positive or negative charge)* **Ask** How is an ion different from a molecule? *(An ion has a charge, but a molecule is neutral.)*

BIG IDEA Use the photo of an artist's paints to help students connect to the concepts they will learn in this chapter. Have students study the photograph. Have students imagine that the artist holding the brush needs to buy a new tube of green paint to finish a picture, but his supplier is out of his favorite brand, and none of the other manufacturers use the same common name for that particular hue. **Ask** How could the artist make sure he gets an exact match? *(Answers will vary.)* Explain that all paint pigments have official color index name codes, such as PG7, which stands for Pigment Green 7. The artist can use the color index name code to make sure he buys an exact match.

Next, have students read the caption. **Ask** What is unique about transition elements? *(Many transition elements form more than one ion.)* Point out that early chemists faced the same challenges identifying chemical compounds with these elements as paint manufacturers do naming paint colors. Explain that, in this chapter, students will discover how chemists make sure that each chemical compound is identified by a unique name and formula.

CHEMYSTERY Have students read over the CHEMystery. Connect the CHEMystery to the Big Ideas of Electrons and the Structure of Atoms and Bonding and Interactions by having students describe what information they get by reading the chemical formula or chemical name of a compound. For example, write "water" and "H_2O" on the board, and point out that the formula gives information about the composition of water that the term "water" does not supply. Ask students to predict why the lime pickles Tara made tasted funny. As a hint, write "lime" on the board, and ask students how much information they can get from just the name.

LESSON 9.1

Key Objectives

9.1.1 EXPLAIN how to determine the charges of monatomic ions.

9.1.2 EXPLAIN how polyatomic ions differ from and are similar to monatomic ions.

Additional Resources

Reading and Study Workbook, Lesson 9.1

Available online or DVD-ROM:

- Lesson 9.1 Review
- Interpreting Graphics

PearsonChem.com

Engage

CHEMISTRY & YOU Note that it is difficult to converse with people in a different country unless you are familiar with their language. Emphasize that chemists everywhere use the same chemical language. **Ask** Why is it important that there be only one language of chemistry? *(Chemists need to communicate with one another and having the same names for a compound makes this easier.)*

Activate Prior Knowledge

Have students review the meanings of the terms *anion*, *cation*, and *ion*. Have students locate their working copy of the periodic table and practice determining the charge on elements in the different groups.

IN ACADEMIC STANDARDS for SCIENCE

- Use analogies and models (mathematical and physical) to simplify and represent systems that are difficult to understand or directly experience due to their size, time scale, or complexity, and recognize the limitations of analogies and models.

C.3.5 Write chemical formulas for ionic compounds given their name and vice versa.

9.1 Naming Ions

C.3.5 Write chemical formulas

CHEMISTRY & YOU

Q: *Do you speak "Chemistry"?* Try looking at the ingredient label on a household product—a bottle of shampoo, a tube of toothpaste, a box of detergent. Do the names of the ingredients make sense? To truly understand chemistry, you must learn its language. Part of learning the language of chemistry involves understanding how to name ionic compounds. For this you need to know how to name ions.

Key Questions

How can you determine the charges of monatomic ions?

How do polyatomic ions differ from monatomic ions? How are they similar?

Vocabulary

- monatomic ion

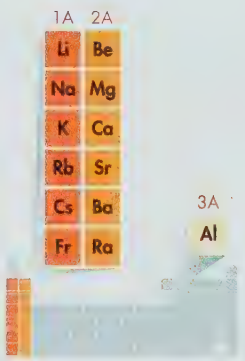

Figure 9.1
Elements That Form Cations
These representative elements form positive ions with charges equal to their group number.

Monatomic Ions

How can you determine the charges of monatomic ions?

Ionic compounds consist of a positive metal ion and a negative nonmetal ion combined in a proportion such that their charges add up to a net charge of zero. For example, the ionic compound sodium chloride (NaCl) consists of one sodium ion (Na^+) and one chloride ion (Cl^-). Probably you are already familiar with the name and formula of sodium chloride, which is common table salt. But it is important, in learning the language of chemistry, to be able to name and write the chemical formulas for all ionic compounds. The first step is to learn about the ions that form ionic compounds. Some ions, called **monatomic ions,** consist of a single atom with a positive or negative charge resulting from the loss or gain of one or more valence electrons, respectively.

Cations Recall that metallic elements tend to lose valence electrons. Lithium, sodium, and potassium in Group 1A lose one electron to form cations. All the Group 1A ions have a 1+ charge (Li^+, Na^+, K^+, Rb^+, Cs^+, and Fr^+). Magnesium and calcium are Group 2A metals. They tend to lose two electrons to form cations with a 2+ charge (Mg^{2+} and Ca^{2+}), as do all the other Group 2A metals. Aluminum is the only common Group 3A metal. As you might expect, aluminum tends to lose three electrons to form a 3+ cation (Al^{3+}). **When the metals in Groups 1A, 2A, and 3A lose electrons, they form cations with positive charges equal to their group number.** Figure 9.1 shows some of the elements whose ionic charges can be obtained from their positions in the periodic table.

The names of the cations of the Group 1A, Group 2A, and Group 3A metals are the same as the name of the metal, followed by the word *ion* or *cation*. Thus Na^+ is the sodium ion (or cation), Ca^{2+} is the calcium ion (or cation), and Al^{3+} is the aluminum ion (or cation).

Focus on ELL

1 CONTENT AND LANGUAGE Begin the lesson by drawing students' attention to the word *monatomic* in the vocabulary list. Explain that the word *monatomic* has the prefix *mono-*, which means "single." Have students use this information to predict the meaning of the word *monatomic*.

2 FRONTLOAD THE LESSON Ask students if there is a particular naming system for babies in their home country, such as surname additions or endings. Relate this to the way chemists have a system to name ions.

3 COMPREHENSIBLE INPUT Have students practice think-aloud techniques as they investigate the tables and figures in this lesson. Demonstrate by asking specific questions, such as, *What is the charge on a cesium ion?* or *Which group contains cations with a +3 charge?* Allow students to respond with symbols, by pointing to the answer, or by using gestures to demonstrate their answer.

Table 9.1

Ion Symbols for Some Group A Elements

1A	2A	3A	4A	5A	6A	7A	8A
Li^+	Be^{2+}			N^{3-}	O^{2-}	F^-	
Na^+	Mg^{2+}	Al^{3+}		P^{3-}	S^{2-}	Cl^-	
K^+	Ca^{2+}			As^{3-}	Se^{2-}	Br^-	
Rb^+	Sr^{2+}					I^-	
Cs^+	Ba^{2+}						

Anions Nonmetals tend to gain electrons to form anions, so the charge of a nonmetallic ion is negative. **The charge of any ion of a Group A nonmetal is determined by subtracting 8 from the group number.** The elements in Group 7A form anions with a 1− charge (7 − 8 = −1). The name of an anion is not the same as the element's name. Anion names start with the stem of the element name and end in *-ide*. For example, two elements in Group 7A are fluorine and chlorine. The anions for these nonmetals are the fluor*ide* ion (F^-) and chlor*ide* ion (Cl^-). Anions of nonmetals in Group 6A have a 2− charge (6 − 8 = −2). Group 6A elements, oxygen and sulfur, form the ox*ide* anion (O^{2-}) and the sulf*ide* anion (S^{2-}), respectively. The first three elements in Group 5A, nitrogen, phosphorus, and arsenic, can form anions with a 3− charge (5 − 8 = −3). These anions have the symbols N^{3-}, P^{3-}, and As^{3-} and are called, respectively, nitr*ide* ion, phosph*ide* ion, and arsen*ide* ion. Figure 9.2 shows some common Group A elements that form anions. Table 9.1 summarizes the ionic charges of representative elements that can be obtained from the periodic table. The majority of the elements in the two remaining representative groups, 4A and 8A, usually do not form ions.

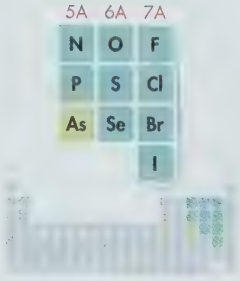

Figure 9.2 Elements That Form Anions
These representative elements form negative ions with charges equal to 8 minus the group number of the element.

Metals That Form More Than One Ion The metals of Groups 1A, 2A, and 3A consistently form cations with charges of 1+, 2+, and 3+, respectively. Many of the transition metals (Groups 1B–8B) form more than one cation with different ionic charges. Some of these are shown in Figure 9.3. **The charges of the cations of many transition metal ions must be determined from the number of electrons lost.** For example, the transition metal iron forms two common cations, Fe^{2+} (two electrons lost) and Fe^{3+} (three electrons lost). Cations of tin and lead, the two metals in Group 4A, can also have more than one common ionic charge.

Two methods are used to name these ions. The preferred method is called the Stock system. In the Stock system, you place a Roman numeral in parentheses after the name of the element to indicate the numerical value of the charge. For example, the cation Fe^{2+} is named iron(II) ion. Note that no space is left between the element name and the Roman numeral in parentheses. The name for Fe^{2+} is read "iron two ion." The Fe^{3+} ion is named iron(III) ion and is read "iron three ion."

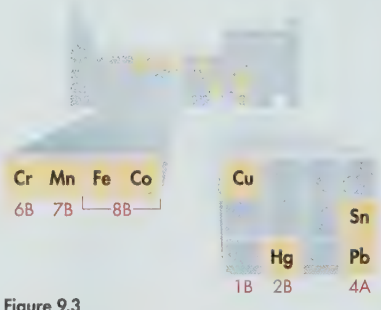

Figure 9.3
Elements That Form More Than One Ion
These metallic elements form more than one positive ion.
Identify ***Which of these elements are transition metals?***

Differentiated Instruction

ELL ENGLISH LANGUAGE LEARNERS Have students prepare flash cards with the name of a monatomic or polyatomic ion on one side and its formula on the other side. Pair students so they can use the flash cards to quiz each other.

L1 SPECIAL NEEDS STUDENTS For some students, the charge that results when electrons are transferred is counterintuitive—additions result in a negative charge, subtractions result in a positive charge. Give students different-colored disks to represent protons and electrons in neutral atoms. Remove or add electrons and ask students to find the charge of the resulting "ion."

L3 ADVANCED STUDENTS Ask students to determine the resulting compound that forms between a metal ion and a polyatomic ion, and what type of bonds are involved. *(Ionic compound; the resulting compound contains both ionic bonds and covalent bonds.)* Ask students to determine the type of bonds used to hold atoms together in all polyatomic ions. *(covalent bonds)*

Foundations for Reading

BUILD VOCABULARY As a class, create a list of words that begin with the prefixes *mono-* and *poly-*. *(Students may respond with words such as* monotone, monochrome, monopoly, polynomial, *or* polygon.*)* Discuss the meanings of each word. **Ask** How do you think monatomic ions and polyatomic ions differ? *(A monatomic ion has one atom; a polyatomic ion has more than one atom.)*

READING STRATEGY Prior to reading the lesson, have students create a chart to compare information about charge, composition, and name endings of various ions.

Explain

Monatomic Ions

USE VISUALS Have students study Figures 9.1 and 9.2. Have students note that in each figure, the periodic table is shown in the background to help them locate the groups being discussed. **Ask** How do the ions formed by metals in Groups 1A, 2A, and 3A differ from the ions formed by nonmetals in Groups 5A, 6A, and 7A? *(Groups 1A, 2A, and 3A form positive ions; Groups 5A, 6A, and 7A form negative ions.)* **Ask** Are the ions formed by the transition metals cations or anions? *(They are cations.)*

Explore

Class Activity

PURPOSE Students will use the periodic table for writing symbols for monatomic ions.

MATERIALS blank photocopy of the periodic table for each pair of students

PROCEDURE Have students work in pairs. Allow them to refer to their textbooks or other resource materials. In the element blocks on the blank periodic table, have them write the symbols and names of the cations and anions of as many elements as possible. Have them use their tables to identify any trends in ionic charges. Encourage them to keep their tables for reference.

Answers

FIGURE 9.3 Cr, Mn, Fe, Co, Cu, and Hg are transition metals; Sn and Pb are not.

Explain

CHEMISTRY & YOU The periodic table is a very useful tool for naming ions. Cations from Groups 1A–3A are named by stating the element name followed by the word *ion* or *cation*. Anions from Groups 5A–7A are named by adding the suffix *-ide* to the element stem.

Explore

TeacherDemo

PURPOSE Students will see the various colors of solutions of transition metal ions and practice naming the ions.

MATERIALS beakers containing solutions of soluble metal salts, for example: $MnCl_2$, $FeCl_2$, $CoCl_2$, $NiCl_2$, and $CuCl_2$, or ions such as Co^{3+}, Cr^{3-}, Fe^{3+}, Ni^{2+}, and Mn^{2+}

PROCEDURE Write the symbols for the metal ions on the board. Have students describe the colors of the solutions. Ask them to use Table 9.2 to write the Stock and classical names of each cation. Ask students to suggest why chemists prefer to use the Stock system for naming ions.

Extend

Divide students into research teams to gather data about paint pigments from different sources. Assign each group one of the following tasks:

- Examine the pigments available at an art-supply store. Obtain as much information as possible from their labels and then use the Internet to research their composition.
- Create a series of questions and conduct an interview with at least two art teachers about their experience with pigments.
- Research the type of pigments available and popular during earlier eras; guide students to look for information about natural sources of pigments.
- Interview a curator or art restorer from a local museum to talk about using pigments to repair damaged art, authenticate art, or unmask a forgery.

CHEMISTRY & YOU

Q: *Suppose you were trying to teach someone how to name ions. Which rules about the "language of chemistry" would you emphasize?*

An older, less useful method for naming these cations uses a root word with different suffixes at the end of the word. The older, or classical, name of the element is used to form the root name for the element. For example, *ferrum* is Latin for iron, so *ferr-* is the root name for iron. The suffix *-ous* is used to name the cation with the lower of the two ionic charges. The suffix *-ic* is used with the higher of the two ionic charges. Using this system, Fe^{2+} is the ferrous ion, and Fe^{3+} is the ferric ion, as shown in Table 9.2. Notice that you can usually identify an element from what may be an unfamiliar classical name by looking for the element's symbol in the name. For example, *f*errous (Fe) is iron; *cu*prous (Cu) is copper; and *sta*nnous (Sn) is tin. A major disadvantage of using classical names for ions is that they do not tell you the actual charge of the ion. A classical name tells you only that the cation has either the smaller (*-ous*) or the larger (*-ic*) charge of the pair of possible ions for that element.

A few transition metals have only one ionic charge. The names of these cations do not have a Roman numeral. These exceptions include silver, with cations that have a 1+ charge (Ag^+), as well as cadmium and zinc, with cations that have a 2+ charge (Cd^{2+} and Zn^{2+}). As Figure 9.4 shows, some transition metal ions form colorful solutions.

Figure 9.4
Transition Metal Ions
Compounds of transition metals are often strongly colored. Solutions that contain transition metal ions can also be colored.

Table 9.2

Symbols and Names of Common Metal Ions With More Than One Ionic Charge

Symbol	Stock name	Classical name
Cu^+	Copper(I) ion	Cuprous ion
Cu^{2+}	Copper(II) ion	Cupric ion
Fe^{2+}	Iron(II) ion	Ferrous ion
Fe^{3+}	Iron(III) ion	Ferric ion
*Hg_2^{2+}	Mercury(I) ion	Mercurous ion
Hg^{2+}	Mercury(II) ion	Mercuric ion
Pb^{2+}	Lead(II) ion	Plumbous ion
Pb^{4+}	Lead(IV) ion	Plumbic ion
Sn^{2+}	Tin(II) ion	Stannous ion
Sn^{4+}	Tin(IV) ion	Stannic ion
Cr^{2+}	Chromium(II) ion	Chromous ion
Cr^{3+}	Chromium(III) ion	Chromic ion
Mn^{2+}	Manganese(II) ion	Manganous ion
Mn^{3+}	Manganese(III) ion	Manganic ion
Co^{2+}	Cobalt(II) ion	Cobaltous ion
Co^{3+}	Cobalt(III) ion	Cobaltic ion

*A diatomic elemental ion.

UbD

Check for Understanding

The Essential Question **How can you determine the charges of monoatomic ions?**

Assess students' comprehension by asking them to show you how they use the groups in the periodic table to determine the charge on any given monatomic ion. Students should properly use the terms *cations* and *anions* in their explanation.

ADJUST INSTRUCTION If students are having trouble answering, provide them a clean copy of the periodic table. Instruct them to use colored pencils to color code the groups within the table to help them determine the charges. Direct students to revisit the text following the *Cations* and *Anions* subheads.

Sample Problem 9.1

Naming Cations and Anions

Name the ion formed by each of the following elements:

a. potassium **b.** lead, 4 electrons lost **c.** sulfur

1 Analyze **Identify the relevant concepts.** You can use the periodic table to determine the charge of most Group A elements. Ions with positive charges are cations; ions with negative charges are anions. The names of nonmetallic anions end in *-ide*. Metallic cations take the name of the metal. Some metals, including transition metals, can form more than one cation. Use a Roman numeral in the Stock name or use the classical name with a suffix to name these metals.

2 Solve **Apply the concepts to this problem.**

	a. K	b. Pb	c. S
Write the symbol for the element.			
Determine the charge of the ion formed by the element.	1+	4+	2−
Determine whether the ion is a cation or an anion.	K^+ is a cation.	Pb^{4+} is a cation.	S^{2-} is an anion.
Apply the appropriate rules for naming the ion. Use a Roman numeral if necessary.	Following the rules for naming metallic cations, K^+ is named potassium ion.	Following the rules for naming metals that can form more than one cation, Pb^{4+} is named lead(IV) or plumbic ion.	Following the rules for naming nonmetallic anions, S^{2-} is named sulfide ion.

1. Name the ions formed by the following elements:
- **a.** selenium
- **b.** barium
- **c.** phosphorus
- **d.** iodine

2. How many electrons were lost or gained to form these ions?
- **a.** Fe^{3+} **c.** Cu^+
- **b.** O^{2-} **d.** Sr^{2+}

A negative charge means electrons gained; a positive charge means electrons lost.

Explain

Monatomic Ions

Sample Practice Problem

Write the symbol (including charge) for the ion formed by each element. Then classify each as an anion or a cation.

- **a.** arsenic (As^{3-}, *anion*)
- **b.** beryllium (Be^{2+}, *cation*)
- **c.** astatine (At^-, *anion*)
- **d.** gallium (Ga^{3+}, *cation*)

Professional Development Note

Two Kinds of Bonding

When an ionic compound forms between a metal ion and a polyatomic ion, the resulting compound contains both ionic bonds and covalent bonds. The atoms in all polyatomic ions are held together by covalent bonds.

Answers

1. **a.** selenide ion
   b. barium ion
   c. phosphide ion
   d. iodide ion
2. **a.** three electrons lost
   b. two electrons gained
   c. one electron lost
   d. two electrons lost

Explain

Polyatomic Ions

START A CONVERSATION Write the following formulas on the board: NaOH, H_2SO_4, NH_4NO_3, and Na_2CO_3. Ask students what these compounds have in common. *(Students may note that they all contain oxygen.)* Tell students that this is an important observation. Explain that all of these compounds contain ions that are made up of more than one type of atom. In ions such as these, oxygen is almost always present.

USE VISUALS. Direct students' attention to Table 9.3. Point out how the table is divided into sections according to charge: more than half of the ions have a charge of 1–, only two ions have charges of 3–, and both of these contain the phosphorus atom. Point out that the ammonium ion is the only common polyatomic ion with a 1+ charge, and it does not contain oxygen. The remaining ions have charges of 2–. Have students write the formulas on the board for all of the *-ate* and *-ite* pairs. **Ask** What do you notice about each of these pairs? *(They have the same charge.)* Emphasize that it is not the charge but rather the number of oxygen atoms in the members of an *-ate* and *-ite* pair that determines the endings of the names.

Explore

Class Activity

PURPOSE Students will visualize the geometry of some polyatomic ions.

MATERIALS foam balls and wooden sticks

PROCEDURE Pairs of students can research the three-dimensional structure of one of the polyatomic ions in Table 9.3. Have them prepare a ball-and-stick model of the ion. They may wish to differentiate atoms by size or color. Make sure that they pay attention to correct geometric placement of atoms.

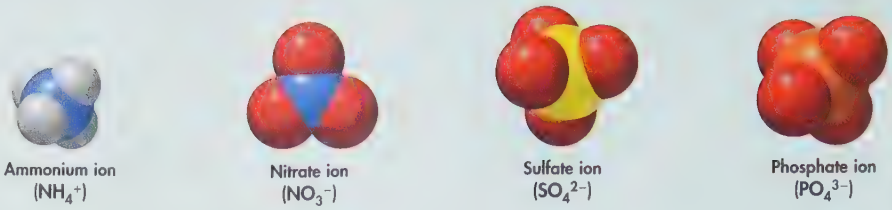

Figure 9.5 Polyatomic Ions
These molecular models show the arrangement of atoms in four common polyatomic ions.
Compare *How does the ammonium ion differ from the other three ions?*

Table 9.3
Common Polyatomic Ions

Charge	Formula	Name
1–	$H_2PO_4^-$	Dihydrogen phosphate
	$C_2H_3O_2^-$	Ethanoate
	HSO_3^-	Hydrogen sulfite
	HSO_4^-	Hydrogen sulfate
	HCO_3^-	Hydrogen carbonate
	NO_2^-	Nitrite
	NO_3^-	Nitrate
	CN^-	Cyanide
	OH^-	Hydroxide
	MnO_4^-	Permanganate
	ClO^-	Hypochlorite
	ClO_2^-	Chlorite
	ClO_3^-	Chlorate
	ClO_4^-	Perchlorate
2–	HPO_4^{2-}	Hydrogen phosphate
	$C_2O_4^{2-}$	Oxalate
	SO_3^{2-}	Sulfite
	SO_4^{2-}	Sulfate
	CO_3^{2-}	Carbonate
	CrO_4^{2-}	Chromate
	$Cr_2O_7^{2-}$	Dichromate
	SiO_3^{2-}	Silicate
3–	PO_3^{3-}	Phosphite
	PO_4^{3-}	Phosphate
1+	NH_4^+	Ammonium

Polyatomic Ions

How do polyatomic ions differ from monatomic ions? How are they similar?

Some ions, such as the sulfate ion, are called polyatomic ions. **Unlike a monatomic ion, a polyatomic ion is composed of more than one atom. But like a monatomic ion, a polyatomic ion behaves as a unit and carries a charge.** The sulfate anion consists of one sulfur atom and four oxygen atoms. These five atoms together comprise a single anion with an overall 2– charge. The formula is written SO_4^{2-}. You can see the structure of the sulfate ion along with three other common polyatomic ions in Figure 9.5.

The names and formulas of some common polyatomic ions are shown in Table 9.3, grouped according to their charges. Note that the names of most polyatomic anions end in *-ite* or *-ate*. For example, notice the endings of the names of the hypochlor*ite* ion (ClO^-) and the hydrogen carbon*ate* ion (HCO_3^-). Also notice that three important ions have different endings—the cyan*ide* anion (CN^-), the hydrox*ide* anion (OH^-), and the ammon*ium* cation (NH_4^+).

Sometimes the same two or three elements combine in different ratios to form different polyatomic ions. Several examples appear in Table 9.3. Look for pairs of ions for which there is both an *-ite* and an *-ate* ending, for example, sulfite and sulfate. Examine the charge on each ion in the pair. Note the number of oxygen atoms and the endings on each name. You should be able to discern a pattern in the naming convention.

-ite	*-ate*
SO_3^{2-}, sulfite	SO_4^{2-}, sulfate
NO_2^-, nitrite	NO_3^-, nitrate
ClO_2^-, chlorite	ClO_3^-, chlorate

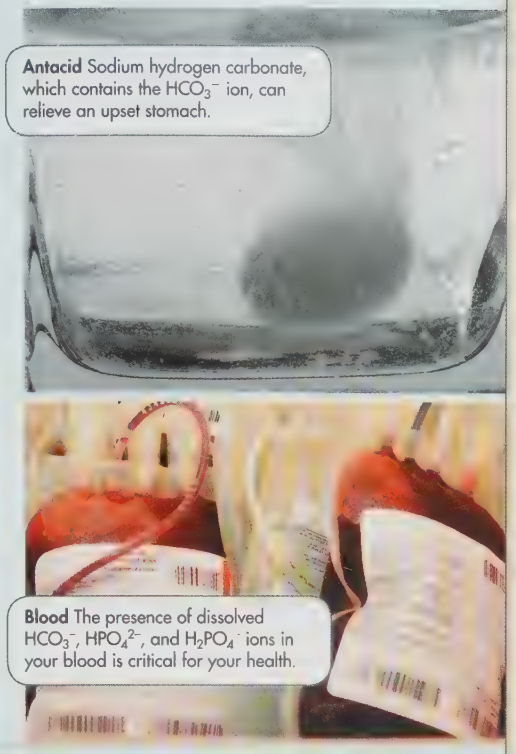
UbD **Check for Understanding**

BIGIDEA ELECTRONS AND THE STRUCTURE OF ATOMS Assess students' comprehension of the Big Idea by writing on the board the names and formulas of at least ten different polyatomic ions. Purposely mismatch the names so that they do not appear with the correct formulas. Challenge students to see how quickly they can rearrange the names and formulas so that they are paired correctly.

ADJUST INSTRUCTION If students are having trouble answering, have them review Table 9.3 and the supporting text. Then ask them to identify and correct the incorrect pairings.

The charge on each polyatomic ion in a given pair is the same. The *-ite* ending indicates one less oxygen atom than the *-ate* ending. However, the ending does not tell you the actual number of oxygen atoms in the ion. For example, the nitrite ion has two oxygen atoms, and the sulfite ion has three oxygen atoms. All anions with names ending in *-ite* or *-ate* contain oxygen.

When the formula for a polyatomic ion begins with H (hydrogen), you can think of the H as representing a hydrogen ion (H^+) combined with another polyatomic ion. For example, HCO_3^- is a combination of H^+ and CO_3^{2-}. Note that the charge on the new ion is the algebraic sum of the ionic charges of the two component ions.



$$H^+ + CO_3^{2-} \longrightarrow HCO_3^-$$
carbonate → hydrogen carbonate

$$H^+ + PO_4^{3-} \longrightarrow HPO_4^{2-}$$
phosphate → hydrogen phosphate

$$H^+ + HPO_4^{2-} \longrightarrow H_2PO_4^-$$
hydrogen phosphate → dihydrogen phosphate

The hydrogen carbonate anion (HCO_3^-), the hydrogen phosphate anion (HPO_4^{2-}), and the dihydrogen phosphate anion ($H_2PO_4^-$) are essential components of living systems. In contrast, the cyanide ion (CN^-) is extremely poisonous to living systems because it blocks a cell's means of producing energy. Figure 9.6 shows two uses for compounds with hydrogen-containing polyatomic ions.

Figure 9.6 Hydrogen-Containing Polyatomic Ions Polyatomic ions that contain hydrogen are part of several compounds that affect your daily life.

Antacid Sodium hydrogen carbonate, which contains the HCO_3^- ion, can relieve an upset stomach.

Blood The presence of dissolved HCO_3^-, HPO_4^{2-}, and $H_2PO_4^-$ ions in your blood is critical for your health.

9.1 LessonCheck

3. Explain How can you determine the charges of metal cations? Of nonmetal anions? Of transition metal cations?

4. Review What are the similarities and differences between polyatomic ions and monatomic ions?

5. Identify What are the charges on ions of Group 1A, Group 3A (aluminum), and Group 5A?

6. Describe Write the symbol for the ion of each element. Classify the ion as an anion or a cation, and name the ion.

a. potassium
b. oxygen
c. bromine
d. tin (2 electrons lost)
e. beryllium
f. cobalt (3 electrons lost)

7. Describe Write the symbol or formula (including charge) for each of the following ions:

a. ammonium ion
b. chromium(II) ion
c. chromate ion
d. nitrate ion

8. Compare How do the differences in the polyatomic ions PO_3^{3-} and PO_4^{3-} help you determine whether each ends in *-ite* or *-ate*?

BIG IDEA
ELECTRONS AND THE STRUCTURE OF ATOMS

9. How does the electron configuration of an ion of a Group 1A or Group 7A element compare to that of the nearest noble gas?

Lesson Check Answers

3. Metals in Groups 1A, 2A, and 3A form cations with charges equal to their group numbers. Group A nonmetals form anions with charges equal to 8 minus their group numbers. Often, the charge of a transition metal cation must be determined from the number of electrons lost.

4. Both carry a charge. A polyatomic ion is composed of more than one atom; a monatomic ion is a single atom.

5. Group 1A metals, 1+; Group 3A (aluminum), 3+; Group 5A nonmetals, 3−

6.
a. K^+, cation, potassium ion
b. O^{2-}, anion, oxide ion
c. Br^-, anion, bromide ion
d. Sn^{2+}, cation, tin(II) ion
e. Be^{2+}, cation, beryllium ion
f. Co^{3+}, cation, cobalt(III) ion

7. **a.** NH_4^+ **b.** Cr^{2+} **c.** CrO_4^{2-} **d.** NO_3^-

8. One has one more oxygen atom than the other. The one with more oxygen atoms (PO_4^{3-}) gets the *-ate* ending, while the other (PO_3^{3-}) gets the *-ite* ending.

Extend

Connect to MEDICINE

Explain to students that there exists a stockpile of potassium for human use in the event of a nuclear accident that results in fallout of radioactive iodine-131. Convey that whether the iodine is radioactive or not, absorbed iodine accumulates in the thyroid gland. Have students find out what purpose potassium iodide would serve in this catastrophic event and why it is useful.

(If a dose of nonradioactive KI is ingested in a timely way after a nuclear accident, the iodide ion is taken up by the thyroid gland, decreasing the chances that the gland will take up iodine-131. Iodine-131 has a relatively short half-life of eight days, but it can cause thyroid cancer, especially in children.)

Evaluate

Informal Assessment

Write the following symbols on the board:

K, NH_3, CN, Mg, O, OH, Co, NH_4, Pb, PO_4, Ar, ClO, H_2O, and Zn. Have students write on an index card which symbol(s) on the board can exist as an ion by simply attaching a charge. *(K, CN, Mg, O, OH, Co, NH_4, Pb, PO_4, ClO, and Zn)* Ask students to identify the charges and name the corresponding ion. Then have students complete the 9.1 Lesson Check.

Reteach

Remind students that one of the most important properties of any compound is that it is electrically neutral. Use the periodic table and Tables 9.1, 9.2, and 9.3, and guide students through the reasoning process for naming and writing formulas of monatomic and polyatomic ions. Make sure students understand that since polyatomic ions carry a charge, they are always combined with other ions in compounds.

9. **BIG IDEA** The electron configurations for a cation from a Group 1A element and the preceding noble gas are the same. The electron configurations for an anion from a Group 7A element and the following noble gas are the same.

Answers

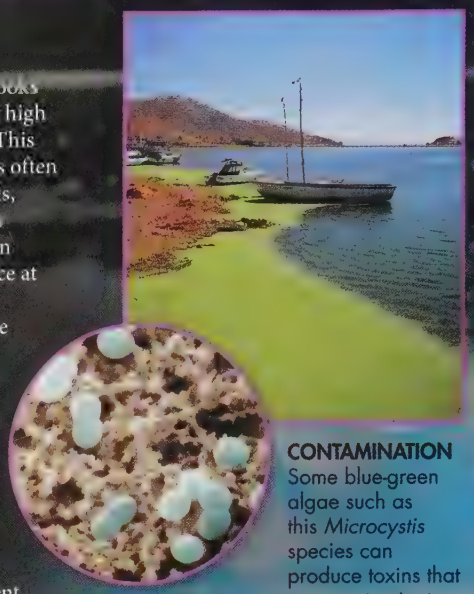
FIGURE 9.5 The ammonium ion is a cation and does not contain oxygen.

CHEMISTRY & YOU Have students examine the photograph in the background, and ask students to share any experiences they have had with algal blooms. Have them describe whether the algal bloom was near a factory, farmland, or a residential area. Encourage them to think about what the source of phosphates might have been for these algal blooms. Then pose the following question to students: *Consider what you know about algae growth and plant nutrient requirements. Based on this knowledge, how could you explain the response of algae to excess phosphates in their habitat?* You may need to assist students in the following ways:

- Phosphorus is a limiting factor in plant growth.
- High-phosphorus fertilizers are designed to boost plant reproduction by promoting flowering; these fertilizers are often referred to as "bloom boosters" when being marketed for landscaping use.
- Bacterial decay releases phosphate back into the water as part of the phosphorus cycle.

Explain

SUMMARIZE After students read the passage about algal blooms, lead them in a class discussion to summarize the main points and relate them to the chapter. **Ask** What causes freshwater algal blooms? *(excess phosphates in the water)* **Ask** What is the formula for a phosphate ion? *(PO_4^{3-})* **Ask** Are phosphates harmful or useful to algae? *(They are a necessary nutrient.)* **Ask** Why, then, are the phosphates a problem? *(They cause too much algae growth.)* Explain that algae have a short lifespan. After they die, the decay process includes a chemical reaction that uses oxygen. So much oxygen is used in this decay process that fish and other organisms do not have the oxygen they need to survive.



CRITICAL THINKING Have students consider why algal blooms are more common in ponds and lakes than in rivers. As a hint, have them look at characteristics of the lake in the photo. **Ask** What other conditions do you think make an algal bloom more likely to occur? *(warm water, plenty of sunshine, slowly flowing or stagnant water)*

Algal Blooms

Have you ever seen a lake or river covered with what looks like green or blue-green paint? This "paint" is actually high concentrations of algae that have reproduced rapidly. This event is called an algal bloom. Freshwater algal blooms often occur when there is an excess of phosphate compounds, commonly called phosphates, in the water. Phosphates are nutrients that algae need to survive. However, when phosphate levels are too high, algae grow and reproduce at unusually rapid rates.

Although most algal blooms are not harmful, some release toxins that are dangerous to humans and animals. Even nontoxic algal blooms may cause problems. For example, they may deplete the amount of oxygen in water and block sunlight, which underwater plants need to live. In addition, algal blooms may alter the taste and odor of the water.

Phosphates are found in fertilizers, detergents, and other cleaning products. These products can enter waterways by direct dumping and runoff. To help reduce the occurrence of algae blooms, government agencies and industries have collaborated to provide detergents, soaps, and cleaning agents that are more environmentally friendly. Next time you go to the store, notice that many detergents have a "Phosphate Free" label.

CONTAMINATION Some blue-green algae such as this *Microcystis* species can produce toxins that may contaminate drinking water.

Take It Further

1. **Identify** Sodium phosphate is one example of a phosphate compound. It was once widely used in detergents. Write the formula for this compound.
2. **Infer** How might an algal bloom affect aquatic grasses?
3. **Research a Problem** There are several other factors that can contribute to an algal bloom. Research this topic and identify at least two other factors that contribute to algal blooms.

SUFFOCATION Algal blooms can result in the death of fish by consuming too much dissolved oxygen in the water.

Differentiated Instruction

L1 STRUGGLING STUDENTS Have students identify three things in the photo that can happen when there is an excess of phosphate compounds in a freshwater pond. Make a list on the board as students describe them: excess algae in the water, toxins that can enter drinking water, low oxygen levels that can kill fish and other organisms.

LPR LESS PROFICIENT READERS After students read about algal blooms, have them create a T-chart on paper with the headings *Cause* and *Effect*. Then have them look back through the reading and list items that fit under each heading. If students have difficulty, you may wish to do this as a class project.

L1 ADVANCED STUDENTS Have students research the causes and effects of harmful algal blooms that occur in the ocean, creating so-called "dead zones." Students should also note any detection, prevention, or remediation actions that are being undertaken in response to these algal blooms, and discuss their relative effectiveness.

9.2 Naming and Writing Formulas for Ionic Compounds

C.3.5 Write chemical formulas

CHEMISTRY & YOU

Q: *What's the name of the secret ingredient?* If this ingredient isn't included in the recipe, the fruit can turn an ugly brown. Think about when you slice an apple at home. The slices don't look that tasty if you let them sit for too long because they begin to change color. But with the recipe and the secret ingredient, your apple slices could keep their color. Chemistry also uses recipes or formulas, but without any secrets. Once you know the rules, you can apply them and name any chemical compound. In this lesson, you will learn how to name ionic compounds.

Key Questions

How do you determine the formula and name of a binary ionic compound?

How do you determine the formula and name of a compound with a polyatomic ion?

Vocabulary

- binary compound

Binary Ionic Compounds

How do you determine the formula and name of a binary ionic compound?

In the days before the science of chemistry developed, the person who discovered a new compound often named it anything he or she wished. It was not uncommon for the name to describe some property of the substance or its source. For example, a common name for potassium carbonate (K_2CO_3) is *potash*. The name evolved because the compound was obtained by boiling wood ashes in iron pots. Baking soda ($NaHCO_3$) is another example. The common name, *baking soda*, describes its use in baking to make baked goods rise. Figure 9.7 shows a compound with the common name of cinnabar. Can you tell what elements are in cinnabar just from looking at the name? Unfortunately, such names do not tell you anything about the chemical composition of the compound.

The French chemist Antoine-Laurent Lavoisier (1743–1794) determined the composition of many compounds in his experiments to show how chemical compounds form. As more and more compounds were identified, Lavoisier recognized that it was becoming impossible to memorize all the unrelated names of the compounds. He worked with other chemists to develop a systematic method for naming chemical compounds. Their work is the basis for naming compounds today.

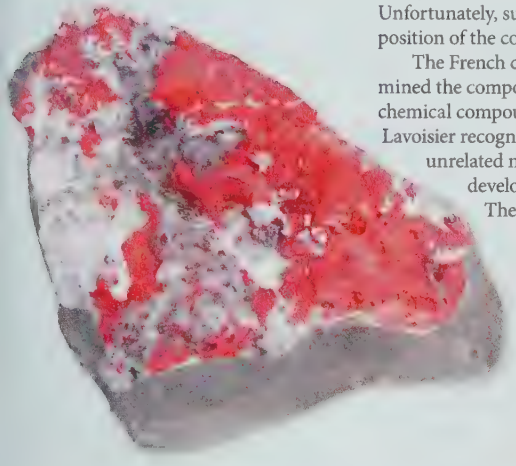


Figure 9.7 Cinnabar
The red substance that is deposited in this rock is commonly called cinnabar. Cinnabar (HgS) is comprised of mercury(II) ions and sulfide ions.

Focus on ELL

1 CONTENT AND LANGUAGE Write the key questions on the board. As a class, rewrite each question as two mini-questions and in words that are easy to understand. Provide a T-chart for students to record the rules for naming ionic compounds and examples of each.

2 FRONTLOAD THE LESSON Note that early clockmakers often used Roman numerals on their clocks, and display a clock face that uses Roman numerals instead of Arabic numerals (select one that uses "IV" rather than "IIII"). Explain that modern chemists also use Roman numerals, but for naming certain compounds rather than keeping time. Have students translate the clock numbers into their Arabic equivalents. If necessary, review with students how the Roman equivalents of 4, 6, 9, 11, and 12 are determined.

3 COMPREHENSIBLE INPUT Have pairs of students create a set of cards where half of the cards have the formula for ionic compounds and the other half has the names of the same ionic compounds. Each pair can then use the cards to play a game of memory, matching the name with the formula.

LESSON 9.2

Key Objectives

9.2.1 APPLY the rules for naming and writing formulas for binary ionic compounds.

9.2.2 APPLY the rules for naming and writing formulas for compounds with polyatomic ions.

Additional Resources

Reading and Study Workbook, Lesson 9.2

Available online or DVD-ROM:

- Lesson 9.2 Review
- Virtual Chem Lab, Lab 2

PearsonChem.com

Engage

CHEMISTRY & YOU Ask students to draw an analogy between a recipe that calls for four cups of sliced apples and one tablespoon of lemon juice and the formula for a chemical compound such as $CaCl_2$. *(Calcium and chlorine correspond to the ingredients sliced apples and lemon juice; the subscripts correspond to the quantities of the ingredients.)*

Build Background

Ask Do you or someone you know have a nickname? Does the nickname tell something about the person? *(Students will have a variety of responses.)* **Ask** Can you use a nickname alone to identify a person? *(no)* Point out that a compound's common name is similar to a nickname. It may be descriptive, but does not necessarily give enough information about the compound to positively determine its chemical composition.

IN ACADEMIC STANDARDS for SCIENCE

- Develop explanations based on reproducible data and observations gathered during laboratory investigations.

C.3.5 Write chemical formulas for ionic compounds given their name and vice versa.

Answers

1. Na_3PO_4
2. Algal blooms may prevent sunlight from reaching underwater plants. As a result, the plants could die.
3. increase in the water temperature, the amount of sunlight, or other nutrients such as nitrates

Foundations for Reading

BUILD VOCABULARY Explain that the word *compound* comes from the Latin *componere,* which means "to put." Tell students that parts are put together to make a whole; a compound always contains at least two parts. Explain that binary comes from the Latin word *bini* meaning "two-by-two" or "two-fold." Have students predict what a binary compound is. *(a compound with two parts)*

READING STRATEGY Have students preview the chapter. **Ask** What are the two types of compounds you will be learning about? *(binary ionic compounds and compounds with polyatomic ions)* **Ask** What do you think is the difference between a binary compound and a compound with a polyatomic ion? *(A binary compound contains only two elements. A compound with a polyatomic ion can contain three or more elements because a polyatomic ion can have two or more elements.)*

Explain

Binary Ionic Compounds

USE MODELS Cut index cards to obtain pieces that are one-third and two-thirds of a card. Keep some cards whole. On some whole cards, mark three large positive signs; on others, mark three large negative signs. Mark some of the one-third pieces with single positive signs; others with single negative signs. Mark the two-thirds pieces with two positive signs or two negative signs. On the opposite side of each card, write the formula for an ion having the appropriate charge. Have students match single positive and negative signs. Have them match double positive signs with double negative signs and with two single positive signs. Continue with all possible combinations. Then have students turn the cards over to see the formulas of the ionic compounds they produced.

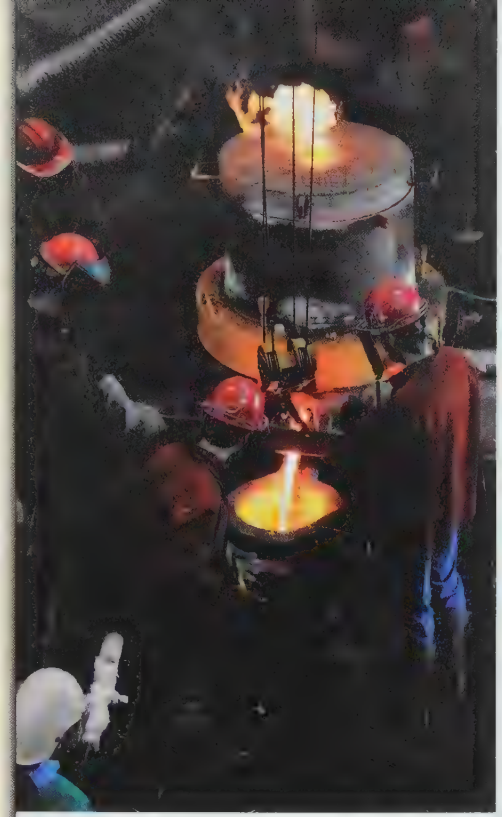

Figure 9.8 Steelworks
In the process for making steel, iron is extracted from hematite, an ore containing iron(III) oxide.
Apply Concepts ***What is the formula for iron(III) oxide?***

READING SUPPORT

Build Reading Skills: *Compare and Contrast* As you read about ionic and molecular compounds, compare the procedures for naming and writing formulas for each. ***How can you tell the difference between an ionic and a molecular compound?***

Writing Formulas for Binary Ionic Compounds

A **binary compound** is composed of two elements. Binary compounds can be ionic compounds or molecular compounds. If you know the name of a binary ionic compound, you can write the formula. **To write the formula of a binary ionic compound, first write the symbol of the cation and then the anion. Then add subscripts as needed to balance the charges.** The positive charge of the cation must balance the negative charge of the anion so that the net ionic charge of the formula is zero. The ionic compound potassium chloride is composed of potassium cations (K^+) and chloride anions (Cl^-), so potassium chloride is a binary ionic compound. The charge of each K^+ cation is balanced by the charge of each Cl^- anion. So, in potassium chloride, the potassium and chloride ions combine in a 1:1 ratio. Thus, the formula for potassium chloride is KCl. The net ionic charge of the formula unit is zero.

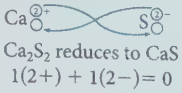
The binary ionic compound calcium bromide is composed of calcium cations (Ca^{2+}) and bromide anions (Br^-). The two ions do not have equal numerical charges. Thus, each calcium ion with its 2+ charge must combine with (or be balanced by) two bromide ions, each with a 1− charge. That means that the ions must combine in a 1:2 ratio, so the formula for calcium bromide is $CaBr_2$. The net ionic charge of the formula unit is zero.

Figure 9.8 shows one step in the process of making steel from iron ore. Hematite, a common ore of iron, contains iron(III) oxide. What is the formula for this compound? Recall that a Roman numeral in the name of an ion shows the charge of the metal ion. Thus, iron(III) oxide contains Fe^{3+} cations combined with oxide anions (O^{2-}). How can you balance a 3+ charge and a 2− charge? You must find the least common multiple of the charges, which is 6. Iron's three charges taken two times equals six ($3 \times 2 = 6$). Oxygen's two charges taken three times also equals six. Thus, two Fe^{3+} cations (a 6+ charge) will balance three O^{2-} anions (a 6− charge). The balanced formula, then, is Fe_2O_3.

Another approach to writing a balanced formula for a compound is to use the crisscross method. In this method, the numerical value of the charge of each ion is crossed over and becomes the subscript for the other ion. Notice that the signs of the charges are dropped.

$$Fe^{2+}\ O^{2-}$$
$$Fe_2O_3$$
$$2(3+) + 3(2-) = 0$$

The formula is correct because the overall charge of the formula is zero, and the subscripts are expressed in the lowest whole-number ratio.



Differentiated Instruction

LPR LESS PROFICIENT READERS Have students rewrite the answers to the key question as steps in a process. Ask students to identify each step as it is encountered in examples in the text. Allow students to keep these rules handy as they work through the lesson, until the processes become automatic.

L1 STRUGGLING STUDENTS Rewrite the Fe_2O_3 and CaS examples on the board, without the arrows. Guide students through each example step-by-step. Then, write a third pair of ions on the board and have students guide you step-by-step through this example.

L3 ADVANCED STUDENTS Have students research the possible mechanisms for the alleviation of symptoms of mental disorders, such as bipolar disorder, by lithium ions. Challenge students to explain why other Group 1A ions, such as sodium and potassium, which are normally present in substantial concentrations in the body, do not have the same effects as lithium ions even though they have the same charge.

If you use the crisscross method to write the formula for some compounds such as calcium sulfide (Ca^{2+} and S^{2-}), you will obtain the result Ca_2S_2. However, the 2:2 ratio of calcium and sulfide ions is not the lowest whole-number ratio. The correct formula for calcium sulfide is CaS.

Ca_2S_2 reduces to CaS

$1(2+) + 1(2-) = 0$

Of course, if the magnitudes of the charges of the cation and anion are the same, as they are in this case, the ions combine in a 1:1 ratio, and the charges are balanced.

Sample Problem 9.2

Writing Formulas for Binary Ionic Compounds

Write formulas for the following binary ionic compounds.

a. copper(II) sulfide **b.** potassium nitride

1 Analyze **Identify the relevant concepts.** Binary ionic compounds are composed of a monatomic cation and a monatomic anion. The symbol for the cation appears first in the formula for the compound. The ionic charges in an ionic compound must balance, and the ions must be combined in the lowest whole-number ratio.

2 Solve **Apply the concepts to this problem.**

Write the symbol and charge for each ion in the compound—the cation first, then the anion.

a. Cu^{2+} and S^{2-} | **b.** K^+ and N^{3-}

The crisscross method is used in the following solutions.

Balance the formula using appropriate subscripts. Make sure that the formula expresses the lowest whole-number ratio of ions.

Check that the charges of the two ions add up to zero.

$1(2+) + 1(2-) = 0$ | $3(1+) + 1(3-) = 0$

10. Write formulas for compounds formed from these pairs of ions.

a. Ba^{2+}, S^{2-} **c.** Ca^{2+}, N^{3-}
b. Li^{-}, O^{2-} **d.** Cu^{2+}, I^{-}

11. Write formulas for the following ionic compounds.

a. sodium iodide **c.** potassium sulfide
b. stannous chloride **d.** calcium iodide

Remember to add subscripts to make the compound neutral.

Foundations for Math

ADDITIVE INVERSES Remind students that the additive inverse of a number is its opposite and that the sum of a number and its additive inverse is 0. For example, the additive inverse of 6 is –6, and 6 + (–6) = 0. When writing the formula for a binary ionic compound, encourage students to use additive inverses to arrive at a net charge of 0.

In **Sample Problem 9.2b,** the additive inverse of 3– is 3+. Since potassium has a charge of 1+ (K^+), the formula for potassium nitride will require three potassium cations, resulting in a total charge of 3(1+) = 3+. If only one nitrogen anion is present, this will yield a net charge of 0 since 3– and 3(1+) = 3+ are additive inverses.

Teacher Demo

Making and Naming an Ionic Compound

PURPOSE Students will see a reaction in which an ionic compound is formed and then name the compound and write its formula.

MATERIALS 1 g powdered zinc (Zn), 4 g iodine (I_2), watch glass, eyedropper, 8 mL water

SAFETY Wear goggles and perform the demo in a fume hood. Place the zinc iodide in a plastic or cardboard container and dispose of it in an approved landfill site.

PROCEDURE Wear safety goggles and use a fume hood. Mix 1 g of powdered Zn and 4 g of I_2 on a watch glass. With an eyedropper, carefully add 8 mL of water, one drop at a time. After the reaction is complete, show students the zinc iodide that was formed. Write the formula unit for zinc iodide (ZnI_2) along with its name on the chalkboard. **Ask** What happened to elemental Zn and I_2 during the reaction? *(Zinc and iodine reacted to form an ionic compound composed of Zn^{2+} and I^- ions.)* Use the criss-cross method to show how the formula unit for zinc iodide was derived. Why is ZnI_2 named zinc iodide and not zinc(II) iodide? *(Zinc forms only one ion.)*

EXPECTED OUTCOME The masses of Zn and I_2 are the stoichiometic amounts. The reactants should be used up and white, crystalline ZnI_2 should form.

Sample Practice Problem

Write formulas for these compounds.

a. lithium fluoride *(LiF)*
b. aluminum chloride *($AlCl_3$)*
c. sodium nitride *(Na_3N)*
d. ferric oxide *(Fe_2O_3)*

Answers

Naming Ionic Binary Compounds

CHEMISTRY & YOU No, sodium sulfite is not a binary compound because it is comprised of more than two elements.

Explore

Class Activity

PURPOSE Students will practice naming binary compounds.

MATERIALS chalkboard or whiteboard, chalk or markers

PROCEDURE Divide the class into teams. Have each team write the names of ionic compounds on a sheet of paper as you write formulas on the board. Use chlorides, bromides, phosphides, and oxides of the elements of Groups 1A, 2A, and aluminum in 3A. Mix in sulfides, oxides, chlorides, and bromides of lead, tin, iron, cobalt, copper, and zinc. Have the teams compare their lists of names. When a discrepancy occurs, have them discuss it and come to agreement on the correct name.

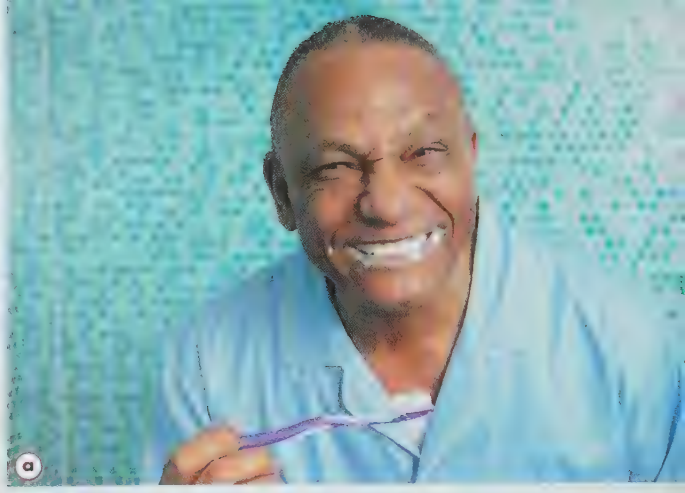

Figure 9.9 Tin Compounds
Tin(II) fluoride and tin(IV) oxide have different compositions and uses. **a.** Tin(II) fluoride is added to some toothpastes to prevent cavities. **b.** Tin(IV) oxide is used in glazes for pottery.
Identify *What are the charges of the tin ions in the two compounds?*

See some everyday chemical names online.

CHEMISTRY & YOU

Q: *Many companies use sodium sulfite (Na_2SO_3) to keep dried fruit looking delicious. Is Na_2SO_3 a binary compound? Explain.*

Naming Binary Ionic Compounds If you know the formula for a binary ionic compound, you can write its name. First you must verify that the compound is composed of a monatomic metallic cation and a monatomic nonmetallic anion. **To name any binary ionic compound, place the cation name first, followed by the anion name.** For example, the compound Cs_2O is composed of the metal cesium and the nonmetal oxygen. Both cesium and oxygen are Group A elements that have only one charge. The name of Cs_2O, then, is cesium oxide. Similarly, the name of NaBr is sodium bromide, and the name of SrF_2 is strontium fluoride.

But suppose you want to name the binary ionic compound CuO. Following the rule above, you would name this compound copper oxide. However, the name *copper oxide* is incomplete. Recall that copper commonly forms two cations: Cu^+ and Cu^{2+}. The names of these ions are copper(I) ion and copper(II) ion, respectively. How can you tell which of these cations forms the compound CuO? Working backward will help. The formula indicates that the copper cation and the oxide anion combine in a 1:1 ratio. You know that the oxide anion always has a 2− charge. Therefore, the charge of the copper cation must be 2+ in order to balance the 2− charge. The compound CuO must be copper(II) oxide. **If the metallic element in a binary ionic compound has more than one common ionic charge, a Roman numeral must be included in the cation name.**

Table 9.2 lists the symbols and names of the common metals that form more than one cation. Recall that the charges of monatomic anions can be determined from the periodic table. Using these two sources, you can write the names of SnF_2 and SnS_2. Tin (Sn) forms cations with 2+ and 4+ charges. Fluorine is a Group 7A element, so the charge of the fluoride ion is 1−. In SnF_2, the ratio of cations to anions is 1:2. Therefore, the charge of the tin cation must be 2+ to balance the combined 2− charge of two fluoride ions. The name of SnF_2 is tin(II) fluoride or stannous fluoride. However, the name of SnO_2 is not tin(II) oxide. Oxygen is a Group 6A element, so its charge is 2−. The charge of the tin cation must be 4+ to balance the combined charges of two oxide anions. Thus, the name of SnO_2 is tin(IV) oxide or stannic oxide. Figure 9.9 shows examples of uses of stannous fluoride and stannic oxide.

Professional Development Note

Lattice Energy in Ionic Bonding

Ionic compounds tend to be stable—energy in the form of heat or electricity is needed to decompose them. Thus, energy must be released when ionic bonds form. But the released energy is not primarily from the transfer of electrons. Forming a cation is an endothermic process. In addition, both the metal and the nonmetal must be vaporized—another endothermic process—before electron transfer can take place. Some energy (electron affinity) is released when the nonmetal gains one or more electrons, but this is not enough to make the entire process exothermic. It is lattice energy that makes the difference. Lattice energy is the energy released when gaseous cations and anions settle into the orderly crystal structure characteristic of a solid ionic compound.

Sample Problem 9.3

Naming Binary Ionic Compounds

Name the following binary ionic compounds:

a. CoI_2 **b.** Li_2Se

1 Analyze **Identify the relevant concepts.** Confirm that the compound is a binary ionic compound. To name the compound, name the ions in the order written in the formula—the cation name followed by the anion name. The name of a metal ion that has more than one common ionic charge must include a Roman numeral indicating the charge.

2 Solve **Apply the concepts to this problem.**

	a. CoI_2	**b.** Li_2Se
Interpret the chemical formula in terms of component elements. If you find two elements, the compound is binary.	CoI_2 contains cobalt cations and iodide anions.	Li_2Se contains lithium cations and selenide anions.
Determine whether the metal ion in the compound has more than one common ionic charge.	Cobalt forms two common cations: Co^{2+} and Co^{3+}.	Lithium forms one cation: Li^+.
If the metal ion has more than one ionic charge, use the nonmetal anion to determine which cation is indicated by the formula.	Iodide ion is I^-. The formula CoI_2 specifies two iodide ions, which give a charge of 2−. So the cobalt ion must be Co^{2+} to balance the charge.	This step is not needed for Li_2Se because the lithium ion has only one common charge.
Write the name of the cation, followed by the name of the anion. Include Roman numerals as needed.	cobalt(II) iodide	lithium selenide

12. Name the following binary ionic compounds:

a. ZnS **c.** BaO
b. KCl **d.** $CuBr_2$

13. Write the names for these binary ionic compounds.

a. CaO **c.** FeS
b. Cu_2Se **d.** AlF_3

Explain

USE A MODEL Make sure students understand the concept of "electrically neutral" by using a model to indicate cations and anions. Have them use the model each time they write the formula for a binary ionic compound. Models can be a balance, colored chips, stackable blocks, etc. **Ask** Why must the positive charges + the negative charges equal zero? *(Compounds have a neutral charge.)*

Explore

Class Activity

PURPOSE Students become more proficient in writing formulas.

MATERIALS lists of names of ionic compounds generated in the class activity on page 274

PROCEDURE Have teams of students write the formulas for the names on the lists. When the formulas on two or more lists do not agree, have the teams resolve the discrepancy by using the criss-cross method to write the formula on the board.

Sample Practice Problem

Write the names for these binary compounds.

a. Na_2O *(sodium oxide)*
b. Mg_3N_2 *(magnesium nitride)*
c. NaF *(sodium fluoride)*
d. K_3N *(potassium nitride)*

UbD Check for Understanding

How do you determine the formula and name of a binary ionic compound?

Assess students' knowledge about naming and writing binary ionic compounds by asking the following questions. **Ask** When naming a binary compound, what comes first, the anion or the cation? *(cation first, followed by anion)* **Ask** What is the purpose of subscripts in the formula for a binary ionic compound? *(They neutralize the difference in the charges between the cation and the anion.)*

ADJUST INSTRUCTION If students are having trouble answering, have them review Sample Problems 9.2 and 9.3. Then, use the formulas in each problem to walk students through the answers of the two questions.

Answers

FIGURE 9.9 2+ and 4+, respectively

12. **a.** zinc sulfide **b.** potassium chloride
c. barium oxide **d.** copper(II) bromide

13. **a.** calcium oxide **b.** copper(I) selenide
c. iron(II) sulfide **d.** aluminum fluoride

Explain

Compounds with Polyatomic Ions

USE VISUALS Direct students to the photographs in Figure 9.10. Tell students that the real-world items shown are only two of many polyatomic ions they encounter in their daily lives. Discuss some other common examples. **Ask** What are the formulas for calcium carbonate, lead(II) sulfate, ammonium sulfate, and ammonium phosphate? *($CaCO_3$, $PbSO_4$, $(NH_4)_2SO_4$, $(NH_4)_3PO_4$)*

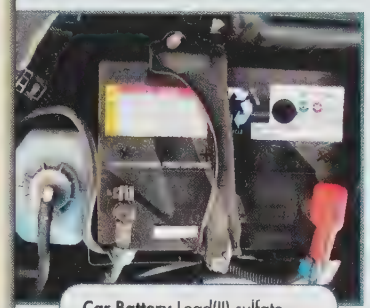
Explore

Teacher Demo

PURPOSE Students will watch the formation of an ionic precipitate and postulate possible formulas.

MATERIALS 50 mL 0.1*M* lead(II) nitrate, 50 mL 0.1*M* sodium carbonate, 100-mL beaker

PROCEDURE Wear goggles and gloves. Slowly mix the two solutions. Make sure students see the precipitate of lead carbonate that forms. Write on the board the symbols or formulas for the four ions that are in the two solutions: Pb^{2+}, NO_3^-, Na^+, and CO_3^{2-}. Tell students that the two solutions contained these four ions and that the precipitate is an ionic compound formed by the combination of two of them. **Ask** students to list all possible formula units for the solid and to name each possibility. Identify the solid as lead(II) carbonate ($PbCO_3$).



SAFETY Wear goggles and gloves because lead(II) nitrate is toxic. For disposal, combine the reaction mixture with 10 g of solid NaCl in a beaker. Stir the solution and allow the precipitate to settle. Filter or decant to isolate the precipitate. Place the dry precipitate in a plastic or cardboard container and dispose of it in an approved landfill. Flush the filtrate down the drain with excess water.

Compounds With Polyatomic Ions

How do you determine the formula and name of a compound with a polyatomic ion?

The seashells shown in Figure 9.10 are made of calcium carbonate ($CaCO_3$). Calcium carbonate is obviously not a binary compound because it contains more than two elements. Remember that an *-ate* or *-ite* ending on the name of a compound indicates that the compound contains a polyatomic anion that includes oxygen. Calcium carbonate contains one monatomic ion (Ca^{2+}) and one polyatomic ion (CO_3^{2-}). Figure 9.10 also shows a typical automobile battery called a lead storage battery. The energy-producing reaction inside the battery uses the ionic compound lead(II) sulfate ($PbSO_4$), which consists of the monatomic ion Pb^{2+} and the polyatomic ion SO_4^{2-}.

Figure 9.10
Compounds With Polyatomic Ions
Some examples of ionic compounds that contain polyatomic ions are shown.
Explain *Why is there a Roman numeral in the name lead(II) sulfate?*

Car Battery Lead(II) sulfate ($PbSO_4$) is formed when an automobile battery discharges.

Writing Formulas for Compounds With Polyatomic Ions

How would you write the formula for an ionic compound with a polyatomic ion? For starters, try following the same procedure you used for binary ionic compounds. **To write the formula for a compound with a polyatomic ion, first write the symbol (or formula) for the cation followed by the symbol (or formula) for the anion. Then, add subscripts as needed to balance the charges.** For example, calcium nitrate is composed of a calcium cation (Ca^{2+}) and a polyatomic nitrate anion (NO_3^-). In calcium nitrate, two nitrate anions, each with a 1− charge, are needed to balance the 2+ charge of each calcium cation.

$$Ca^{2+}\ (NO_3)^{-}_{2}$$
$$Ca(NO_3)_2$$
$$1(2+) + 2(1-) = 0$$

The charge is balanced and the ions are expressed in the lowest whole-number ratio, so the formula is correct. Parentheses are used around the nitrate ion in the formula because more than one nitrate anion is needed. The subscript 2 that follows the parentheses shows that the compound contains two nitrate anions. **Whenever more than one polyatomic ion is needed to balance the charges in an ionic compound, use parentheses to set off the polyatomic ion in the formula.**

Go online to make and name some ionic compounds. VIRTUAL LAB

Shells The shells of marine organisms are composed of calcium carbonate ($CaCO_3$).

Professional Development Note

Lithium Carbonate as Medication

When John Cade, a doctor in the Victoria Department of Mental Health in Victoria, Australia, injected guinea pigs with a lithium salt of uric acid in 1949, he found that the usually hyperactive animals became calm and lethargic for a period of time. After further experimentation, Cade injected a severely disturbed patient with lithium carbonate. The results were so astonishingly positive for this patient, and for many others who followed, that within 10 years the treatment had spread throughout Europe and into the United States. Patients who had been confined to mental institutions for virtually their entire lives were able to return to normal living.

Lithium carbonate is a compound that can be prescribed for patients who have mood disorders, such as manic-depressive disorder or bipolar disorder. The compound is composed of lithium cations (Li^+) and polyatomic carbonate anions (CO_3^{2-}). In the formula for lithium carbonate, two lithium cations, each with a 1+ charge, are needed to balance the 2− charge of one carbonate anion. Parentheses are not needed to set off the polyatomic carbonate anion.

Li_2CO_3

$2(1+) + 1(2-) = 0$

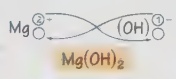
Strontium sulfate is another example of a compound in which only a single polyatomic ion (SO_4^{2-}) is needed to balance the cation (Sr^{2+}). So, no parentheses are needed when writing the formula: $SrSO_4$.

SampleProblem 9.4

Writing Formulas for Compounds With Polyatomic Ions

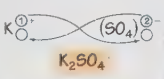
What are the formulas for these ionic compounds?

a. magnesium hydroxide **b.** potassium sulfate



1 Analyze **Identify the relevant concepts.** Write the symbol or formula for each ion in the order listed in the name. Use subscripts to balance the charges. The ions must be combined in the lowest whole-number ratio. If more than one polyatomic ion is needed to balance a formula, place the polyatomic ion formula in parentheses, followed by the appropriate subscript.

2 Solve **Apply the concepts to this problem.**

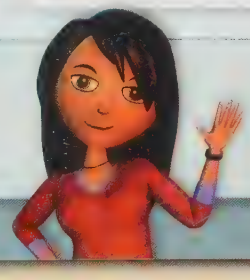


Write the symbol or formula for each ion in the compound—the cation first, then the anion. Include the charge for each ion.

a. cation: Mg^{2+} anion: OH^- **b.** cation: K^+ anion: SO_4^{2-}

Balance the formula using appropriate subscripts. Make sure that the formula expresses the lowest whole-number ratio of ions.

$Mg(OH)_2$



K_2SO_4

Remember: Only use parentheses if there is more than one polyatomic ion in the balanced formula.

Check that the charges of the two ions add up to zero.

$1(2+) + 2(1-) = 0$ $2(1+) + 1(2-) = 0$

14. Write formulas for compounds formed from these pairs of ions.
a. NH_4^+, SO_3^{2-}
b. calcium ion, phosphate ion

15. Write formulas for the following compounds:
a. lithium hydrogen sulfate
b. chromium(III) nitrite

Foundations for Math

READING PARENTHESES AND CHARGES When a formula contains parentheses, students may be confused by standard rules of exponents that they have learned in math. For example $(2x)^3$ in math means 2^3x^3—the exponent is applied to both the 2 and the x inside the parentheses. Stress that this is not the case when a charge has been assigned to a polyatomic ion. The charge is the total charge for the entire ion and is not distributed to each element in the parentheses.

In **Sample Problem 9.4b,** $(SO_4)^{2-}$ has a total charge of 2−. The 2− is NOT an exponent and is NOT distributed inside the parentheses. A common error would be for students to assign a total charge of 4− to the ion because there are two elements.

Explain

Misconception Alert

Students may confuse whole numbers and integers. Make sure students understand that the set of whole numbers is the set of natural numbers and zero, whereas the set of integers consist of whole numbers, zero, and their opposites. Point out that a whole number ratio means that the numbers in the ratio will be positive values. Emphasize that decimals and fractions are not considered whole numbers.

MAKE A CONNECTION Explain to students that magnesium hydroxide is a suspension of magnesium hydroxide ($Mg(OH)_2$) in water and is useful as an antacid and laxative. It is an ionic compound with a polyatomic ion. Its common name is milk of magnesia. Explain that in the stomach, the hydroxide ion reacts with excess acid that causes the discomfort of indigestion. In larger amounts, magnesium hydroxide also acts as a muscle relaxant and relieves constipation.

Sample Practice Problem

Write formulas of compounds formed from these pairs of ions:

a. Pb^{2+}, NO_3^- ($Pb(NO_3)_2$)
b. iron(III) ion and sulfate ion ($Fe_2(SO_4)_3$)
c. Cr^{3+}, OH^- ($Cr(OH)_3$)
d. sodium ion and hydrogen phosphate ion (Na_2HPO_4)

Answers

FIGURE 9.10 to specify the charge (Lead can have a 2+ charge or a 4+ charge.)

14. **a.** $(NH_4)_2SO_3$ **b.** $Ca_3(PO_4)_2$
15. **a.** $LiHSO_4$ **b.** $Cr(NO_2)_3$

Explain

Sample Practice Problem

Name the following compounds.

a. FeN *(iron(III) nitride)*

b. $Mg(NO_3)_2$ *(magnesium nitrate)*

Extend

Divide the class into groups of three to four students. Have students take turns randomly choosing ions from Tables 9.2 and 9.3 in Lesson 9.1. The other member or the group must write the formula and name the compound. All students in the group should agree on the names and formulas.

Evaluate

Informal Assessment

Write the following cations on one side of the board: NH_4^+, Mg^{2+}, and Pb^{4+}. Write the following anions on the other side of the board: Br^-, S^{2-}, and PO_4^{3-}. Ask students to write formula units for all the possible ionic compounds that these ions could form and name them. Ask them to explain how they arrived at their answers. Then have students complete the 9.2 Lesson Check.

Reteach

Review the lesson with students and help them to organize the information so that the three key items to consider when naming an ionic compound are apparent: (1) the identity of the ions, (2) the order of the names, and (3) the possibility that an element may form cations with more than one charge. Make sure students note that for binary compounds, ions can be identified from their symbols. The suffix *-ide* is used when naming the nonmetal ion, and for compounds with polyatomic ions, the polyatomic ion name can be obtained from Table 9.3 in Lesson 9.1. Students should also note that the name of the cation always precedes the name of the anion. Explain that for elements that form more than one cation, the correct charge is shown by a Roman numeral in parentheses directly after the cation name.

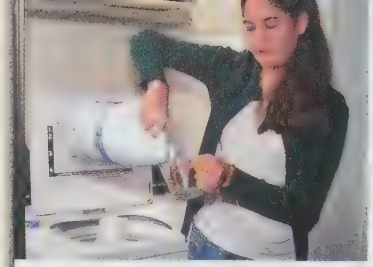


Figure 9.11 Sodium Hypochlorite The compound NaClO is often added to laundry water to bleach (brighten) white fabrics.

Naming Compounds With Polyatomic Ions You have learned to write formulas for compounds containing polyatomic ions when you were given their names. Now, if you were given the formulas for these compounds, could you name them? When naming compounds containing polyatomic ions, you must first identify any polyatomic ions in the formula for the compound. If the polyatomic ion is unfamiliar, find its name in Table 9.3. **To name a compound containing a polyatomic ion, state the cation name first and then the anion name. If the cation is a metallic element that has more than one common ionic charge, include a Roman numeral in the cation name.** Recall that the same rules apply when naming binary ionic compounds.

The compound NaClO is used as a disinfectant for swimming pools and as a bleach, as shown in Figure 9.11. The cation in this compound is sodium ion (Na^+). The other ion, ClO^-, is a polyatomic ion called hypochlorite ion. So, the name for NaClO is sodium hypochlorite.

SampleProblem 9.5

Naming Compounds With Polyatomic Ions

Name the following ionic compounds:

a. $(NH_4)_2C_2O_4$ **b.** $Fe(ClO_3)_3$

1 Analyze **Identify the relevant concepts.** Determine whether there is a polyatomic ion in the formula. To name the compound, list the names of the ions in the order written in the formula—the cation name followed by the anion name. The name of an ion that has more than one common ionic charge must include a Roman numeral indicating the charge.

2 Solve **Apply the concepts to this problem.**

	a. NH_4^+ and $C_2O_4^{2-}$	b. ClO_3^-
Identify any polyatomic ions.		
Determine if any metal ions in the compound have more than one common ionic charge. If so, use the nonmetal anion to determine which cation is indicated by the formula.	This step is not needed because there is no metal ion in this compound.	Iron forms two common cations: Fe^{2+} and Fe^{3+}. Chlorate ion is ClO_3^-. Three chlorate ions give a charge of 3−. So the iron ion must be Fe^{3+} to balance the charge.
Write the name of the cation, then the name of the anion. Include Roman numerals as needed.	ammonium oxalate	iron(III) chlorate

16. Name the following ionic compounds:

a. CaC_2O_4 **c.** $KMnO_4$

b. KClO **d.** Li_2SO_3

17. Write the names for these ionic compounds.

a. $Al(OH)_3$ **c.** $Sn_3(PO_4)_2$

b. $NaClO_3$ **d.** Na_2CrO_4

Focus on ELL

4 LANGUAGE PRODUCTION Have students work in groups of four to complete the lab. Make sure each group has ELLs of varied language proficiencies, so that more proficient students can help less proficient ones. Have students work according to their proficiency level.

BEGINNING

LOW Have students be in charge of test tube *C*. Students can mimic other students working with test tubes *A* and *B*.

HIGH Have students draw pictures of their observations or use symbols to note their observations.

INTERMEDIATE: LOW/HIGH Provide students with a chart they can use to record their observations. Include a box students can check for "dissolved" or "did not dissolve."

ADVANCED: LOW/HIGH Have students assist students with lower English proficiencies with writing the formulas. Have students read the names and the formulas aloud.

Quick Lab

Purpose To mix solutions containing cations and anions to make ionic compounds

Making Ionic Compounds

Materials

- 9 small test tubes
- test tube rack
- paper, pencil, ruler
- 6 droppers
- solution A (Fe^{3+} ion)
- solution B (Ag^{+} ion)
- solution C (Pb^{2+} ion)
- solution X (CO_3^{2-} ion)
- solution Y (OH^{-} ion)
- solution Z (PO_4^{3-} ion)

Procedure

1. Label three test tubes A, three test tubes B, and three test tubes C.
2. Add 10 drops (approximately 0.5 mL) of solution A to the test tubes that are labeled A. Add 10 drops of solution B to the test tubes that are labeled B. Repeat this step with solution C.
3. Add 10 drops of solution X to one test tube of A, 10 drops to one test tube of B, and 10 drops to one test tube of C. Observe each test tube for the formation of a solid.
4. Make a 3-by-3 inch grid to record your observations. Label the rows A, B, and C. Label the columns X, Y, and Z. Describe any solid material you observe.
5. Repeat Step 3, adding 10 drops of solution Y to test tubes A, B, and C. Record your observations.
6. Repeat Step 3, adding 10 drops of solution Z to test tubes A, B, and C. Record your observations.

Analyze and Conclude

1. **Infer** Some ionic compounds are insoluble in water. What did you observe? How many of the compounds formed were insoluble?
2. **Describe** Write the formula for each ionic compound formed.
3. **Describe** Name each ionic compound formed.
4. **Draw Conclusions** Will mixing any cation with any anion always lead to the formation of an insoluble ionic compound? Explain your answer.

9.2 LessonCheck

18. **Summarize** Describe the procedures for writing the formulas and names of binary ionic compounds.
19. **Review** How do you write the formulas and the names of compounds with polyatomic ions?
20. **Evaluate** What are the advantages and disadvantages of common names?
21. **Apply Concepts** Write the formula for these binary ionic compounds.
    a. beryllium chloride
    b. cesium sulfide
    c. sodium iodide
    d. strontium oxide
22. **Identify** What condition must be met when writing a formula for an ionic compound?
23. **Apply Concepts** Write the formula for these compounds containing polyatomic ions.
    a. chromium(III) nitrite
    b. sodium perchlorate
    c. magnesium hydrogen carbonate
    d. calcium acetate
24. **Explain** When do you use parentheses in writing a chemical formula?
25. **Describe** Name the following ionic compounds:
    a. LiF
    b. SnS_2
    c. $MnCO_3$
    d. $Sr(H_2PO_4)_2$
26. **Identify** Which of the following formulas are incorrect? Explain your answer.
    a. $Mg_2(SO_4)_3$
    b. $AsRb_3$
    c. $BeCl_3$
    d. NaF

Lesson Check Answers

18. Write the symbol for the cation then the symbol for the anion. Balance the charges. Write the cation name then the anion name.
19. Write the symbol or formula for the cation then the symbol or formula of the anion. Balance the charges. Name the cation first followed by the anion.
20. Most common names do not tell you about the chemical composition of a compound. Many common names indicate other physical characteristics of the compound.
21. a. $BeCl_2$ b. Cs_2S c. NaI d. SrO
22. The charges of the ions must balance.
23. a. $Cr(NO_2)_3$ b. $NaClO_4$ c. $Mg(HCO_3)_2$ d. $Ca(C_2H_3O_2)_2$
24. when the compound contains more than one of a particular polyatomic ion
25. a. lithium fluoride
    b. tin(IV) sulfide
    c. manganese(II) carbonate
    d. strontium dihydrogen phosphate
26. a. incorrect; charges are not balanced, $MgSO_4$
    b. incorrect; anion symbol should be second, Rb_3As
    c. incorrect; charges are not balanced, $BeCl_2$

Quick Lab

PURPOSE Students form precipitates and write their formulas and names.

SKILLS FOCUS observing, applying rules

PREP TIME 30 minutes

CLASS TIME 20 minutes

ADVANCED PREPARATION

Solution	Preparation
0.05*M* $AgNO_3$	2.1 g in 250 mL
0.2*M* $Pb(NO_3)_2$	16.6 g in 250 mL
1.0*M* $NaCO_3$	26.5 g in 250 mL
0.5*M* NaOH	5.0 g in 250 mL
0.1*M* $Na_3(PO_4)_2$	9.5 g $Na_3PO_4 \cdot 12H_2O$ in 250 mL
0.1*M* $FeCl_3$	6.8 g $FeCl_3 \cdot 6H_2O$ in 25 mL of 1.0*M* NaCl; dilute to 250 mL

ANALYZE AND CONCLUDE

1. An insoluble compound formed in every tube.
2. $Fe_2(CO_3)_3$, $Fe(OH)_3$, $FePO_4$, Ag_2CO_3, AgOH, Ag_3PO_4, $PbCO_3$, $Pb(OH)_2$, $Pb_3(PO_4)_2$
3. iron(III) carbonate, iron(III) hydroxide, iron(III) phosphate, silver carbonate, silver hydroxide, silver phosphate, lead(II) carbonate, lead(II) hydroxide, lead(II) phosphate
4. No, NaCl, for example, is soluble.

Answers

16. a. calcium oxalate
    b. potassium hypochlorite
    c. potassium permanganate
    d. lithium sulfite
17. a. aluminum hydroxide
    b. sodium chlorate
    c. tin(II) phosphate
    d. sodium chromate

LESSON 9.3

Key Objectives

9.3.1 APPLY the rules for naming and writing formulas for binary molecular compounds.

Additional Resources

Reading and Study Workbook, Lesson 9.3

Available online or DVD-ROM:

- Lesson 9.3 Review

PearsonChem.com

Engage

CHEMISTRY & YOU Have students read the opening text. **Ask** Do you know of any chemicals that use prefixes in their names? *(Sample answers: carbon dioxide, carbon monoxide)* Point out that these compounds have prefixes attached to the second component of the chemical, but that prefixes can also be attached to the first component as well. Have students speculate as to what information the prefixes provide about the compounds students named at the beginning of this activity.

Activate Prior Knowledge

Remind students that, earlier in this course, they encountered metric prefixes such as *milli-*, *centi-*, and *kilo-*. Point out that both *milli-* and *centi-* represent fractional amounts, while *kilo-* represents a whole number amount. Explain that, in this lesson, students will encounter prefixes that represent small whole numbers.

IN ACADEMIC STANDARDS for SCIENCE

C.3.4 Draw structural formulas for and name simple molecules.

9.3 Naming and Writing Formulas for Molecular Compounds

C.3.4 Structural formulas and names

CHEMISTRY & YOU

Q: *What numerical prefixes are used in chemistry?* You're already familiar with words containing numerical prefixes. For example, the word *triathlon* contains the prefix *tri-*, indicating the number 3. Athletes sometimes compete in multisport events—pentathlons, heptathlons, decathlons, and so on. The prefix of each tells you how may sports are in the event. Prefixes are used in chemistry, too. In this lesson, you will learn how prefixes in the name of a binary molecular compound tell you its composition.

Key Question

What guidelines are used to write the name and formula of a binary molecular compound?

CHEMISTRY & YOU

***Q:** How does a triathlon differ from a pentathlon? How does phosphorus trifluoride differ from phosphorus pentafluoride?*

Binary Molecular Compounds

What guidelines are used to write the name and formula of a binary molecular compound?

Recall that binary ionic compounds are composed of the ions of two elements, a metal and a nonmetal. Binary molecular compounds are also composed of two elements, but both elements are nonmetals and are not ions. These differences affect the naming of these compounds and the writing of their formulas. Binary molecular compounds are composed of molecules, not ions, so ionic charges cannot be used to write formulas or to name them.

When two nonmetallic elements combine, they often do so in more than one way. For example, the elements carbon and oxygen combine to form two gaseous compounds, CO and CO_2. How would you name a binary compound formed by the combination of carbon and oxygen atoms? It might seem satisfactory to call it carbon oxide. However, the two carbon oxides, CO and CO_2, are very different compounds. Sitting in a room with small amounts of CO_2 in the air would not present any problems. You exhale CO_2 as a product of your body chemistry, as shown in Figure 9.12. Thus, it is normally present in the air you breathe. On the other hand, if the same amount of CO were in the room, you could die of asphyxiation. The binary compound CO is a poisonous gas that interferes with your blood's ability to carry oxygen to body cells. Obviously, a naming system that distinguishes between these two compounds is needed.

Focus on ELL

1 CONTENT AND LANGUAGE Write the word *guideline* on the board and pronounce it for the class. Have students locate this word in the text. *(Students should notice that* guideline *is used in the key question and its answer.)* Have students use context clues to define the term. *(A guideline is similar to a rule.)* Add this word to the word wall.

2 FRONTLOAD THE LESSON Preview the prefixes in Table 9.4. Ask student pairs to make a list of familiar words that use these prefixes. Have each pair share their words (and meanings) with the class. Students should add to their list when another pair states a word that is not on their list. Have students keep these examples in mind as they proceed with the lesson.

3 COMPREHENSIBLE INPUT When explaining Sample Problems 9.6 and 9.7, use the same highlighter color to highlight the number 2 and the prefix *di-*, and a different color to highlight the number 1 and the prefix *mono-*. Encourage students to expand on and use this color-coding method during independent practice.

Naming Binary Molecular Compounds Prefixes in the names of binary molecular compounds help distinguish compounds containing different numbers of atoms such as CO and CO_2. Table 9.4 lists the prefixes used to name binary molecular compounds. These prefixes tell how many atoms of an element are present in each molecule of the compound. According to the table, the prefix *mono-* would be used for the single oxygen atom in CO. The prefix *di-* would be used to indicate the presence of the two oxygen atoms in CO_2.

Use the prefixes listed in Table 9.4 along with the following guidelines to name a binary molecular compound. But before you apply these steps, you must confirm that the compound is a binary molecular compound. **To name a binary molecular compound, use the following guidelines:**

1. **Write the names of the elements in the order listed in the formula.**
2. **Use prefixes appropriately to indicate the number of each kind of atom.** If just one atom of the first element is in the formula, omit the prefix *mono-* for that element. Also, the vowel at the end of a prefix is sometimes dropped when the name of the element begins with a vowel.
3. **End the name of the second element with the suffix *-ide*.**

Following these guidelines, CO is named carbon *mon*oxide and CO_2 is named carbon *di*oxide. What about the compound Cl_2O_8? This binary molecular compound consists of two chlorine atoms and eight oxygen atoms. The name is therefore *di*chlorine *oct*oxide.

Table 9.4

Prefixes Used in Naming Binary Molecular Compounds

Prefix	Number
mono-	1
di-	2
tri-	3
tetra-	4
penta-	5
hexa-	6
hepta-	7
octa-	8
nona-	9
deca-	10

Figure 9.12 Carbon Dioxide When you exhale underwater, bubbles containing CO_2 rise to the surface of the water.

Differentiated Instruction

L3 ADVANCED STUDENTS Increasingly large quantities of the binary molecular compound CO_2 are released into the atmosphere annually by the burning of fossil fuels. Once in the atmosphere, carbon dioxide traps infrared energy near Earth's surface. As a result, some scientists predict that over time global temperatures will rise. Ask students to learn more about global warming and prepare an oral or written report or a poster that explains the current understanding or perception of this topic.

L1 STRUGGLING STUDENTS Provide students with a copy of Table 9.4, but include an additional column so students can write a couple of examples of compounds for each row. Instruct students to use this table as a study guide.

ELL ENGLISH LANGUAGE LEARNERS Have students write out steps for writing formulas for molecular compounds in their own words. Encourage them to use symbols and examples as needed. Allow beginning speakers to include native language versions as well.

Foundations for Reading

BUILD VOCABULARY Tell students that the word *prefix* comes from the Latin word *praefigere,* meaning "to fasten before." Explain that students will learn to attach a prefix such as *di-, tri-,* or *tetra-* to the names of elements to indicate how many atoms of each element are in a formula of a molecular compound.

READING STRATEGY Encourage students to visualize the meaning of the prefixes used in binary molecular compounds. Write some names on the board: for example, carbon tetrachloride. Then, draw one circle representing carbon and four circles representing chlorine. All the circles combined constitute the five atoms in CCl_4. **Ask** How many circles should I draw for fluorine in sulfur hexafluoride? *(six)* How many circles should I draw for sulfur in sulfur hexafluoride? *(one)*

Explain

Binary Molecular Compounds

APPLY CONCEPTS Explain how the order of the elements in the names of most molecular compounds is established. Point out that ordinarily, the less electronegative element appears first in the name. For example, a compound containing carbon and sulfur is carbon disulfide (CS_2). Tell students that since carbon is less electronegative than sulfur, it appears first. Remind students that electronegativity increases from left to right on the periodic table and decreases from top to bottom. Explain that the first element in the name and formula is the element further to the left. **Ask** In the compound disulfur dichloride, S_2Cl_2, why does the sulfur appear first? *(Sulfur is less electronegative than chlorine.)* Explain that for elements in the same column, the element nearer the bottom of the table typically appears first, for example, iodine heptafluoride (IF_7).

CHEMISTRY & YOU A triathlon has three events, and a pentathlon has five events. Likewise, phosphorus trifluoride has three fluorine atoms, and phosphorus pentafluoride has five fluorine atoms.

Explore

Class Activity

PURPOSE Students will convert the subscripts in a formula to prefixes in the name.

MATERIALS paper and pencil

PROCEDURE Have students make a chart with three columns: *element name, number of atoms,* and *prefix*. Have them fill in the columns for N_2O and then name the compound. For example:

Nitrogen	2	di-
Oxygen	1	mono-

The name is dinitrogen monoxide. Write the molecular formulas for other compounds on the board and have students add them to their charts. Some possibilities are CCl_4, PBr_5, and P_4S_3.

Explain

Binary Molecular Compounds

USE AN ANALOGY Discuss how some families name a male offspring the same name as his father. Explain that this is noted by the person's full name followed by either the word junior, or by the Roman numeral of his position in the family. For instance, Eric Philip Thomas Junior indicates that he is the second male in his family with the name Eric Philip Thomas, whereas Eric Philip Thomas V indicates that he is the fifth male in his family with this name. Explain that when a person's name is original to the family, such as Wyatt Mitchell Thomas, his name is not followed by a 1st, a Roman numeral I, or the words "the original." When a number or a word does not follow a name, then it is customarily understood that the name is the first occurrence for a male in a family. Use this scenario to help explain why the prefix *mono-* is not used to indicate one atom of the first element in a binary molecular compound. Explain that when a prefix does not appear on the first element in a binary compound, it is customarily understood that there is only one atom. It would be redundant to add the prefix.

Sample Practice Problem

Write the formula for each compound.

a. dinitrogen difluoride *(N_2F_2)*

b. lead tetraiodide *(PbI_4)*

Sample Problem 9.6

Naming Binary Molecular Compounds

Name the following binary molecular compounds:

a. N_2O **b.** PCl_3

1 Analyze **Identify the relevant concepts.** Confirm that the compound is a binary molecular compound—a compound composed of two nonmetals. To name the compound, name the elements in the order written in the formula. Use prefixes as necessary to indicate the number of each kind of atom. Use the suffix *-ide* on the name of the second element.

2 Solve **Apply the concepts to this problem.**

Identify the elements in the compound and the number of atoms of each element in a molecule of the compound.

a. N_2O is composed of two nonmetals, nitrogen and oxygen.

Each molecule of N_2O has: 2 nitrogen atoms; 1 oxygen atom.

b. PCl_3 is composed of two nonmetals, phosphorus and chlorine.

Each molecule of PCl_3 has: 1 phosphorus atom; 3 chlorine atoms.

Write the names of the elements in the order they are written in the formula. Include prefixes to show how many atoms of each element. Use the suffix *-ide* with the name of the second element.

dinitrogen monoxide

phosphorus trichloride

27. Name the following binary molecular compounds:

a. OF_2 **c.** SO_3

b. S_2F_{10} **d.** SF_6

Writing Formulas for Binary Molecular Compounds Suppose you know the name of a molecular compound and want to write the formula. **To write the formula of a binary molecular compound, first use the prefixes in the name to tell you the subscript of each element in the formula. Then, write the correct symbols for the two elements with the appropriate subscripts.** An interesting example is tetraphosphorus trisulfide, which is used in some matches. The name *tetraphosphorus trisulfide* has the prefixes *tetra-* and *tri-*, so the subscripts of phosphorus and sulfur must be 4 and 3, respectively. Thus, the formula for tetraphosphorus trisulfide is P_4S_3.

Foundations for Math

PREFIXES Remind students that they probably learned prefixes in algebra or geometry. For example, the names of special polynomials involve prefixes and depend on the number of terms that make up the expression: *mono*mial (1 term), *bi*nomial (2 terms), *tri*nomial (3 terms). **Ask** Which of these prefixes is not used when naming compounds? *(bi-; the prefix when there are 2 atoms of an element is* di-*)* In geometry, the names of plane shapes are based on the number of sides: *tri*angle (3 sides), *quad*rilateral (4 sides), *penta*gon (5 sides), and so on. **Ask** Which of these prefixes is not used when naming compounds? *(quad-; the prefix when there are 4 atoms of an element is* tetra-*)*

In **Sample Problem 9.6a,** stress that the 2 atoms of nitrogen are read as *dinitrogen*, not *binitrogen*.

Sample Problem 9.7

Writing Formulas for Binary Molecular Compounds

Write formulas for the following binary molecular compounds:
a. nitrogen trifluoride **b.** disulfur dichloride

1 Analyze **Identify the relevant concepts.** The prefixes in the name indicate the subscript of each element in the formula. Write the symbols for the two elements with the appropriate subscripts.

2 Solve **Apply the concepts to this problem.**

Use the prefixes to determine how many atoms of each element are in the compound.

a. Each molecule of nitrogen trifluoride has: 1 nitrogen atom; 3 fluorine atoms.

b. Each molecule of disulfur dichloride has: 2 sulfur atoms; 2 chlorine atoms.

Construct the formula using the correct symbols and subscripts.

a. NF_3

b. S_2Cl_2

28. Write formulas for these binary molecular compounds.
a. dinitrogen tetroxide **c.** disulfur decafluoride
b. xenon tetrafluoride **d.** iodine heptafluoride

Note: The number 1 is never used as a subscript in a formula.

9.3 LessonCheck

29. Review Explain how to write the name and formula of a binary molecular compound.

30. Describe Write the names of these molecular compounds.
a. NCl_3 **c.** NI_3 **e.** N_2H_4
b. BCl_3 **d.** SO_3 **f.** N_2O_3

31. Apply Concepts Write the formulas for these binary molecular compounds.
a. phosphorus pentachloride
b. iodine heptafluoride
c. chlorine trifluoride
d. iodine dioxide

32. Describe Write the formulas or names for these molecular compounds.
a. CS_2 **c.** carbon tetrabromide
b. Cl_2O_7 **d.** diphosphorus trioxide

33. Evaluate The name a student gives for the molecular compound $SiCl_4$ is monosilicon trichloride. Is this name correct? Explain your answer.

34. Explain Are the bonds between silicon and chlorine in silicon tetrachloride single bonds? Justify your answer by drawing an electron dot structure of silicon tetrachloride.

35. Classify Determine whether each of the following compounds is a molecular compound or an ionic compound. How can you tell?
a. PBr_3 **c.** iron(III) oxide
b. KBr **d.** carbon tetraiodide

BIG IDEA BONDING AND INTERACTIONS

36. What is the difference between an ionic compound and a molecular compound?

Lesson Check Answers

29. Name the elements in the order written in the formula, using prefixes as necessary to indicate the number of each kind of atom. Then, use the suffix *-ide* on the name of the second element. Write the symbol for each element with a subscript corresponding to the prefix before each element in the name.

30. **a.** nitrogen trichloride **b.** boron trichloride **c.** nitrogen triiodide **d.** sulfur trioxide **e.** dinitrogen tetrahydride **f.** dinitrogen trioxide

31. **a.** PCl_5 **b.** IF_7 **c.** ClF_3 **d.** IO_2

32. **a.** carbon disulfide
b. dichlorine heptoxide
c. CBr_4 **d.** P_2O_3

33. No; the correct name is silicon tetrachloride.

34. Yes; chlorine forms only one bond, and silicon forms four bonds.

35. **a.** molecular; two nonmetals
b. ionic; metal and nonmetal ions
c. ionic; metal and nonmetal ions
d. molecular; two nonmetals

36. BIG IDEA An ionic compound is composed of ions. A molecular compound is composed of molecules.

Extend

Connect to GEOLOGY

Remind students that the Mohs scale rates the hardness of various minerals on a scale of 0 to 10. Discuss that silicon carbide is a binary molecular compound that that has a Mohs scale rating of 9.3. Have students research this compound and what its rating means in terms of its utility in industry.

Evaluate

Informal Assessment

Write each of the following pairs of compounds on an index card.

a. PBr_3 and $CrBr_3$
b. N_2O and Na_2O
c. CI_4 and PbI_4
d. $P_2O_3$and Fe_2O_3

Ask groups of four students to approach your desk. Have each student select one card and identify what the two compounds have in common. *(Each pair has one element in common.)* Then have each student identify which compound in the pair is a binary molecular compound and which one is a binary ionic compound, and name each compound. Then have students complete the 9.3 Lesson Check.

Reteach

Review the guidelines for naming binary molecular compounds. Then, have students write the names of the following compounds: NO, SiO_2, N_2O_4, and ClF_3. *(nitrogen monoxide, silicon dioxide, dinitrogen tetroxide,* and *chlorine trifluoride)* Have students write the formulas for these compounds: arsenic pentachloride, iodine tribromide, and tetraphosphorus hexoxide. *($AsCl_5$, IBr_3,* and *P_4O_6)*

Answers

27. **a.** oxygen difluoride
b. disulfur decafluoride
c. sulfur trioxide
d. sulfur hexafluoride

28. **a.** N_2O_4 **b.** XeF_4 **c.** S_2F_{10} **d.** IF_7

CHEMISTRY & YOU Producers of nutritional supplements are required to list their ingredients in decreasing order by amount on their labels. The ingredients that supply minerals are listed by their chemical names. Because of the cost of redesigning labels, some companies still use common names rather than those based on IUPAC rules. For example, it is not uncommon to see *dibasic calcium phosphate* instead *calcium hydrogen phosphate* listed as a source of calcium and phosphorus. One of the downsides of this continued use of older names is that it is more difficult to write the correct formula for a compound just by looking at its name.

Pose the following question to students: *Why might nutritional supplement companies continue to use non-IUPAC names in their ingredient lists, despite the ease with which IUPAC names can be used to help determine the chemical formula for a compound?* You may need to assist students in the following ways:

- Nutritionists and biochemists tend to be slower to adopt more modern chemical naming conventions than chemists.
- Many older names, such as *dibasic*, convey useful information about a compound's chemical behavior in the body.
- Space on a supplement label is limited. Older name forms are often shorter than those generated using IUPAC naming rules, and thus they take up less space.

Explain

MAKE A CONNECTION Explain that one reason it is important for sports nutrition advisors to understand the "language of chemistry" is that they need to be able to distinguish between good nutritional supplements and supplements that use dangerous ingredients or banned substances. Remind students that many athletic associations ban certain supplement ingredients or other substances because they can give athletes an unfair advantage in a competition. Encourage students who participate in school or extracurricular sporting activities to identify any banned substances in their sport, and explain why the substance has been banned.

Connect to NUTRITION

After reading the passage, instruct students to choose a sport and think about the nutritional requirements of an athlete in that sport. Then have students develop a sample meal plan they feel a nutritionist might recommend to meet those requirements. Encourage students to consider the chemistry of the foods they recommend. For example, students should consider what types of food provide certain vitamins and minerals.

CHEMISTRY & YOU: CAREERS

Sports Nutrition Advisor

Athletes have different nutrition requirements than the average person. As a result, many professional athletes hire nutrition advisors that specialize in athlete nutrition.

Sports nutrition advisors create individualized nutritional programs that ensure optimal body compositions, performance levels, and recovery rates in athletes. The program might include such things as how to maintain energy balance throughout the day, how to avoid dehydration or overhydration, or which vitamins and minerals to take to maintain proper body chemistry.

It is important that the advisors understand the "language of chemistry" to be able to decipher the ingredient labels on products. Registered advisors have taken courses in chemistry, biochemistry, anatomy, physiology, and statistics, in addition to several nutrition classes.

COMPETITIVE IN THE COLD Winter athletes such as snowboarders must maintain their energy stores to train and compete at peak levels.

Take It Further

1. Infer How might understanding chemistry help a sports nutrition advisor develop a personalized meal plan for an athlete?

2. List Choose five nutritional consumer products—food or supplements—from your home. Read the ingredient labels on each product. Make a list of the compounds you understand and classify each as an ionic compound or a molecular compound.

21st Century Learning To be successful in the 21st century, students need skills and learning experiences that extend beyond subject matter mastery. The following project helps students build the following 21st Century Skills: *Creativity and Innovation, Critical Thinking and Problem Solving, Communication and Collaboration, Information Literacy, Initiative and Self-Direction,* and *Productivity and Accountability.*

CHEMISTRY AND FITNESS Pose the following challenge to your students. *The fitness center you work for has asked you to prepare a brochure about the importance of a balanced mineral intake for sports performance.* The brochure should contain the following information:

- The connection between each mineral and body function.
- Photographic examples of foods that contain each mineral, and the chemical formula of the active form of each mineral in the body.
- An explanation of the relationship between adequate mineral intake and sports performance that notes the consequences of mineral deficiencies (e.g., electrolyte imbalances and muscle cramps).

9.4 Naming and Writing Formulas for Acids and Bases

C.3.4 Structural formulas and names

CHEMISTRY & YOU

Q: *What's the name of the acid responsible for the crisp taste in this drink?* There's a certain acid that gives many soft drinks their crisp, enjoyable taste. In this lesson, you will learn the names and formulas of some important acids, including one found in many soft drinks.

Key Questions

- ***How do you determine the name and formula of an acid?***
- ***How do you determine the name and formula of a base?***

Vocabulary

- acid
- base

Names and Formulas of Acids

How do you determine the name and formula of an acid?

Acids are a group of ionic compounds with unique properties. As you will see in Chapter 19, acids can be defined in several ways. For now, it is enough to know that an **acid** is a compound that contains one or more hydrogen atoms and produces hydrogen ions when dissolved in water. Acids have many uses. For example, sulfuric acid is often used to etch circuit boards like the one shown in Figure 9.13.

When naming an acid, you can consider the acid to consist of an anion combined with as many hydrogen ions as needed to make the molecule electrically neutral. Therefore, the chemical formulas of acids are in the general form H_nX, where X is a monatomic or polyatomic anion and n is a subscript indicating the number of hydrogen ions that are combined with the anion.

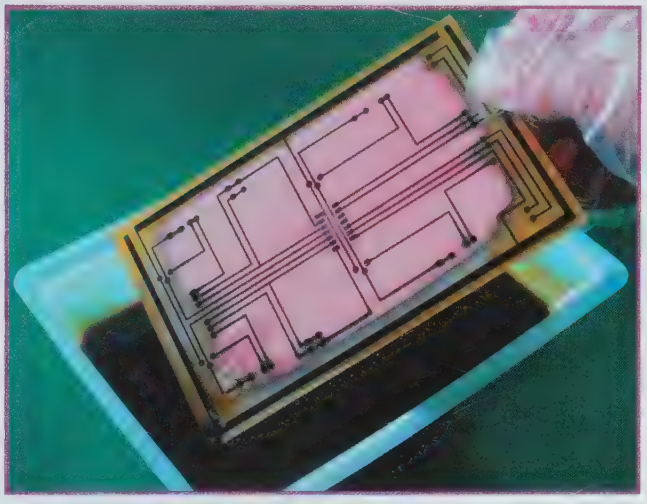

Figure 9.13 Sulfuric Acid
Circuit boards that are used in computers and other electronic devices have grooves (or circuits) that hold the wires for carrying signals. The circuits are often created using a mixture that contains sulfuric acid.

Focus on ELL

1 CONTENT AND LANGUAGE Clarify that the vocabulary word *base* has both common and scientific meanings. Have students brainstorm other applications of this word. Then have students locate the definition of a chemical base in the text. Allow students with limited English to use their native languages for support.

2 FRONTLOAD THE LESSON Have students bring in a favorite family recipe to share with the class. Have students predict which ingredients are acidic in nature and which are basic.

3 COMPREHENSIBLE INPUT Point out that the rules for naming acids are illustrated in Table 9.5, and associate each rule with its row in the table. As a class, work through the Lesson 9.4 Practice Problems.

LESSON 9.4

Key Objectives

9.4.1 DETERMINE the name and formula of an acid.

9.4.2 DETERMINE the name and formula of a base.

Additional Resources

Reading and Study Workbook, Lesson 9.4

Available Online or DVD-ROM:

- Lesson 9.4 Review
- Lesson 9.4 Practice Problems

PearsonChem.com

Engage

CHEMISTRY & YOU Have students examine the labels of several soft drinks and juices. Then, direct students to the text and photograph that opens the lesson. **Ask** How many different acids did you find listed? *(Sample answers: citric acid, ascorbic acid)*Note that some acids are present for reasons other than flavor, such as preservation or, in the case of ascorbic acid (vitamin C), because they are important nutrients.

Activate Prior Knowledge

As a class, create a list of the reagents you have used thus far in the classroom labs. Have students predict which ones are acids and which ones are bases. Students should notice that acids are more easily identified as such because their names contain the word *acid*. Have students copy the list in their notebooks and add any formulas that are encountered during the lesson.

IN ACADEMIC STANDARDS for SCIENCE

C.3.4 Draw structural formulas for and name simple molecules.

Answers

TAKE IT FURTHER

1. A sports nutrition advisor must be able to understand the ingredient list on nutrient labels and how ingested compounds behave inside the client's body.
2. Answers will vary.

Foundations for Reading

BUILD VOCABULARY Make a connection between the scientific and common meanings of the word *acid* by pointing out that a sharp or sour taste is a property of acids. This property can be used to recognize foods, such as lemons, that contain acids. Then, ask students to infer what it might mean to say that a person has "an acid tongue."

READING STRATEGY Encourage students to summarize the rules for naming acids and for naming bases in their own words.

Explain

Names and Formulas of Acids

USE VISUALS Direct students' attention to Table 9.5. Remind students that H^+ is the cation in each acid. It is the anion combined with hydrogen that identifies the acid. Call attention to the first column in which the endings of anions are given. Have students name some anions with the endings *-ide, -ite, and -ate. (Sample answers: chloride, bromide, nitrite, sulfite, carbonate, phosphate)* Call attention to the third column. **Ask** When the anion ends in *-ide*, what does the acid name begin with? *(hydro-)* What does the acid name end with? *(-ic)* **Ask** How would you name an acid containing the bromide anion? *(hydrobromic acid)* Continue the questioning and naming through the other two rows of the table and encourage students to use the table until they are comfortable with naming acids. *(NOTE: In Table 9.6, the formula for ethanoic acid is presented in the HA format: $HC_2H_3O_2$. In Chapter 19, students will be introduced to another way of writing the ethanoic acid formula: CH_3COOH.)*

CHEMISTRY & YOU Phosphoric acid is used in many soft drinks. It provides an acidic, crisp taste.

CRITICAL THINKING Explain that Table 9.5 can also be used to help write formulas for acids, if students use it in reverse. Give students an acid name, for example, perchloric acid. **Ask** What does the *-ic* ending indicate? (*There is no* hydro- *in the name, so* -ic *means the anion ends in* -ate.) **Ask** What is the name and formula for the anion? *(perchlorate, ClO_4)* **Ask** How many hydrogen atoms will combine with the perchlorate ion? *(one, $HClO_4$)*

Continue the questioning until students are comfortable with writing formulas for acids.

Table 9.5

Naming Common Acids

Anion ending	Example	Acid name	Example
-ide	chloride, Cl^-	*hydro-*(stem)*-ic acid*	*hydrochloric acid*
-ite	sulfite, SO_3^-	(stem)*-ous acid*	*sulfurous acid*
-ate	nitrate, NO_3^-	(stem)*-ic acid*	*nitric acid*

CHEMISTRY & YOU

Q: *An acid that provides the crisp taste in many soft drinks has the formula H_3PO_4. What's the name of this acid?*

Three rules can help you name an acid with the general formula H_nX dissolved in water. Read the rules and the examples carefully. Notice that the naming system depends on the name of the anion (X), in particular the suffix of the anion name. Each rule deals with an anion with a different suffix: *-ide*, *-ite*, and *-ate*.

1. **When the name of the anion ends in *-ide*, the acid name begins with the prefix *hydro-*. The stem of the anion has the suffix *-ic* and is followed by the word *acid*.** Therefore, HCl (X = chloride) is named *hydro*chlor*ic acid*.
2. **When the anion name ends in *-ite*, the acid name is the stem of the anion with the suffix *-ous*, followed by the word *acid*.** Thus, H_2SO_3 (X = sulfite) is named sulfur*ous acid*.
3. **When the anion name ends in *-ate*, the acid name is the stem of the anion with the suffix *-ic*, followed by the word *acid*.** Thus, HNO_3 (X = nitrate) is named nitr*ic acid*.

These three rules are summarized in Table 9.5. Use the table to help you write acid names until you become an expert.

Table 9.6

Common Acids

Name	Formula
Hydrochloric acid	HCl
Sulfuric acid	H_2SO_4
Nitric acid	HNO_3
Ethanoic acid	$HC_2H_3O_2$
Phosphoric acid	H_3PO_4
Carbonic acid	H_2CO_3

Writing Formulas of Acids If you know the name of an acid, you can write its formula. **To write the formula for an acid, use the rule for writing the name of the acid in reverse. Then balance the ionic charges just as you would for any ionic compound.** For example, consider hydrobromic acid. Following Rule 1, hydrobromic acid (*hydro-* prefix and *-ic* suffix) must be a combination of hydrogen ion (H^+) and bromide ion (Br^-). So the formula of hydrobromic acid is HBr. How do you write the formula for phosphorous acid? Using Rule 2, hydrogen ion and phosphite ion (PO_3^{3-}) must be the components of phosphorous acid. You need three hydrogen ions to balance the 3– charge of the phosphite anion. Thus, the formula for phosphorous acid is H_3PO_3. Finally, what is the formula for sulfuric acid? According to Rule 3, sulfuric acid (*-ic* ending) must be a combination of hydrogen ion and sulfate ion (SO_4^{2-}). The formula for sulfuric acid is H_2SO_4 because two hydrogen ions are needed to balance the 2– charge of the sulfate anion.

Many industrial processes, including steel and fertilizer manufacturing, use acids. You should become familiar with the names and formulas of common acids such as those listed in Table 9.6.

Professional Development Note

Acid Preservatives Many food labels mention parenthetically that an acid has been added as a preservative. The use of acids as a preservative goes back about 5,000 years, with the discovery that vinegars had a preservative effect on foods. Vinegars, which contain acetic acid, are still used today to preserve cucumbers and other vegetables in a process known as pickling. Other vegetables, and even some livestock feeds, are preserved with the lactic acid from bacterial fermentation within the food itself. Even though the acids differ from one application to the next, they all exert their preservative actions in the same manner—their low pH inhibits the growth of destructive bacteria and fungi in the preserved foods within the anaerobic environment of a sealed jar or silo.

SampleProblem 9.8

Naming Acids

Name the following compounds as acids:

a. HClO **b.** HCN

1 Analyze **Identify the relevant concepts.** The anion of the acid determines the acid name. (1) If the name of the anion ends in *-ide*, name the acid using the stem of the anion with the prefix *hydro-* and the suffix *-ic*, followed by the word *acid*. (2) If the anion name ends in *-ite*, name the acid using the stem of the anion with the suffix *-ous*, followed by the word *acid*. (3) If the anion name ends in *-ate*, name the acid using the stem of the anion with the suffix *-ic*, followed by the word *acid*.

2 Solve **Apply the concepts to this problem.**

	a.	**b.**
Identify the anion in the acid and the suffix of the anion name.	ClO^- (*hypochlorite*)	CN^- (*cyanide*)
Name the acid using the appropriate prefix (if any) and suffix. Finish with the word *acid*.	hypochlorous acid (Rule 2)	hydrocyanic acid (Rule 1)

37. Name the following compounds as acids:
- **a.** HF
- **b.** HNO_3
- **c.** H_2SO_3

38. Write formulas for the following acids:
- **a.** perchloric acid
- **b.** hydroiodic acid
- **c.** chlorous acid

Hint: For Problem 38, use the corresponding naming rule in reverse.

Names and Formulas of Bases

How do you determine the name and formula of a base?

A **base** is generally an ionic compound that produces hydroxide ions when dissolved in water. **Bases are named in the same way as other ionic compounds—the name of the cation is followed by the name of the anion.** The common base sodium hydroxide is used in making cleaners, soap, and paper as shown in Figure 9.14. Sodium hydroxide (NaOH) is composed of sodium cations (Na^+) and hydroxide anions (OH^-).

To write the formula for a base, first write the symbol for the metal cation followed by the formula for the hydroxide ion. Then, balance the ionic charges just as you would for any ionic compound. For example, aluminum hydroxide consists of the aluminum cation (Al^{3+}) and the hydroxide anion (OH^-). You need three hydroxide ions to balance the 3+ charge of the aluminum cation. Thus, the formula for aluminum hydroxide is $Al(OH)_3$.

Figure 9.14 Use of Sodium Hydroxide
In the first step of papermaking, manufacturers use NaOH to break down recycled paper and wood to make pulp.

Differentiated Instruction

L1 STRUGGLING STUDENTS Create a set of flash cards by writing the formula for an acid or base on one side of an index card and its name on the other. Alternate showing formulas and names to the class. Have students supply the missing name or formula for each card shown.

ELL ENGLISH LANGUAGE LEARNERS Beginning students may have difficulty distinguishing and pronouncing the different endings for acids, bases, and their associated ions. Write each on the board and pronounce slowly and clearly. Have students practice saying the names to become familiar with their pronunciations.

L3 ADVANCED STUDENTS Have students research the meaning of pH and how it relates to acids and bases. Then have students explain their findings by displaying and classifying common household products such as coffee, antacids, drain cleaner, apple juice, and so on from most acidic to least acidic. Have students explain that least acidic means most basic and define what is meant by neutral on the pH scale.

Explain

USE VISUALS Have students examine the common acids in Table 9.6. Have students match up each of these acids with one of the three rules explained under Table 9.5. Encourage students to recreate the table in their notebooks and add helpful information to it as needed.

MAKE A CONNECTION Refer students to Table 9.3, Common Polyatomic Ions, in Lesson 9.1. Discuss how to rewrite each of these ions as an acid. Work through the entire table or until students become comfortable with the process.

Sample Practice Problem

Identify which compound is an acid: HOCl, K_2O, or NaOH. Then, name the acid. *(HOCl; hypochlorous acid)*

Names and Formulas of Bases

MAKING CONNECTIONS Direct students to Lesson 9.2 and review the guidelines for naming and writing ionic compounds. Use the flowchart from that lesson, or create a new one for this lesson, for students to follow for naming a base, or for writing a formula for a base. **Ask** What ion is typically seen in the formula for all bases? *(hydroxide ion)* **Ask** What is the charge on this ion? *(1–)*

Answers

37. **a.** hydrofluoric acid **b.** nitric acid **c.** sulfurous acid

38. **a.** $HClO_4$ **b.** HI **c.** $HClO_2$

Extend

Connect to APPLIED CHEMISTRY

Explain to the class that sodium hydroxide is a powerful base. Have students research and find at least five different industrial uses of sodium hydroxide. Tell students to explain why this particular base is used for each given application, the concentration of base used, and the appropriate Material Data Safety Sheet (MSDS) for the base at that specific concentration.

Sample Practice Problem

Which of the following is a base? Name the base.

H_2S, CsOH, $FeCl_2$ *(CsOH, cesium hydroxide)*

Evaluate

Informal Assessment

Present only the names of the six common acids in Table 9.6 and a copy of Table 9.5. Have students name the anion and write the formulas for each acid. Ask students to write a statement explaining how to determine whether the compound is a base. Then have students complete the 9.4 Lesson Check.

Reteach

Review with students the rules for writing and naming acids and bases. Create a chart comparing and contrasting the two methods. Then, have students complete the assessment again.

SampleProblem 9.9

Naming Bases

Name the following bases:

a. KOH **b.** $Fe(OH)_2$

1 Analyze **Identify the relevant concepts.** Bases are named like other ionic compounds—the name of the cation is followed by the name of the anion.

2 Solve **Apply the concepts to this problem.**

First identify the cation and the anion in the compound.

a. cation: K^+
anion: OH^-

b. cation: Fe^{2+}
anion: OH^-

Now write the name of the cation, followed by the name of the anion.

potassium hydroxide

iron(II) hydroxide

Remember: You need to include a Roman numeral if the metal ion can have different ionic charges.

39. Name the following bases:
- **a.** $Ba(OH)_2$
- **b.** $Ca(OH)_2$
- **c.** RbOH

40. Write formulas for the following bases:
- **a.** cesium hydroxide
- **b.** beryllium hydroxide
- **c.** manganese(III) hydroxide

9.4 LessonCheck

41. Review Explain how to determine the name and formula of an acid.

42. Review How are the names and formulas determined for bases?

43. Identify Give the names of the following acids:
- **a.** HNO_2
- **b.** $HMnO_4$
- **c.** HBr
- **d.** H_2S

44. Identify Write the names of these bases.
- **a.** LiOH
- **b.** $Pb(OH)_2$
- **c.** $Mg(OH)_2$
- **d.** $Al(OH)_3$

45. Classify Identify each compound as an acid or a base. Then name each compound.
- **a.** NH_4OH
- **b.** $HClO_3$
- **c.** $Fe(OH)_3$
- **d.** KOH

46. Describe Write the formulas for these ionic compounds.
- **a.** carbonic acid
- **b.** sulfurous acid
- **c.** iron(III) hydroxide
- **d.** zinc hydroxide

47. Compare What element generally appears in the formula of an acid? What ion generally appears in the formula of a base?

Lesson Check Answers

41. See the rules for naming acids on page 286. Use the rules for naming acids in reverse to write the formula.

42. The name of the cation is followed by the name of the anion. To write the formula, write the symbol for the cation then the formula for the anion. Then, balance the charges.

43. **a.** nitrous acid
b. permanganic acid
c. hydrobromic acid
d. hydrosulfuric acid

44. **a.** lithium hydroxide
b. lead(II) hydroxide
c. magnesium hydroxide
d. aluminum hydroxide

45. **a.** base, ammonium hydroxide
b. acid, chloric acid
c. base, iron(III) hydroxide
d. base, potassium hydroxide

46. **a.** H_2CO_3 **b.** H_2SO_3
c. $Fe(OH)_3$ **d.** $Zn(OH)_2$

47. acid, hydrogen; base, hydroxide ion

9.5 The Laws Governing How Compounds Form

C.3.4 Structural formulas and names

CHEMISTRY & YOU

Q: *Did you know that sand from a beach can be used to make glass?* Sand contains the compound silicon dioxide, which is used in glass making. One molecule of silicon dioxide consists of one silicon atom and two oxygen atoms. In this lesson, you will learn why the ratio of silicon to oxygen atoms in silicon dioxide is always the same.

Key Questions

- *How is the law of definite proportions consistent with Dalton's atomic theory?*
- *What general guidelines can help you write the name and formula of a chemical compound?*

Vocabulary

- law of definite proportions
- law of multiple proportions

The Laws of Definite and Multiple Proportions

How is the law of definite proportions consistent with Dalton's atomic theory?

Consider the compound calcium carbonate ($CaCO_3$), which is commonly found in rocks. Whether you find the compound in a rock in Thailand or New Zealand, it is still calcium carbonate. This statement is true because the three elements—calcium, carbon, and oxygen—are combined in the same proportions in every molecule of $CaCO_3$. Two laws—the law of definite proportions and the law of multiple proportions—describe the proportions in which elements combine to form compounds. The rules for naming and writing formulas for compounds are possible because compounds obey these two rules.

Law of Definite Proportions A chemical formula tells you, by means of subscripts, the ratio of atoms of each element in the compound. Ratios of atoms can also be expressed as ratios of masses. For example, magnesium sulfide (MgS) is composed of magnesium cations and sulfide anions. If you could take 100.00 g of magnesium sulfide and break it down into its elements, you would obtain 43.13 g of magnesium and 56.87 g of sulfur. The Mg:S ratio of these masses is 43.13/56.87 or 0.758:1. This mass ratio does not change regardless of how the magnesium sulfide is formed or the size of the sample. Magnesium sulfide obeys the **law of definite proportions,** which states that in samples of any chemical compound, the masses of the elements are always in the same proportions. This law is consistent with Dalton's atomic theory.

Dalton postulated that atoms combine in simple whole-number ratios. If the ratio of atoms of each element in a compound is fixed, then it follows that the ratio of their masses is also fixed.

Focus on ELL

1 CONTENT AND LANGUAGE Review mathematical vocabulary such as *ratio*, *proportion*, and *multiple*. Divide students into three small groups. Assign each group one term. Have each group define its term, give an example and a non-example, and present it to the class.

2 FRONTLOAD THE LESSON Discuss the difference between a *law* in science and a *law* in society. Use a Venn diagram to help students see the similarities and the differences.

3 COMPREHENSIBLE INPUT For Figure 9.16, point out the mathematical operators in each graph. Clarify for students that the masses of compounds *X* and *Y* are equal to the sums of the elements *A* and *B* in the two graphs. Make sure that students understand how to use the "yes" and "no" options in Figures 9.18 and 9.19 to navigate through each flowchart.

Key Objectives

9.5.1 EXPLAIN how the law of definite proportions is consistent with Dalton's atomic theory.

9.5.2 LIST the general guidelines that can help you write the name and formula of a chemical compound.

Additional Resources

Reading and Study Workbook, Lesson 9.5

Available Online or DVD-ROM:

- Lesson 9.5 Review

PearsonChem.com

Engage

Activate Prior Knowledge

Ask a student volunteer to explain what a proportion means mathematically. Make sure that students understand that a proportion is an equation stating that two ratios are equal. Review how to use cross products to solve for an unknown quantity in a proportion.

Foundations for Reading

BUILD VOCABULARY A scientific law is a statement of a relationship that is unchanging so far as it is known. Thus, the law of definite proportions and the law of multiple proportions are unchanging, or constant, statements governing the formation of compounds.

READING STRATEGY As you familiarize students with the flowcharts in Figures 9.18 and 9.19, verbalize the routes to a name or formula by asking and answering the questions posed at each intersection.

IN ACADEMIC STANDARDS for SCIENCE

C.3.4 Draw structural formulas for and name simple molecules.

Answers

39. **a.** barium hydroxide
b. calcium hydroxide
c. rubidium hydroxide

40. **a.** CsOH **b.** $Be(OH)_2$ **c.** $Mn(OH)_3$

Explain

The Laws of Definite and Multiple Proportions

USE MODELS Direct students' attention to Figure 9.15. Ask students to use the space-filling models to determine the formulas for the two compounds. *(CuCl and $CuCl_2$)* **Ask** In what other way can you tell that the two compounds are different? *(One is green, and the other is blue.)*

APPLY CONCEPTS Students may be able to understand the law of multiple proportions more easily by thinking in terms of atoms. Explain that one atom of carbon in CO_2 has the same mass (12 amu) as one atom of carbon in CO. One atom of oxygen (16 amu) combines with 12 amu of carbon in CO. Two atoms of oxygen (32 amu) combine with 12 amu of carbon in CO_2. The ratio of the masses of oxygen in the two compounds is 32:16 or 2:1. Explain to students that ratios are typically written in one of three ways—as a fraction, as a statement separated by colons, and as a statement separated by the word *to*.

Law of Multiple Proportions In the early 1800s, Dalton and others studied pairs of compounds that contain the same elements but have different physical and chemical properties. Using the results from these studies, Dalton stated the **law of multiple proportions:** Whenever the same two elements form more than one compound, the different masses of one element that combine with the same mass of the other element are in the ratio of small whole numbers. Figure 9.15 shows two compounds—CuCl and $CuCl_2$—that demonstrate the law of multiple proportions.

Figure 9.15 CuCl and $CuCl_2$
a. Copper(I) chloride (CuCl) contains the elements copper and chlorine. This compound is green. **b.** Copper(II) chloride ($CuCl_2$) contains the same two elements as copper(I) chloride—copper and chlorine. But, this compound is blue.

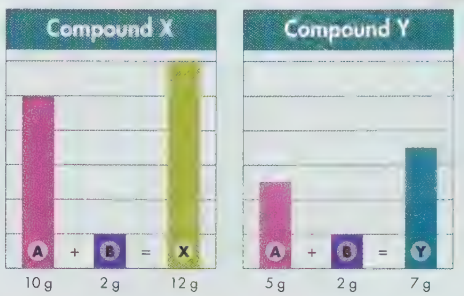

Figure 9.16 Law of Multiple Proportions
Two compounds, X and Y, contain equal masses of element B. The ratio of the masses of A in these compounds is 10:5 or 2:1 (a small whole-number ratio).
Compare ***Would the ratio be different if samples of X and Y contained 3 g of B? Explain.***

Two familiar compounds, water (H_2O) and hydrogen peroxide (H_2O_2), are formed by the same two elements. Although these compounds are formed by the elements hydrogen and oxygen, they have different physical and chemical properties. For example, water does not bleach fabric dyes, but hydrogen peroxide bleaches the dye in most fabrics. Each compound obeys the law of definite proportions. In every sample of hydrogen peroxide, 16.0 g of oxygen are present for each 1.0 g of hydrogen. The mass ratio of oxygen to hydrogen is always 16:1. In every sample of water, the mass ratio of oxygen to hydrogen is always 8:1. If a sample of hydrogen peroxide has the same mass of hydrogen as a sample of water, the ratio of the mass of oxygen in the two compounds is exactly 2:1.

$$\frac{16 \text{ g O (in } H_2O_2 \text{ sample that has 1 g H)}}{8 \text{ g O (in } H_2O \text{ sample that has 1 g H)}} = \frac{16}{8} = \frac{2}{1} = 2:1$$

A simple example of the law of multiple proportions is shown in Figure 9.16.

Proust's Law

In the early 1800s, many scientists were studying chemical reactions by carefully measuring the masses of reactants and products. The French scientist Joseph Proust (1766–1844) demonstrated that samples of copper carbonate always contain 5.3 parts by mass of copper to 4 parts of oxygen and 1 part of carbon. The principle embodied in this discovery became known as Proust's Law and later as the law of definite proportions. Proust's experiments inspired John Dalton to think in terms of atoms. With atoms in mind, Dalton designed experiments that soon led to the law of multiple proportions and Dalton's atomic theory.

Sample Problem 9.10

Calculating Mass Ratios

Carbon reacts with oxygen to form two compounds. Compound A contains 2.41 g of carbon for each 3.22 g of oxygen. Compound B contains 6.71 g of carbon for each 17.9 g of oxygen. What is the lowest whole-number mass ratio of carbon that combines with a given mass of oxygen?

1 Analyze List the knowns and the unknown.
Apply the law of multiple proportions to the two compounds. For each compound, find the grams of carbon that combine with 1.00 g of oxygen. Then find the ratio of the masses of carbon in the two compounds. Confirm that the ratio is the lowest whole-number ratio.

KNOWNS
Compound A = 2.41 g C and 3.22 g O
Compound B = 6.71 g C and 17.9 g O

UNKNOWN
Mass ratio of C per g O in the two compounds = ?

2 Calculate Solve for the unknown.

First, calculate grams of carbon per gram of oxygen in compound A.

$$\frac{2.41\ g\ C}{3.22\ g\ O} = \frac{0.748\ g\ C}{1.00\ g\ O}$$

Then, calculate grams of carbon per gram of oxygen in compound B.

$$\frac{6.71\ g\ C}{17.9\ g\ O} = \frac{0.375\ g\ C}{1.00\ g\ O}$$

To calculate the mass ratio, compare the masses of one element per one gram of the other element in each compound.

Calculate the mass ratio to compare the two compounds.

$$\frac{0.748\ g\ C}{0.375\ g\ C} = \frac{1.99}{1} \approx \frac{2}{1}$$

Express the mass ratio as the lowest whole-number ratio.

The mass ratio of carbon per gram of oxygen in the two compounds is 2:1.

3 Evaluate Does this result make sense? The ratio is a low whole-number ratio, as expected. For a given mass of oxygen, compound A contains twice the mass of carbon as compound B.

48. Lead forms two compounds with oxygen. One contains 2.98 g of lead and 0.461 g of oxygen. The other contains 9.89 g of lead and 0.763 g of oxygen. For a given mass of oxygen, what is the lowest whole-number mass ratio of lead in the two compounds?

49. In the compound iron(III) oxide, also known as rust, the mass ratio of iron to oxygen is 7:3. A 33-g sample of a compound composed of iron and oxygen contains 10 g of oxygen. Is the sample iron(III) oxide? Explain.

To answer Problem 49, first calculate the mass of iron in the sample.

Foundations for Math

RATIOS In mathematics, a ratio expresses the magnitude of two quantities relative to each other. Ratios can be expressed in multiple forms: $\frac{a}{b}$, *a* to *b*, or *a*:*b*. When a ratio is in the form $\frac{a}{b}$, it is clear that it is a quotient and can be simplified using division.

In **Sample Problem 9.10,** the grams of carbon per gram of oxygen in compound A $\left(\frac{2.41\ g\ C}{3.22\ g\ O}\right)$ can be found using division: 2.41 ÷ 3.22 = 0.748, which can be written as $\frac{0.748\ g\ C}{1.00\ g\ O}$. For this calculation, the format $\frac{a}{b}$ is more convenient. However, when writing the final mass ratio, the format *a*:*b* is typically used because the law of multiple proportions states that the masses will always be in small whole-number ratios.

LESSON 9.5

Explain

USE VISUALS Have students examine Figure 9.16. **Ask** How many grams of *B* are in compound *X*? *(2 g)* **Ask** How many grams of *B* are in compound *Y*? *(2 g)* State that the two compounds have the same masses of *B*. **Ask** What is the ratio between the masses of *A* in these two compounds that have equal masses of *B*? *(10 g:5 g or 2:1)* **Ask** Name the law illustrated by the figure and define it in your own words. *(Sample answer: The law of multiple proportions; When two compounds are formed from the same two elements, and you take a certain mass of one of the elements, the masses of the other element in the two compounds that combined with that certain mass of the first element are in a whole-number ratio).*

Sample Practice Problem

Phosphorus forms two compounds with oxygen. A 3.00 gram sample of Compound *A* contains 1.69 g of phosphorus and 1.31 g of oxygen, while a 5.00 gram sample of Compound *B* contains 2.18 grams phosphorus and 2.82 g of oxygen. For a given mass of oxygen, calculate the lowest whole-number mass ratio of phosphorus in the two compounds.

(1.66:1 ≈ 5:3)

Answers

FIGURE 9.16 No, as long as the two samples have the same mass of *B*.

48. 1:2

49. Yes, because the ratio in the compound is 2.3:1 and the ratio in iron(III) oxide is 2.3:1.

Explain

Practicing Skills: Chemical Names and Formulas

START A CONVERSATION To emphasize the importance of having a consistent method for naming chemical compounds, ask questions that students can relate to in their daily lives. **Ask** Name some situations in which specific names are important for accurate or fast results. *(when you are ordering items by telephone or on the Internet)* **Ask** Why do many bureaucratic agencies use social security or driver's license numbers instead of people's names? *(Many people could have the same name.)*

DRAW CONCLUSIONS Direct students to the opening paragraph on this page. Discuss the importance of naming conventions for compounds. Explain that chemists need to be able to understand papers written by colleagues and to reproduce experimental results. Focus on the problems that could occur if common names in multiple languages were the norm. **Ask** Why would knowing the correct name for a chemical be important to a poison-control center worker? *(The worker needs to know the specific chemical ingested before offering a solution. Administering an antidote for the wrong chemical could cause further harm.)*

Figure 9.17 Petrified Wood When wood ages, certain compounds from the sediment can replace the dead tissue in the wood. The process is called petrification. Some of these compounds are colored and provide the various colors in the petrified wood.

Practicing Skills: Chemical Names and Formulas

What general guidelines can help you write the name and formula of a chemical compound?

In the average home, you can probably find hundreds of chemicals, including cleaning products, pharmaceuticals, and pesticides. You've probably noticed warning labels on products, which tell about their possible dangers. Most people would not know what to do if a child ingested one of these chemicals. A phone call to a poison control center can provide lifesaving information to victims of such poisonings. But a poison control center can be much more effective if the caller can supply some information about the name or formula of the substance.

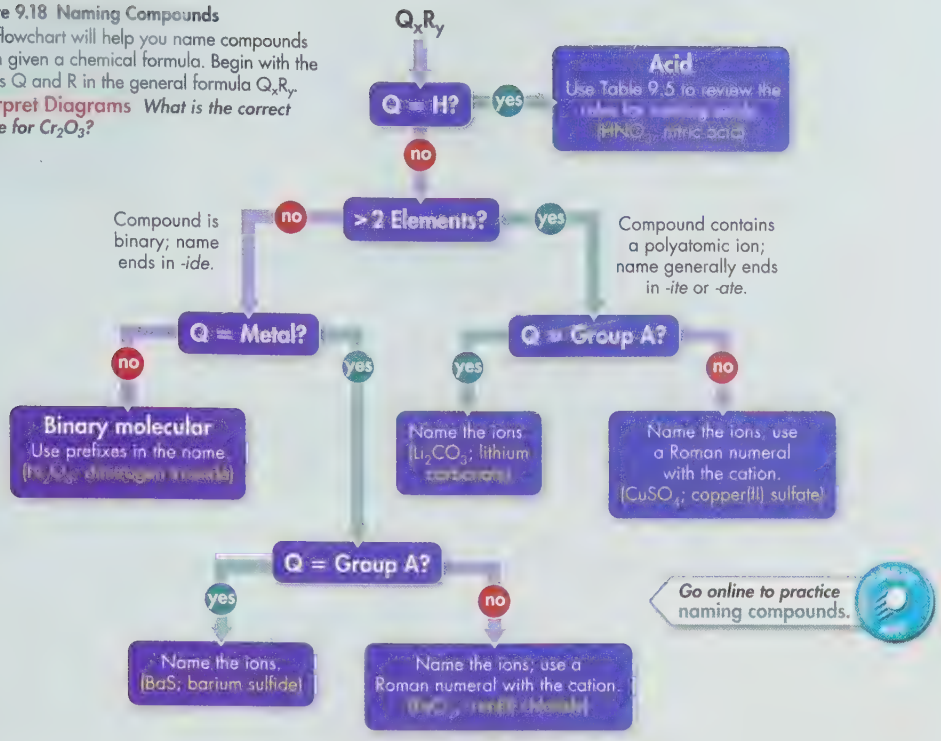
Naming Chemical Compounds One of the skills you learned in this chapter is to name chemical compounds. If this is the first time you have tried to master this skill, you may feel a little overwhelmed. For example, you may find it difficult to know when you should or should not use prefixes and Roman numerals in a name. Or you may have trouble determining if a compound's name should end in *-ate, -ide,* or *-ite.*

Here are some guidelines to help you in naming a chemical compound from the chemical formula.

1. **Follow the rules for naming acids when H is the first element in the formula.**
2. **If the compound is binary, generally the name ends with the suffix *-ide*. If the compound is a molecular binary compound, use prefixes to indicate the number of atoms.**
3. **When a polyatomic ion that includes oxygen is in the formula, the compound name generally ends in *-ite* or *-ate*.**
4. **If the compound contains a metallic cation that can have different ionic charges, use a Roman numeral to indicate the numerical value of the ionic charge in the compound.**

The flowchart in Figure 9.18 provides you with a sequence of questions for naming a compound when you know its formula. Follow the arrows and answer the questions on the flowchart to write the correct name for a compound. The sequence of questions in the flowchart can help you name compounds you may have in your home as well as the compounds that are responsible for the beautiful colors in the petrified wood shown in Figure 9.17. Apply the general formula Q_xR_y to each compound. Q and R can be atoms, monatomic ions, or polyatomic ions. For example, to name HNO_3, let H = Q and NO_3 = R. Follow the first arrow down to the question "Q = H?" The answer is yes, so the arrow to the right tells you that the compound is an acid. You can then follow the rules for naming acids. HNO_3 is nitric acid.

To name the compound N_2O_3, let N = Q and O = R. The answer to the question "Q = H?" is no, so you follow the arrow down. Does the compound have more than two elements? The answer is no, so you follow the arrow to the left. The compound is binary, and its name ends in *-ide*. Is Q a metal? The answer is no, so you must use prefixes in the name for N_2O_3, which is *di*nitrogen *tri*oxide. Practice naming other compounds using the flowchart. Soon you won't need the flowchart anymore.



Differentiated Instruction

L1 STRUGGLING STUDENTS Students who have difficulty with mathematics may need extra help with the laws of definite proportions and the law of multiple proportions. Assign such students to work with students with strong math skills. Encourage students with strong math skills to develop ways of sharing their problem-solving techniques with others.

LPR LESS PROFICIENT READERS Have students compare Figure 9.18 to the rules in the text on page 292, and Figure 9.19 to the rules on page 293. Give students copies of the two figures and encourage them to write the number of each rule next to the point in the flowchart where it is applied.

L3 ADVANCED STUDENTS Challenge advanced students to use the flowchart as a model for writing a computer program for naming chemical compounds.

Figure 9.18 Naming Compounds
This flowchart will help you name compounds when given a chemical formula. Begin with the letters Q and R in the general formula Q_xR_y.
Interpret Diagrams *What is the correct name for Cr_2O_3?*

Writing Chemical Formulas In writing a chemical formula from a chemical name, it is helpful to remember the following guidelines:

1. **An *-ide* ending generally indicates a binary compound.**
2. **An *-ite* or *-ate* ending means a polyatomic ion that includes oxygen is in the formula.**
3. **Prefixes in a name generally indicate that the compound is molecular.**
4. **A Roman numeral after the name of a cation shows the ionic charge of the cation.**

These guidelines and the questions in the flowchart in Figure 9.19 will help you write the formula for a compound when you know its name. For example, use the flowchart to write the formula for sodium chromate. The name does not contain prefixes, so the compound is ionic. The ions are sodium ion and chromate ion. Sodium is a Group A element, so use the periodic table or Table 9.1 to obtain its ionic charge (1+). Chromate ion is a polyatomic ion, so use Table 9.3 to obtain its charge (2−). Balance the charges to obtain the formula Na_2CrO_4. Use this flowchart to practice writing formulas until you don't need it anymore.

CHEMISTRY & YOU

Q: *Use the flowchart in Figure 9.19 to help you write the formula for silicon dioxide.*

Focus on ELL

4 LANGUAGE PRODUCTION Have students work in groups of four to complete the lab on page 295. Make sure each group has ELLs of varied language proficiencies, so that more proficient students can help less proficient ones. Have students work according to their proficiency level.

BEGINNING: LOW/HIGH Provide the grid for students and model how to complete the reactions using the first square.

INTERMEDIATE: LOW/HIGH Paraphrase the procedure and Analyze and Conclude questions for students.

ADVANCED: LOW/HIGH Have students assist those of lower English proficiencies with the procedure and with answering the questions.

Explain

USE VISUALS Tell students to study Figure 9.18. Point out that the flowchart is like a road map. At every intersection you need to make a decision, and when you make the right decisions you are led to your destination (the correct name for the compound). Lead them through a few examples asking them to respond to the questions at each intersection. Then, have volunteers take the lead to continue the exercise.

MAKE A CONNECTION While students are involved in developing their skills in determining names and writing formulas for ionic and molecular compounds, you may have the opportunity to comment on the characteristics of representative ionic and molecular compounds found in Figure 9.18. For example, call attention to the high melting points of ionic compounds. Iron(II) chloride melts at 677°C; lithium carbonate, at 723°C. In addition, a large amount of energy (heat of fusion) is required to melt these ionic compounds. By contrast, the molecular compound dinitrogen trioxide melts at 101°C, and methane melts at 182°C. Emphasize that the ionic and molecular compounds do not differ just in the way that they are named but fundamentally in the bonding that holds the atoms together in the compound.

CHEMISTRY & YOU The formula for silicon dioxide is SiO_2.

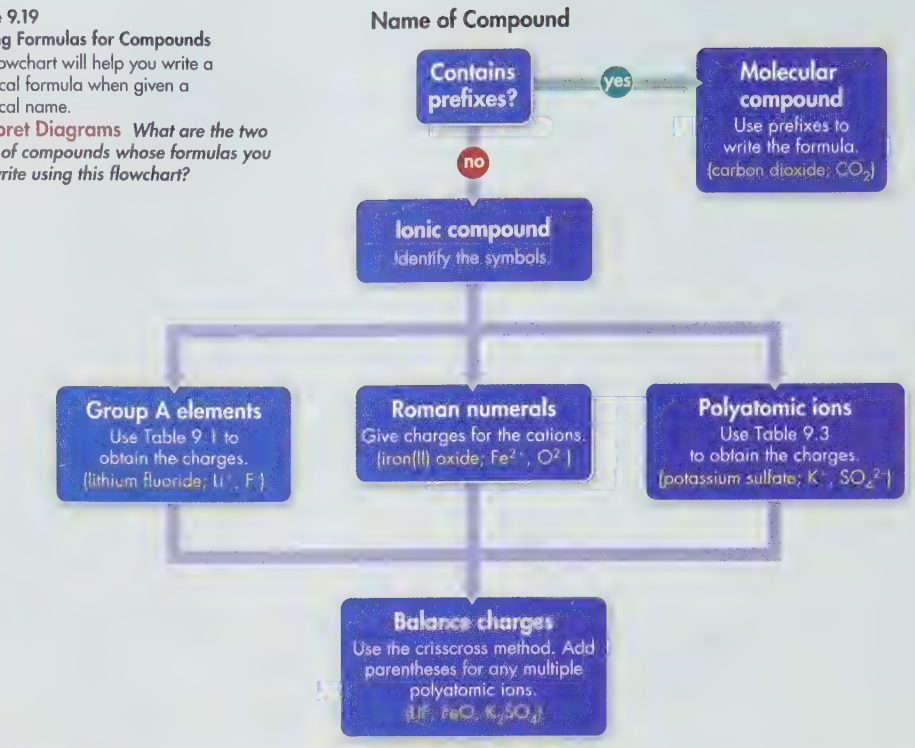
Answers

FIGURE 9.18 chromium(III) oxide

Explain

SUMMARIZE Have students summarize the rules for writing formulas and naming compounds. Point out that naming compounds and writing formulas becomes easier with practice because chemical names and formulas are systematized. Ask students to consider how difficult the task would be if the names were assigned randomly. Because chemists adhere to an established system of naming, it is possible to quickly locate information on physical constants such as melting point, boiling point, and density in chemical handbooks such *Lange's Handbook of Chemistry, The Merck Index,* and the *CRC Handbook of Chemistry and Physics*. *The Merck Index* is particularly helpful to organic chemists interested in the synthesis and identification of a particular compound. Encourage students to look for these books in their local public library.

Evaluate



Informal Assessment

Ask students to explain what it means when each of the following is included in the name of a compound: an *-ide* ending, an *-ite* or *-ate* ending, a prefix, or a Roman numeral. Then, give students the following names of compounds containing one of these components: hydrogen cyanide, potassium chromate, sulfur tetrafluoride, or copper(I) chloride. Allow students to use Figure 9.19 to determine the corresponding formula. Then have students complete the 9.5 Lesson Check.

Reteach

For students struggling with the assessment, review the four skills for writing names and chemical formulas. Paraphrase each rule so students can clearly understand what is being stated. Work alongside students by stating various compounds and seeing whether students can adequately use Figure 9.18 to determine the names. Then, give them names for different compounds and check whether they can adequately use Figure 9.19 to write the corresponding formulas.

Figure 9.19
Writing Formulas for Compounds
This flowchart will help you write a chemical formula when given a chemical name.
Interpret Diagrams *What are the two types of compounds whose formulas you can write using this flowchart?*

9.5 LessonCheck

50. **Review** How is the law of definite proportions consistent with Dalton's atomic theory?

51. **List** What general guidelines can help you write the name and formula of a compound?

52. **Compare** Two compounds that contain copper and chlorine have the following masses:

Compound A: 32.10 g Cu and 17.90 g Cl
Compound B: 23.64 g Cu and 26.37 g Cl

Are the compounds the same? If not, what is the lowest whole-number mass ratio of copper that combines with a given mass of chlorine?

53. **Identify** Name the following compounds:
a. $CaCO_3$ **b.** $PbCrO_4$ **c.** $SnCr_2O_7$

54. **Describe** Write the chemical formulas for each of the following compounds:
a. tin(II) hydroxide **c.** tetraiodide nonoxide
b. barium fluoride **b.** iron(III) oxalate

55. **Evaluate** Identify any incorrect names or formulas from the following choices. Explain your answer(s).
a. calcium(II) oxide **c.** $Na_2C_2O_4$
b. aluminum oxide **d.** $Mg(NH_4)_2$

BIGIDEA BONDING AND INTERACTIONS

56. Explain why the chemical composition of water (H_2O) is always the same.

Lesson Check Answers

50. Dalton postulated that atoms combine in simple whole-number ratios. If the ratio of atoms of each element in a compound is fixed, then it follows that the ratio of their masses is also fixed.

51. Refer to the rules listed on pages 292 and 293.

52. no; 2:1

53. **a.** calcium carbonate
b. lead(II) chromate
c. tin(II) dichromate

54. **a.** $Sn(OH)_2$ **b.** BaF_2 **c.** I_4O_9
d. $Fe_2(C_2O_4)_3$

55. **a.** incorrect; a Roman numeral is not used with a Group A metal, calcium oxide
d. Incorrect; ammonium ion, a polyatomic cation, will not form a compound with a monatomic cation.

56. **BIG**IDEA As stated in the law of definite proportions, the masses of the elements in H_2O, hydrogen and oxygen, are always in the same proportion, 2:1.

Small-Scale Lab

Names and Formulas for Ionic Compounds

Purpose

To observe the formation of compounds and to write their names and formulas

Materials

- pencil
- paper
- ruler
- reaction surface
- chemicals shown in Figure A
- chemicals shown in Figure B

Procedure

On separate sheets of paper, draw two grids similar to Figure A. Make each square 2 cm on each side. Draw black X's on one of the grids. Use the other grid as a data table to record your observations. Place a reaction surface over the grid with black X's and add the chemicals as indicated in Figure A.

	$AgNO_3$ (Ag^+)	$Pb(NO_3)_2$ (Pb^{2+})	$CaCl_2$ (Ca^{2+})
Na_2CO_3 (CO_3^{2-})	a	e	i
Na_3PO_4 (PO_4^{3-})	b	f	j
NaOH (OH^-)	c	g	k
Na_2SO_4 (SO_4^{2-})	d	h	l

Figure A

	$FeCl_3$ (Fe^{3+})	$MgSO_4$ (Mg^{2+})	$CuSO_4$ (Cu^{2+})
Na_2CO_3 (CO_3^{2-})	a	e	i
Na_3PO_4 (PO_4^{3-})	b	f	j
NaOH (OH^-)	c	g	k
Na_2SO_4 (SO_4^{2-})	d	h	l

Figure B

Analyze and Conclude

1. Observe Describe each precipitate (solid product) that forms. Use terms such as *milky, grainy, cloudy,* or *gelatinous.* Which mixture(s) did not form a precipitate?

2. Describe Write the formulas and names of the chemical compounds produced in the mixings.

You're the Chemist

1. Analyze Data Repeat the experiment, using the chemicals in Figure B. Identify the precipitates, write their formulas, and name them.

2. Explain In ionic equations, the precipitate is written to the right of an arrow, and the ions that produced it are written to the left. Write ionic equations for the precipitates formed from the reactions related to Figure B. For example, the first reaction in Figure B would be written as follows:

$$2Fe^{3+} + 3CO_3^{2-} \longrightarrow Fe_2(CO_3)_3$$

YOU'RE THE CHEMIST

1. **a.** $Fe_2(CO_3)_3$ iron(III) carbonate
   b. $FePO_4$, iron(III) phosphate
   c. $Fe(OH)_3$, iron(III) hydroxide
   e. $MgCO_3$, magnesium carbonate
   f. $Mg_3(PO_4)_2$, magnesium phosphate
   g. $Mg(OH)_2$, magnesium hydroxide
   i. $CuCO_3$, copper(II) carbonate
   j. $Cu_3(PO_4)_2$, copper(II) phosphate
   k. $Cu(OH)_2$, copper(II) hydroxide

2. **a.** $2Fe^{3+} + 3CO_3^{2-} \rightarrow Fe_2(CO_3)_3(s)$
   b. $Fe^{3+} + PO_4^{3-} \rightarrow FePO_4(s)$
   c. $Fe^{3+} + 3OH^- \rightarrow Fe(OH)_3(s)$
   e. $Mg^{2+} + CO_3^{2-} \rightarrow MgCO_3(s)$
   f. $3Mg^{2+} + 2PO_4^{3-} \rightarrow Mg_3(PO_4)_2(s)$
   g. $Mg^{2+} + 2OH^- \rightarrow Mg(OH)_2(s)$
   i. $Cu^{2+} + CO_3^{2-} \rightarrow CuCO_3(s)$
   j. $3Cu^{2+} + 2PO_4^{3-} \rightarrow Cu_3(PO_4)_2(s)$
   k. $Cu^{2+} + 2OH^- \rightarrow Cu(OH)_2(s)$

FOR ENRICHMENT Have students design an experiment to make a measureable amount of a precipitate, separate it, dry it, and determine its mass.

SMALL-SCALE LAB

Small-Scale Lab

PURPOSE After completing this activity, students will be able to

- recognize and describe precipitates as well as
- write the names and formulas for each.

SKILLS FOCUS observing, applying rules,

PREP TIME 1 hour

CLASS TIME 30 minutes

ADVANCED PREPARATION

Solution	Preparation
0.05*M* $AgNO_3$	2.1 g in 250 mL
0.2*M* $Pb(NO_3)_2$	16.6 g in 250 mL
0.5*M* $CaCl_2$	13.9 g in 250 mL
1.0*M* Na_2CO_3	26.5 g in 250 mL
0.1*M* Na_3PO_4	9.5 g $Na_3PO_4 \cdot 12H_2O$ in 250 mL
0.5*M* NaOH	20.0 g in 1.0 L
0.2*M* Na_2SO_4	7.1 in 250 mL
0.2*M* $CuSO_4$	12.5 g $CuSO_4 \cdot 5H_2O$ in 250 mL
0.2*M* $MgSO_4$	6.0 g in 250 mL
0.1*M* $FeCl_3$	6.8 g $FeCl_3 \cdot 6H_2O$ in 25 mL of 1.0*M* NaCl (for stability); dilute to 250 mL

EXPECTED OUTCOME

In Figure A, a, f, g, h, and j: milky white; b and k: cloudy white; e: cloudy tan; i and l: grainy white; c: muddy brown; d: no visible reaction. In Figure B, a, b, and c: orange; e, f, and g: white; i, j, and k: blue; d, h, and l: no visible reaction.

ANALYZE AND CONCLUDE

1. $AgNO_3$ and Na_2SO_4 did not form a precipitate.
2. **a.** Ag_2CO_3, silver carbonate
   b. Ag_3PO_4, silver phosphate
   c. AgOH, silver hydroxide (Note: The product is actually Ag_2O, silver oxide.)
   e. $PbCO_3$, lead(II) carbonate
   f. $Pb_3(PO_4)_2$, lead(II) phosphate
   g. $Pb(OH)_2$, lead(II) hydroxide
   h. $PbSO_4$, lead(II) sulfate
   i. $CaCO_3$, calcium carbonate
   j. $Ca_3(PO_4)_2$, calcium phosphate
   k. $Ca(OH)_2$, calcium hydroxide
   l. $CaSO_4$, calcium sulfate

STUDY GUIDE

Evaluate

Review and Assessment Materials

WALK-THROUGH TUTORIALS Each of the Skills Tune-Up problems on the following page has an animated step-by-step tutorial that explains the problem-solving strategy in detail.

PROBLEM SETS Have students practice writing formulas, naming compounds, and calculating mass ratios using the Chapter 9 Online Problem Set.

MATH SKILLS Have struggling students practice solving algebraic equations using the MathXL learning module.

Study Tip

As you review each section, write down the key concepts that are found in bold print in each major division. Then add details and extensions until you have a complete outline of the topic.

9 Study Guide

BIG IDEAS THE STRUCTURE OF ATOMS; BONDING AND INTERACTIONS

An element's position in the periodic table supplies information on ion formation and bonding tendencies, which is used to write the names and formulas of ions and compounds. Ionic and molecular compounds differ in composition—ions form ionic compounds and molecules form molecular compounds.

9.1 Naming Ions

When metals in Groups 1A, 2A, and 3A lose electrons, they form cations with charges equal to their group number. The charge of any ion of a Group A nonmetal is determined by subtracting 8 from the group number. The charges of the cations of many transition metals must be determined from the number of electrons lost.

A polyatomic ion is composed of more than one atom that behaves as a unit and carries a charge.

- monatomic ion (264)

9.2 Naming and Writing Formulas for Ionic Compounds

To write the formula of a binary ionic compound, write the symbol of the cation and then the anion. Then balance the charges. The name of a binary ionic compound is the cation name followed by the anion name.

To write formulas for compounds with polyatomic ions, write the symbol for the cation followed by the symbol for the anion. Then balance the charges. To name a compound containing a polyatomic ion, state the cation name followed by the anion name.

- binary compound (272)

9.3 Naming and Writing Formulas for Molecular Compounds

To name a binary molecular compound, write the names of the elements in the order listed in the formula. Use prefixes to indicate the number of each atom. End the name of the second element with *-ide*.

To write the formula of a binary molecular compound, use the prefixes to determine the subscript of each element. Write the symbols for the elements with the subscripts.

9.4 Naming and Writing Formulas for Acids and Bases

If the anion name ends in *-ide*, the acid name begins with the prefix *hydro-*. The stem of the anion has the suffix *-ic* and is followed by the word *acid*. If the anion name ends in *-ite*, the acid name is the stem of the anion with the suffix *-ous*, followed by the word *acid*. If the anion name ends in *-ate*, the acid name is the stem of the anion with the suffix *-ic*, followed by the word *acid*. To write the formula for an acid, use the rule for writing the name of the acid in reverse.

Bases are named like other ionic compounds. To write the formula for a base, write the symbol for the metal cation followed by that of the hydroxide ion. Then, balance the ionic charges.

- acid (285)
- base (287)

9.5 The Laws Governing How Compounds Form

If the ratio of atoms of each element in a compound is fixed, then the ratio of their masses is also fixed.

Follow the rules for naming acids when H is the first element. If the compound is binary, generally the name ends with *-ide*. For a molecular binary compound, use prefixes to indicate the number of atoms. When a polyatomic ion with oxygen is in the formula, the compound name ends in *-ite* or *-ate*. If the compound contains a metallic cation that can have different ionic charges, use a Roman numeral to indicate the ionic charge.

An *-ide* ending usually indicates a binary compound. An *-ite* or *-ate* ending indicates a polyatomic ion with oxygen. Prefixes usually indicate a molecular compound. A Roman numeral after the name of a cation shows the ionic charge of the cation.

- law of definite proportions (289)
- law of multiple proportions (290)

UbD Performance Tasks

IT'S PROPORTIONAL Have students create a poster explaining the law of multiple proportions using copper(I) oxide and copper(II) oxide as their example compounds. Explanations should include supporting mass ratio equations.

WHAT'S IN A NAME? Have students use the following quote as the opening statement in an article for the school newspaper. *What's in a name?* The article should convey the importance for knowing and understanding the information needed and the information gained from the name and formula of a compound. The article should use as least six different commonly used compounds as examples. Encourage students to include graphics or illustrations as needed to enhance the article.

Skills Tune-Up: Names and Formulas

Problem	❶ Analyze	❷ Solve
Write the name for the binary ionic compound CrI_2.	Name the ions in the order written in the formula. Use a Roman numeral if the metal cation in the compound can have more than one common ionic charge. Hint: Refer to Sample Problems 9.2–9.3 if you have trouble identifying binary ionic compounds.	CrI_2 contains chromium cations and iodide anions. Chromium forms two common cations: Cr^{2+} and Cr^{3+}. The compound CrI_2 is electrically neutral. Iodide ion is I^- and the formula CrI_2 specifies two iodide ions, which give a charge of 2−. So the chromium ion must be Cr^{2+}. The name of the compound is chromium(II) iodide.
Write the name for the binary molecular compound N_2O_5. Hint: Review Sample Problem 9.6 if you need help naming binary molecular compounds.	Name the elements in the order written in the formula. Use prefixes as necessary to indicate the number of each kind of atom. Use the suffix *-ide* on the name of the second element.	N_2O_5 is composed of two nitrogen atoms and five oxygen atoms. The name of the compound is dinitrogen pentoxide.
Write the formula for the ionic compound aluminum sulfate.	Write the symbol or formula for each ion in the order written in the name. Use subscripts to balance the charges. The ions must be combined in the lowest whole-number ratio. Use parentheses if more than one polyatomic ion is needed to balance a formula.	Aluminum sulfate contains Al^{3+} cations and SO_4^{2-} anions.  The formula for aluminum sulfate is $Al_2(SO_4)_3$. Remember: Use parentheses when there is more than one polyatomic ion in the balanced formula.
Write the formula for the binary molecular compound selenium dioxide. Remember: The number 1 is never used as a subscript in a formula.	The prefixes in the name indicate the subscript of each element in the formula. Write the symbols for the two elements with the appropriate subscripts.	Selenium dioxide is composed of one selenium atom and two oxygen atoms. The formula for selenium dioxide is written as SeO_2.

Focus on ELL

5 ASSESS UNDERSTANDING Assign ELL students one of the Performance Tasks as a group for an alternative assessment. Provide guidelines for the assignment and a grading rubric.

BEGINNING

LOW Direct students to create the visual representation for the assignment.

HIGH Direct students to find specific information needed for the assignment from the text.

INTERMEDIATE: LOW/HIGH Direct students to provide the written explanation for the visuals.

ADVANCED: LOW/HIGH Direct students to present the groups' assignment to the class.

Skills Tune-Up

Example and sample practice problems for writing formulas, naming compounds, and calculating mass ratios can be found on the following pages:

LESSON 9.1 Naming Cations and Anions—page 267

LESSON 9.2 Writing Formulas for Binary Ionic Compounds—page 273; Naming Binary Ionic Compounds—page 275; Writing Formulas for Compounds with Polyatomic Ions—page 277; Naming Compounds with Polyatomic Ions—page 278

LESSON 9.3 Naming Binary Molecular Compounds—page 282; Writing Formulas for Binary Molecular Compounds—page 283

LESSON 9.4 Naming Acids—page 287; Naming Bases—page 288

LESSON 9.5 Calculating Mass Ratios—page 291

ASSESSMENT

Evaluate

Answers

LESSON 9.1

57. **a.** 2− **b.** 1+ **c.** 1− **d.** 3+
58. **a.** 2+ **b.** 2+ **c.** 3+ **d.** 1+
59. **a.** barium ion **b.** iodide ion
c. silver ion **d.** mercury(II) ion
60. cyanide ion, CN^-, and hydroxide ion, OH^-
61. **a.** hydroxide ion **b.** lead(IV) ion
c. sulfate ion **d.** oxide ion

LESSON 9.2

62. zero; A compound is electrically neutral.
63. The symbols for the cation and anion are written, and the charges are balanced with subscripts. The name of the cation is followed by the name of the anion.
64. Determine the charge of the anion then work the formula backward to find the charge of the transition metal cation needed to give a net charge of zero for the formula unit.
65. The symbols for the cation and anion are written, and the charges are balanced with subscripts. Parentheses are used around the polyatomic ion if a subscript is needed. The name of the cation is followed by the name of the anion.
66. **a.** NH_4NO_3, ammonium nitrate
b. $Sn(NO_3)_4$, tin(IV) nitrate
c. $Fe(NO_3)_3$, iron(III) nitrate
d. $Mg(NO_3)_2$, magnesium nitrate
e. $(NH_4)_2CO_3$, ammonium carbonate
f. $Sn(CO_3)_2$, tin(IV) carbonate
g. $Fe_2(CO_3)_3$, iron(III) carbonate
h. $MgCO_3$, magnesium carbonate
i. NH_4CN, ammonium cyanide
j. $Sn(CN)_4$, tin(IV) cyanide
k. $Fe(CN)_3$, iron(III) cyanide
l. Mg(CN)2, magnesium cyanide
m. $(NH4)_3PO_4$, ammonium phosphate
n. $Sn_3(PO_4)_4$, tin(IV) phosphate
o. $FePO_4$, iron(III) phosphate
p. $Mg_3(PO_4)_2$, magnesium phosphate
67. **a** and **c**
68. when more than a single polyatomic ion is needed to balance the formula

LESSON 9.3

69. two nonmetals
70. **a.** tri- **b.** mono- **c.** di-
d. hexa- **e.** penta- **f.** tetra-
71. For formulas, write the correct symbols for each element with a subscript corresponding to the prefix before each element in the name. For naming, name each element in the order given. Use the subscript to determine the prefix before each element in the name. The name ends in *-ide*.
72. **a.** diphosphorus pentoxide
b. carbon tetrachloride
c. BCl_3 **d.** N_2H_4

9 Assessment

* Solutions appear in Appendix E

Lesson by Lesson

9.1 Naming Ions

57. Give the expected charges on the ions of elements of these groups of the periodic table.
a. Group 6A **c.** Group 7A
b. Group 1A **d.** Group 3A

***58.** Give the expected charge of the cations of the following elements:
a. Sr **b.** Ca **c.** Al **d.** Cs

59. Name these ions, using Table 9.2, if necessary.
a. Ba^{2+} **b.** I^- **c.** Ag^+ **d.** Hg^{2+}

60. Write the names and formulas of the two polyatomic anions in Table 9.3 with names that do not end in *-ite* or *-ate*.

61. Name the following ions:
a. OH^- **b.** Pb^{4+} **c.** SO_4^{2-} **d.** O^{2-}

9.2 Naming and Writing Formulas for Ionic Compounds

62. What is the net charge of every ionic compound? Explain.

63. How are chemical formulas written for binary ionic compounds, given their names? How is the reverse done?

***64.** How do you determine the charge of a transition metal cation from the formula of an ionic compound containing that cation?

65. How are formulas written for ionic compounds with polyatomic ions, given their names? How is the reverse done?

66. Complete the table by writing correct formulas for the compounds formed by combining positive and negative ions. Then name each compound.

	NO_3^-	CO_3^{2-}	CN^-	PO_4^{3-}
NH_4^+	a.____	e.____	i.____	m.____
Sn^{4+}	b.____	f.____	j.____	n.____
Fe^{3+}	c.____	g.____	k.____	o.____
Mg^{2+}	d.____	h.____	l.____	p.____

67. Which of the following compounds are binary ionic compounds?
a. KBr
b. K_3PO_4
c. sodium nitride
d. calcium sulfate

68. When must parentheses be used in a formula for a compound?

9.3 Naming and Writing Formulas for Molecular Compounds

69. What are the components of a binary molecular compound?

***70.** What prefix indicates each of the following numbers of atoms in the formula of a binary molecular compound?
a. 3 **b.** 1 **c.** 2 **d.** 6 **e.** 5 **f.** 4

71. How are formulas for binary molecular compounds written, given their names? How is the reverse performed, given their formulas?

72. Write the formula or name for the following compounds:
a. P_2O_5
b. CCl_4
c. boron trichloride
d. dinitrogen tetrahydride

9.4 Naming and Writing Formulas for Acids and Bases

73. Give the name or the formula for these acids.
a. HCl **c.** sulfuric acid
b. HNO_3 **d.** acetic acid

74. Is every compound that contains hydrogen an acid? Explain.

75. Write formulas for these compounds.
a. nitrous acid
b. aluminum hydroxide
c. hydroselenic acid
d. strontium hydroxide
e. phosphoric acid

***76.** Write names or formulas for these compounds.
a. $Pb(OH)_2$ **c.** copper(II) hydroxide
b. $Co(OH)_2$ **d.** iron(II) hydroxide

LESSON 9.4

73. **a.** hydrochloric acid
b. nitric acid
c. H_2SO_4
d. $HC_2H_3O_2$
74. No, to be an acid the compound must produce H^+ ions in an aqueous solution.
75. **a.** HNO_2 **b.** $Al(OH)_3$
c. H_2Se **d.** $Sr(OH)_2$
e. H_3PO_4
76. **a.** lead(II) hydroxide
b. cobalt(II) hydroxide
c. $Cu(OH)_2$
d. $Fe(OH)_2$

9.5 The Laws Governing How Compounds Form

77. What is the law of definite proportions?

78. Describe the law of multiple proportions.

*79. Nitrous oxide, laughing gas, is used as an anesthetic in dentistry. The mass ratio of nitrogen to oxygen is 7:4. A 68-g sample of a compound composed of nitrogen and oxygen contains 42 g of nitrogen. Is the sample nitrous oxide?

Understand Concepts

80. Write formulas for these compounds.
   a. potassium permanganate
   b. calcium hydrogen carbonate
   c. dichlorine heptoxide
   d. trisilicon tetranitride
   e. sodium dihydrogen phosphate
   f. phosphorus pentabromide

81. Write formulas for these compounds.
   a. magnesium sulfide
   b. sodium phosphite
   c. barium hydroxide
   d. copper(II) nitrite
   e. potassium sulfite
   f. calcium carbonate
   g. sodium bromide
   h. ferric sulfate

*82. Name these compounds.
   a. $NaClO_3$
   b. Hg_2Br_2
   c. K_2CrO_4
   d. $HClO_4$
   e. SnO_2
   f. $Fe(C_2H_3O_2)_3$
   g. $KHSO_4$
   h. $Ca(OH)_2$
   i. BaS

83. Name each substance.
   a. $LiClO_4$
   b. Cl_2O
   c. HgF_2
   d. CaO
   e. $Ba_3(PO_4)_2$
   f. I_2
   g. $SrSO_4$
   h. $CuC_2H_3O_2$
   i. $SiCl_4$

84. Name each compound.
   a. $Mg(MnO_4)_2$
   b. $Be(NO_3)_2$
   c. K_2CO_3
   d. N_2H_4
   e. LiOH
   f. BaF_2
   g. PI_3
   h. ZnO
   i. H_3PO_3

85. Write formulas for these compounds.
   a. calcium bromide
   b. silver chloride
   c. aluminum carbide
   d. nitrogen dioxide
   e. tin(IV) cyanide
   f. lithium hydride
   g. strontium acetate
   h. sodium silicate

*86. A compound of general formula Q_xR_y contains no hydrogen, and Q and R are both elements. Neither Q nor R is a metal. Is Q_xR_y an acid, a binary ionic compound, or a binary molecular compound?

87. A compound of general formula Q_xR_y contains no hydrogen, Q is the alkali metal of lowest atomic mass, and R contains the elements oxygen and carbon in a 3:1 ratio. Write the name and the formula of the compound.

*88. Two compounds contain only tin and chlorine. The ratio of the masses of chlorine combined with 1.00 g of tin in the two compounds is 2:1. If one compound has the formula $SnCl_2$, what is the formula for the other compound?

89. Analysis of two compounds shows that they contain only lead and iodine in these amounts:

Compound I: 22.48 g Pb and 27.52 g I
Compound II: 5.80 g Pb and 14.20 g I

   a. Determine the ratio of lead contained in the two compounds for every 1 g of iodine.
   b. Use your ratio and your knowledge of ionic charges to write the formulas and the names of the two compounds.

90. The U.S. produces thousands of inorganic chemicals. Inorganic chemicals, for the most part, do not contain carbon. The table shows the amounts (in billions of kg) of the top ten inorganic chemicals produced in a recent year.

Chemical name	Amount produced (10^9 kg)
Sulfuric acid	39.4
Nitrogen	26.9
Oxygen	17.7
Ammonia	16.5
Lime	16.3
Phosphoric acid	11.2
Sodium hydroxide	11.0
Chlorine	10.3
Sodium carbonate	9.3
Nitric acid	6.8

   a. What percentage of the total production of the top ten is lime (calcium oxide)?
   b. Three diatomic gases are on the list. What are their names? What was the combined production of these gases in billions of kilograms?
   c. The three acids make up what percentage of the total production of the top ten?
   d. Write formulas for the top ten inorganic chemicals.

ASSESSMENT

LESSON 9.5

77. In all samples of the same chemical compound, the masses of the elements are always in the same proportions.
78. Whenever two elements form more than one compound, the different masses of one element that combine with the same mass of the other element are in a ratio of small whole numbers.
79. No; The ratio of nitrogen to oxygen is 42:26, which is not a 7:4 ratio.

UNDERSTAND CONCEPTS

80. a. $KMnO_4$ b. $Ca(HCO_3)_2$ c. Cl_2O_7 d. Si_3N_4 e. NaH_2PO_4 f. PBr_5
81. a. MgS b. Na_3PO_3 c. $Ba(OH)_2$ d. $Cu(NO_2)_2$ e. K_2SO_3 f. $CaCO_3$ g. NaBr h. $Fe_2(SO_4)_3$
82. a. sodium chlorate
   b. mercury(I) bromide
   c. potassium chromate
   d. perchloric acid
   e. tin(IV) oxide
   f. iron(III) acetate
   g. potassium hydrogen sulfate
   h. calcium hydroxide
   i. barium sulfide
83. a. lithium perchlorate
   b. dichlorine monoxide
   c. mercury(II) fluoride
   d. calcium oxide
   e. barium phosphate
   f. iodine
   g. strontium sulfate
   h. copper(I) acetate
   i. silicon tetrachloride
84. a. magnesium permanganate
   b. beryllium nitrate
   c. potassium carbonate
   d. dinitrogen tetrahydride
   e. lithium hydroxide
   f. barium fluoride
   g. phosphorus triiodide
   h. zinc oxide
   i. phosphorous acid
85. a. $CaBr_2$ b. AgCl c. Al_4C_3 d. NO_2 e. $Sn(CN)_4$ f. LiH g. $Sr(C_2H_3O_2)_2$ h. Na_2SiO_3
86. binary molecular compound
87. lithium carbonate, Li_2CO_3
88. $SnCl_4$
89. a. 2:1 b. PbI_2, lead(II) iodide, and PbI_4, lead(IV) iodide
90. a. 9.85%
   b. nitrogen, oxygen, and chlorine; 54.9 billions of kg
   c. 34.7%
   d. H_2SO_4, N_2, O_2, NH_3, CaO, H_3PO_4, NaOH, Cl_2, Na_2CO_3, HNO_3

ASSESSMENT

Answers

THINK CRITICALLY

91. A molecular formula shows the number of each kind of atom in a molecule of the compound. The formula unit shows the lowest whole-number ratio of ions in a compound.

92. on the right side

93. Common names vary in different languages and are difficult to remember and convert to formulas.

94. The statement is true for the representative metals but not for the transition metals, which often can have different charges.

95. Possible answers include: cations always come before anions; when a cation has more than one ionic charge, the charge is indicated by a Roman numeral; monatomic anions use an *-ide* ending. Each rule has a specific purpose; for example, an ionic charge is necessary information because it determines how many ions are in the formula unit of the compound.

96. a. N_2O, dinitrogen monoxide
b. NO_2, nitrogen dioxide
c. NO, nitrogen monoxide
d. N_2O_4, dinitrogen tetroxide

97. a. Cu_2S, copper(I) sulfide, and CuS, copper(II) sulfide
b. $FeSO_4$, iron(II) sulfate, and $Fe_2(SO_4)_3$, iron(III) sulfate
c. PbO, lead(II) oxide, and PbO_2, lead(IV) oxide
d. MnF_2, manganese(II) fluoride, and MnF_3, manganese(III) fluoride

98. a. The charges do not balance, CsCl.
b. Neon does not form compounds.
c. The charges do not balance, ZnO.
d. The subscripts are not the lowest whole-number ratio, BaS.

99. $NaAl(SO_4)_2$

100. binary ionic compounds: *d* and *g*; binary molecular compounds: *a* and *f*; compounds with polyatomic ions: *b, c, e, h,* and *i;* acids: *b* and *e;* base: *c*

101. a. 3.60 g solid/1.40 g gas = 2.57 and 6.48 g solid/2.52 g gas = 2.57
The compound obeys the law of definite proportions.
b. 3.92 g

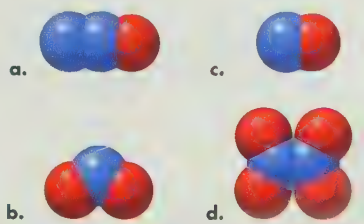
102. law of conservation of mass

103. a. $CaCO_3$ and $Mg(OH)_2$
b. NaF and KNO_3
c. TiO_2 and ZnO
d. $FeSO_4$

104. a. PCl_3, phosphorus trichloride, molecular
b. S_2Cl_2, disulfur dichloride, molecular
c. CCl_4, carbon tetrachloride, molecular
d. SCl_2, sulfur dichloride, molecular

Think Critically

91. Compare and Contrast How does the information conveyed by a molecular formula differ from that given by a formula unit of a compound?



92. Make Generalizations Where on the periodic table will you find the two elements in a binary molecular compound?

93. Draw Conclusions Why is it important for chemists to have a system of writing chemical names and formulas?

94. Evaluate Criticize this statement: "The ionic charge of any metal can be determined from the position of the element in the periodic table."

95. Explain Summarize the rules that chemists use for naming ionic compounds. What is the purpose for each rule?

***96. Use Models** Nitrogen and oxygen form a number of stable chemical compounds. In the models below, nitrogen is blue; oxygen is red. Write the molecular formula and name of each.

97. Evaluate and Revise Examine the following names for ionic compounds. Show, by writing all possible formulas for the compounds, that the names are incomplete. Then, write each complete name.

a. copper sulfide
b. iron sulfate
c. lead oxide
d. manganese fluoride

***98. Evaluate and Revise** Explain what is wrong with each formula. Write the correct formula.

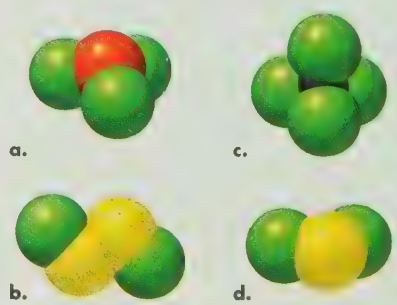
a. $CsCl_2$
b. LiNe
c. ZnO_2
d. Ba_2S_2

99. Infer Sodium aluminum sulfate is an active ingredient in baking powder. The molecular formula for this ionic compound contains two sulfate ions. Write the complete molecular formula for sodium aluminum sulfate.

***100. Classify** Separate the following compounds into five categories: binary ionic compounds, binary molecular compounds, compounds with polyatomic ions, acids, and bases. Some compounds may fit in more than one category.

a. CBr_4
b. HCN
c. NH_4OH
d. MgS
e. H_2SiO_3
f. ClBr
g. Al_2O_3
h. Na_2HPO_4
i. $KMnO_4$

***101. Calculate** A student heats 5.00 g of a white compound and obtains 3.60 g of a green compound and 1.40 g of a colorless gas. Another student heats a 9.00-g sample of the same compound and obtains 6.48 g of a green compound and 2.52 g of a colorless gas.



a. Show by calculation that the white compound obeys the law of definite proportions.
b. If a third student heats 14.0 g of the white compound, how many grams of colorless gas will be produced?

***102. Draw Conclusions** What other law is illustrated (twice) by the experiment described in the previous question?

103. Apply Concepts Ionic compounds are present in items commonly found in your home. Write formulas for the ionic compounds found in the following common household products:

a. antacid (calcium carbonate and magnesium hydroxide)
b. toothpaste for sensitive teeth (sodium fluoride and potassium nitrate)
c. sunscreen (titanium(IV) oxide and zinc oxide)
d. pasta (ferrous sulfate)

104. Use Models In the models below, chlorine is green; phosphorus is orange; carbon is black; and sulfur is yellow. Write the formula and the name for each compound. Are these compounds ionic or molecular compounds?

Enrichment

105. Organize Data *CRC Handbook of Chemistry and Physics* is a reference book that contains a wealth of information about elements and compounds. Two sections of this book that you might use are called "Physical Constants of Inorganic Compounds" and "Physical Constants of Organic Compounds." To familiarize yourself with this work, make a table with these headings: Name, Formula, Crystalline Form or Color, Density, Melting Point (°C), Boiling Point (°C), and Solubility in Water.

Name	Formula	Crystalline Form or Color	Density	MP (°C)	BP (°C)

Enter these substances in the body of the table: ammonium chloride, barium, barium sulfate, bromine, calcium carbonate, chlorine, copper(II) sulfate pentahydrate, iodine, iron(II) sulfate pentahydrate, mercury, potassium carbonate, and sulfur. Use the handbook to complete the table.

***106. Analyze Data** Use the table you prepared for Problem 105 to answer the following questions:

- **a.** You have two unlabeled bottles, each containing a white powder. One of the substances is calcium carbonate, and the other is potassium carbonate. How could you distinguish between these two compounds?
- **b.** How would you distinguish between samples of copper(II) sulfate pentahydrate and iron(II) sulfate pentahydrate?
- **c.** A bottle contains a mixture of ammonium chloride and barium sulfate. How could you separate these two compounds?
- **d.** List the elements in the table in order of increasing density. Identify the elements as metals or nonmetals.
- **e.** List the compounds in the table in order of decreasing density.
- **f.** Calculate the mass of 47.0 cm^3 of mercury.
- **g.** Calculate the volume of 16.6 g of sulfur.
- **h.** How would you distinguish among the Group 7A elements listed in the table?

Write About Science

107. Research a Problem Sodium ions (Na^+) and potassium ions (K^+) are needed for the human body to function. Deficiencies in these ions can have adverse effects on your health. Research where these ions are most likely to be found in the body and the roles they play. Write a brief essay describing your findings.

108. Explain Investigate the role of lithium carbonate in the successful treatment of bipolar disorder. Write a brief report that includes information on bipolar disorder and why lithium carbonate is used to treat it.

109. Connect to the **BIG**IDEA Choose five personal care products from your home. Read each ingredient label and identify all the compounds that you are able to decipher. Write a short paragraph in which you explain how learning to name chemical compounds has helped you decipher these ingredient labels.

CHEMYSTERY

Cucumber Blunder

Tara called her grandmother to find out what she did wrong. She started to describe what she had done. When Tara mentioned squeezing limes, her grandmother interrupted and explained: lime, in this case, meant pickling lime, not the citrus fruit. "Pickling lime? I've never heard of that!" Tara exclaimed.

Her grandmother fetched a package of pickling lime from the cupboard to look at the ingredient label. She read aloud "food-grade calcium hydroxide." Her grandmother elaborated, "That's what makes the pickles crunchy like you like 'em."

110. Compare Lime is the common name for calcium hydroxide. What are the advantages and disadvantages of each name?

***111.** Connect to the **BIG**IDEA Is calcium hydroxide an ionic or a molecular compound? Write the formula.

CHEMYSTERY

START A CONVERSATION Have students read through the CHEMystery. **Ask** What do you think led Tara to make a mistake when buying her pickle ingredients? *(The recipe simply referred to "lime," and there is more than one type of lime available in the grocery store.)* **Ask** Does the ingredient name *lime* provide useful information about the ingredient's composition? *(no)* **Ask** What can the name *calcium hydroxide* tell you about the composition of the ingredient? *(The compound contains the ions Ca^{2+} and OH^-.)*

APPLY CONCEPTS Have students determine the chemical formula of calcium hydroxide from its name. *($Ca(OH)_2$)* **Ask** Is it an acid or a base? *(base)* Why? *(It is an ionic compound that will produce hydroxide ions when it is dissolved in water.)*

CHEMYSTERY ANSWERS

110. The common name is shorter and easier to remember, but *lime* can also refer to calcium oxide, leading to uncertainty in which compound is intended. When the IUPAC name, calcium hydroxide, is used, the intended compound is clear to those trained in chemistry. For those not trained in chemistry, the IUPAC name may be unfamiliar.

111. BIGIDEA ionic; $Ca(OH)_2$

ASSESSMENT

Answers

ENRICHMENT

105. Spot check student answers.

106. a. Potassium carbonate has greater water solubility than $CaCO_3$.

b. The copper compound is blue; the iron compound is white.

c. Add water to dissolve the NH_4Cl, and then filter out the insoluble $BaSO_4$.

d. chlorine (nonmetal), sulfur (nonmetal), bromine (nonmetal), barium (metal), iodine (nonmetal), mercury (metal)

e. barium sulfate, calcium carbonate, potassium carbonate, copper(II) sulfate pentahydrate, iron(II) sulfate pentahydrate, ammonium chloride

f. 639 g **g.** 8.02 cm^3 **h.** color, density, melting point, and boiling point

WRITE ABOUT SCIENCE

107. Sodium is found in higher concentrations in extra-cellular fluids, such as plasma. Potassium is found in higher concentrations within cells. Both ions are involved in transmission of nerve impulses.

108. Answers should mention that lithium carbonate is used because it is effective in regulating the patient's mental state.

109. Answers will vary.

Answers

CUMULATIVE REVIEW

112. Answers may include: color (physical), solid (physical), magnetic (physical), conducts electricity (physical), burns (chemical).

113. **a.** 4 **b.** 2 **c.** 2 **d.** 4 **e.** 2 **f.** 1

114. 5.2 cm

115. **a.** 7.75×10^5 µL **b.** 208 K **c.** 0.832 cg

116. 0.538 g/cm^3

117. Both are in the nucleus and have a mass of about 1 amu. A proton is positively charged; a neutron has no charge.

118. **a.** 2 **b.** protons **c.** electrons **d.** neutrons

119. **a.** neon **b.** carbon **c.** boron **d.** helium

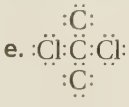
120. The metalloids border a line separating the metals from the nonmetals. Their properties are intermediate between those of metals and nonmetals.

121. **a.** cesium, potassium, sodium, lithium
b. lithium, boron, carbon, fluorine, neon

122. **a.** Li **b.** I **c.** S **d.** O **e.** N **f.** F

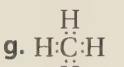
123. When metallic elements of Group 1A and 2A form ions, they lose all their outer shell electrons. This increases the attraction by the nucleus for the fewer remaining electrons and results in ions that are smaller than the neutral atoms. The electron that a Group 7A element gains in forming an ion enters the outer shell, resulting in a decrease in the effective nuclear attraction of the increased number of electrons. The anion is larger than the neutral atom.

124. **a.** 1 **b.** 6 **c.** 8 **d.** 2 **e.** 7 **f.** 5



125. $1s^22s^22p^6$; Possible answers are N^{3-}, O^{2-}, F^-, Na^+, Mg^{2+}, and Al^{3+}.

126. **a.** 12 p^+ and 10 e^- **b.** 35 p^+ and 36 e^-
c. 38 p^+ and 36 e^- **d.** 16 p^+ and 18 e^-



127. b and c; molecular compounds formed by two nonmetals have covalent bonds.

128. b, d, and f

129. **a.** :$\ddot{\text{Cl}}$:$\ddot{\text{Cl}}$: **b.** :C:::O: **c.** :Ö::C::Ö:

d.

e.

f.

g.

130. A hydrogen bond is an intermolecular force between a hydrogen atom covalently bonded to a very electronegative atom and an unshared pair of electrons on another electronegative atom.

131. ionic bond: electrons are transferred

$$Na\cdot + \cdot\ddot{F}: \rightarrow Na^+ \; :\ddot{F}:^-$$

covalent bond: electrons are shared

$$H\cdot + \cdot H \rightarrow H:H$$

Cumulative Review

112. List five properties of the chair you are sitting on. Classify each as physical or chemical.

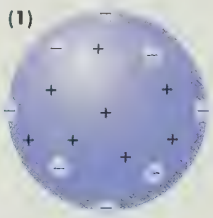
***113.** How many significant figures are in the following measurements?

a. 15.05 g **d.** 300.0 cm^3
b. 0.31 cm **e.** 3.0×10^5 kg
c. 890 mL **f.** 0.001 mm

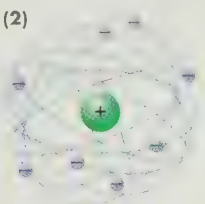
114. Determine the sum of the following measurements to the correct number of significant figures.

1.55 cm + 0.235 cm + 3.4 cm

115. Make the following conversions:



a. 775 mL to microliters (µL)
b. 65°C to K
c. 8.32 mg Ag to centigrams of silver (cg Ag)



116. A student finds that 6.62 g of a substance occupies a volume of 12.3 cm^3. What is the density of the substance?

117. Compare neutrons and protons with respect to their charge, mass, and position in the atom.

***118.** The diagrams show two models of the atom.

a. Which model is more accurate?
b. What do the positively charged particles represent?
c. What do the negatively charged particles represent?
d. What major subatomic particle is missing in both of these models?

(1)

(2)

***119.** What elements have these electron configurations?

a. $1s^22s^22p^6$ **c.** $1s^22s^22p^1$
b. $1s^22s^22p^2$ **d.** $1s^2$

120. Where are the metalloids found on the periodic table? Compare the properties of the metalloids to metals and nonmetals.

121. Arrange the following groups of elements in order of increasing ionization energy.

a. potassium, cesium, lithium, sodium
b. fluorine, boron, lithium, carbon, neon

122. From the positions of the elements in the periodic table, choose the element in each pair with the higher electronegativity.

a. Cs and Li **c.** S and Mg **e.** Te and N
b. Sr and I **d.** O and Se **f.** C and F

123. The ions of the elements of Groups 1A and 2A have smaller radii than their neutral atoms, whereas the ions of Group 7A have larger radii than their neutral atoms. Explain.

***124.** How many valence electrons do atoms of the following elements have?

a. lithium **d.** calcium
b. sulfur **e.** bromine
c. neon **f.** phosphorus

125. Write the electron configuration for the element neon, then identify three ions that have the same electron configuration.

126. How many protons and electrons are in each ion?

a. magnesium ion **c.** strontium ion
b. bromide ion **d.** sulfide ion

***127.** Which of these compounds would you expect to contain covalent bonds? Why?

a. KCl **b.** PBr_3 **c.** ClBr **d.** NaI

128. Which of these substances would you expect to be polar?

a. Cl_2 **c.** CO_2 **e.** CCl_4 **g.** CH_4
b. CO **d.** NH_3 **f.** H_2O

129. Draw electron dot structures for the substances in Question 128.

130. Explain what a hydrogen bond is and under what conditions a hydrogen bond will form.

131. Explain the difference between an ionic bond and a covalent bond. Use electron dot structures to illustrate your explanation.

Standardized Test Prep for Indiana

Standards: C.3.4, C.3.5

Select the choice that best answers each question or completes each statement.

1. Identify the pair in which the formula does not match the name.
   (A) sulfite, SO_3^{2-} **(C)** hydroxide, OH^-
   (B) nitrite, NO_3^- **(D)** dichromate, $Cr_2O_7^{2-}$

2. Which of these compounds are ionic?
   I. $CaSO_4$ II. N_2O_4 III. NH_4NO_3 IV. CaS
   (A) I and II only **(C)** III and IV only
   (B) II and III only **(D)** I, III, and IV only

3. What is the name of $AlCl_3$?
   (A) aluminum trichloride
   (B) aluminum(III) chloride
   (C) aluminum chlorite
   (D) aluminum chloride

4. The Roman numeral in manganese(IV) sulfide indicates the
   (A) group number on the periodic table.
   (B) positive charge on the manganese ion.
   (C) number of manganese ions in the formula.
   (D) number of sulfide ions needed in the formula.

Tips for Success

Eliminate Wrong Answers If you don't know which choice is correct, start by eliminating those you know are wrong. If you can rule out some choices, you'll increase your chances of choosing the correct answer.

5. Which of these statements does not describe every binary molecular compound?
   (A) Molecules of binary molecular compounds are composed of two atoms.
   (B) The names of binary molecular compounds contain prefixes.
   (C) The names of binary molecular compounds end in the suffix *-ide*.
   (D) Binary molecular compounds are composed of two nonmetals.

6. What is the formula of ammonium carbonate?
   (A) NH_4CO_3 **(C)** NH_3CO_4
   (B) $(NH_4)_2CO_3$ **(D)** NH_4CO_2

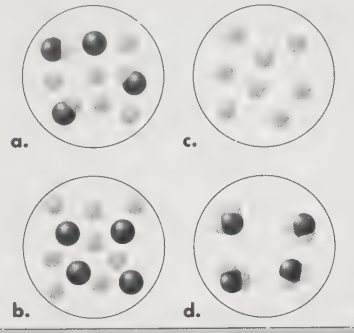
The lettered choices below refer to Questions 7–10.

(A) QR **(B)** QR_2 **(C)** Q_2R **(D)** Q_2R_3

Which formula shows the correct ratio of ions in the compound formed by each pair of elements?

	Element Q	Element R
7.	aluminum	sulfur
8.	potassium	oxygen
9.	lithium	chlorine
10.	strontium	bromine

Use the data table to answer Questions 11–12. The table gives formulas for some of the ionic compounds formed when cations (M, N, P) combine with anions (A, B, C, D).



Cation	Anion			
	A	B	C	D
M	MA_2	(1)	(2)	MD
N	(3)	N_2B	(4)	(5)
P	PA_3	(6)	PC	$P_2(D)_3$

11. Use the given formulas to determine the ionic charge of each cation and anion.

12. Write formulas for compounds (1) through (6).

Use the atomic windows to answer Question 13.

13. Classify the contents as elements only, compounds only, or elements and compounds.

Materials List

For the Student

Small-Scale Lab, p 324
- 1 teaspoon each of water, sodium chloride, and calcium carbonate
- plastic spoon
- weighing paper
- watchglass or small beaker
- balance
- paper
- pencil
- ruler

Quick Lab, p 328
- centigram balance
- burner
- 3 medium-sized test tubes
- test-tube holder
- test-tube rack
- spatula
- 2–3 g each of hydrated salts of copper(II) sulfate, calcium chloride, and sodium sulfate

For the Teacher

Teacher Demo, p 313
- 1 mol of each of several different substances
- 1 sealed container per sample

Class Activity, p 314
- display from the Teacher Demo on p 313

Teacher Demo, p 321
- 50 g dry ice
- towel
- hammer
- large plastic bag
- duct tape
- tongs
- beaker
- balance

Class Activity, p 330
- 3 red marbles
- 6 green marbles
- 3 black marbles
- 12 blue marbles

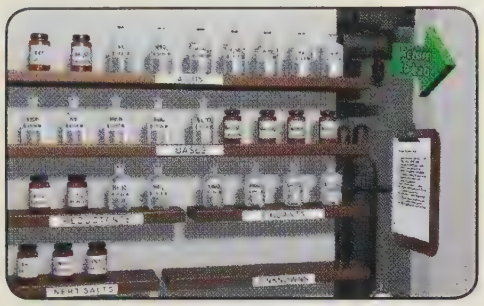
Online Teacher's Edition
10.2 Virtual Chem Lab 3: Counting by Measuring Mass



What's Online

CHEM TUTOR Students access guided step-by-step tutorials for solving various calculations involving moles.

ONLINE PROBLEMS Students can practice key problem-solving skills in an online problem set.

MATH HELP Identify the students who struggle with math by assigning an online math skills diagnostic test. These students can then improve and practice math skills using the MathXL tutorial system.

VIRTUAL LAB Students go on an animated virtual lab tour in which chemical quantities are studied in a simulated laboratory environment.

KINETIC ART Students watch animations of selected figures from the chapter followed by questions to check for understanding.

CONCEPTS IN ACTION Students watch an overview of a key chapter concept using real-world contexts and concrete examples and analogies. Each activity includes an interactive animation followed by analysis questions.

IN ACADEMIC STANDARDS for SCIENCE

Nature of Science

- Apply standard techniques in laboratory investigations to measure physical quantities in appropriate units and convert known quantities to other units as necessary.

Standard 4: Reactions and Stoichiometry

C.4.3 Use the mole concept to determine moles and number of atoms or molecules in samples of elements and compounds, given mass of the sample.

C.4.7 Perform calculations based on percent composition by mass of a compound or mixture when given the formula.

Focus on ELL

1 CONTENT AND LANGUAGE Clarify for students that the word *mole* has various common meanings and scientific meanings. The common meanings have several different origins, but the chemistry meaning is derived from the German word *molekulargewicht,* which means "molecular weight." In chemistry, a mole is a unit of measurement for particles of matter, such as atoms, molecules, and ions.

BEGINNING: LOW/HIGH Make a non-linguistic representation of the chemistry meaning of *mole* and present it to the class. Have students use a bilingual dictionary to find the definition of *mole*, and write the definition in their notebooks.

INTERMEDIATE: LOW/HIGH Ask students to brainstorm and write a list of other units of SI measures of matter.

ADVANCED: LOW/HIGH Predict the meaning of molar mass. Create an analogy between a grouping unit of measure, such as a pair or dozen, and a chemist's unit of measure, the mole.

BIG IDEA

THE MOLE AND QUANTIFYING MATTER

Essential Questions:

1. *Why is the mole an important measurement in chemistry?*
2. *How can the molecular formula of a compound be determined experimentally?*

CHEMYSTERY

A Formula for Cheating

Anabolic steroids are compounds that are developed to increase muscle size and strength. Stories are often in the news about professional athletes, such as baseball players, cyclists, and track stars, who have used steroids to enhance their performance.

More than 100 different types of anabolic steroids have been developed, and each of these substances is illegal in the United States without a prescription. Steroids have also been banned by many sports organizations because of their dangerous side effects and because they give the user an unfair advantage. Therefore, athletes are often tested for steroid use. So, how can the presence of steroids in the body be detected?

► Connect to the BIG IDEA As you read about the mole and chemical quantities, think about how the molar mass and molecular formula of a compound can be determined and used to identify the presence of steroids in the body.

Reactions and Stoichiometry C.4.3, C.4.7. See lessons for details.

Introduce the Chapter

IDENTIFYING PRECONCEPTIONS Students may not realize that quantifying particles of matter is even possible. Use this activity to introduce the idea of using mass to quantify large numbers of items.

Activity Divide students into groups and provide each group with a small cup, 15 pennies, 15 dimes, and access to a balance. Alternatively, students can use any two types of small items. Write the mass of a penny (2.500 g) and a dime (2.268 g) on the board. **Ask** How many pennies and dimes would a mass of 7.268 g indicate? *(2 pennies and 1 dime)* Give each group of students a cup with a mixture of pennies and dimes. Have them randomly remove some pennies and dimes and measure the total mass. Then have them count the coins and calculate the mass. Point out that in this chapter they will learn about a similar method, using molecular formulas, to calculate numbers of atoms in a substance.

UbD

Understanding by Design

Students are building toward measuring chemical quantities using the relationships of the mole and quantifying matter.

PERFORMANCE GOALS At the end of Chapter 10, students will be able to answer the essential questions by applying their knowledge of chemical quantities. Students will also be able to make calculations related to mole-mass, mole-volume, and percent composition relationships.

ESSENTIAL QUESTIONS Read the essential questions aloud. **Ask** When is it more convenient to count items in groups *(when you are working with large numbers of very small items)* **Ask** What information does a molecular formula tell you? *(the types of atoms and the ratio of each type in a compound)*

BIG IDEA Use the photo of baskets of blueberries to help students connect to the concepts they will learn in this chapter. Activate prior knowledge by asking whether they usually count berries individually or in groups. Point out that even a small basket holds a large number of blueberries. **Ask** How might grouping the blueberries make it easier to count them? *(grouping makes the number more manageable)*

CHEMYSTERY Have students read over the CHEMystery. Connect the CHEMystery to the Big Idea of The Mole and Quantifying Matter by discussing how a molecular formula helps quantify matter, or describe it using numbers. **Ask** What was the laboratory technician looking for in the urine? *(chemicals that indicated drug use)* As a hint to how the mystery could be solved, encourage students to think about what information the technician would be able to determine once the name of any chemical in the urine is known. *(the chemical formula)*

LESSON 10.1

Key Objectives

10.1.1 CONVERT among the count, mass, and volume of something.

10.1.2 EXPLAIN how chemists count the number of atoms, molecules, or formula units in a substance.

10.1.3 DETERMINE the molar mass of an element and of a compound.

C.4.3 The mole concept

CHEMISTRY & YOU

Q: *How can you quantify the amount of sand in a sand sculpture?* Have you ever gone to the beach and created a castle or sculpture out of sand? You could measure the amount of sand in a sculpture by counting the grains of sand. Is there an easier way to measure the amount of sand? Chemists measure the amount of a substance using a unit called the mole.

Key Questions

How can you convert among the count, mass, and volume of something?

How do chemists count the number of atoms, molecules, or formula units in a substance?

How do you determine the molar mass of an element and of a compound?

Vocabulary

- mole
- Avogadro's number
- representative particle
- molar mass

Measuring Matter

How can you convert among the count, mass, and volume of something?

Chemistry is a quantitative science. In your study of chemistry, you will analyze the composition of samples of matter and perform chemical calculations that relate quantities of the reactants in a chemical reaction to quantities of the products. To solve these and other problems, you will have to be able to measure the amount of matter you have.

One way to measure matter is to count how many of something you have. For example, you can count the mp3s in your collection. Another way to measure matter is to determine its mass. You can buy apples by the kilogram or pound, as shown in Figure 10.1. You can also measure matter by volume. For instance, people buy gasoline by the liter or the gallon.

Some of the units used for measuring indicate a specific number of items. For example, a pair always means two. A pair of shoes is two shoes, and a pair of aces is two aces. Similarly, a dozen always means 12. A dozen eggs is 12 eggs, and a dozen pens is 12 pens.

Apples can be measured in three different ways. At a fruit stand, they are often sold by the count. In a supermarket, you usually buy apples by weight or mass. At an orchard, you can buy apples by volume. Each of these different ways to measure apples can be equated to a dozen apples.

By count: 1 dozen apples = 12 apples

For average-sized apples, the following approximations can be used.

By mass: 1 dozen apples = 2.0 kg apples

By volume: 1 dozen apples = 0.20 bushel apples

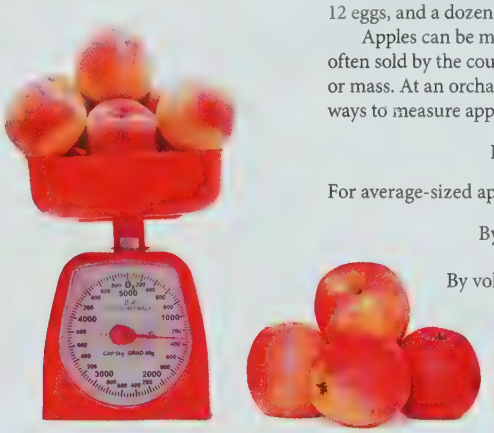

Figure 10.1 Measuring by Mass
A dozen apples has a mass of about 2.0 kg.

Focus on ELL

1 CONTENT AND LANGUAGE Review common conversion factors like feet to inches, meters to centimeters, hours to minutes, etc.

2 FRONTLOAD THE LESSON Ask students to share unique terms for grouped items from their native culture, and explain the quantity and size of the items in the group that each term represents. Distinguish between groupings in which the number of items varies and those with set numbers of items as a prelude to discussing Avogadro's number.

3 COMPREHENSIBLE INPUT Use a model to introduce the concept of molar mass. Display cartons of small, medium, large, and extra-large eggs as representations of moles of different elements. Tell students to think of the eggs as atoms, with each size being a different element. Explain that one carton of small eggs contains the same number of eggs as a carton of extra-large eggs, but the two cartons of eggs each have different masses because their individual eggs are different sizes (and masses).

Knowing how the count, mass, and volume of an item relate to a common unit allows you to convert among these units. For example, based on the unit relationships given on the previous page, you could calculate the mass of a bushel of apples or the mass of 90 average-sized apples using conversion factors such as the following:

$$\frac{1 \text{ dozen apples}}{12 \text{ apples}} \qquad \frac{2.0 \text{ kg apples}}{1 \text{ dozen apples}} \qquad \frac{1 \text{ dozen apples}}{0.20 \text{ bushel apples}}$$

SampleProblem 10.1

Finding Mass From a Count

What is the mass of 90 average-sized apples if 1 dozen of the apples has a mass of 2.0 kg?

KNOWNS
number of apples = 90 apples
12 apples = 1 dozen apples
1 dozen apples = 2.0 kg apples

UNKNOWN
mass of 90 apples = ? kg

1 Analyze **List the knowns and the unknown.** Use dimensional analysis to convert the number of apples to the mass of apples.

2 Calculate **Solve for the unknown.**

First, identify the sequence of conversions needed to perform the calculation. → number of apples ⟶ dozens of apples ⟶ mass of apples

Write the conversion factor to convert from number of apples to dozens of apples. → $\frac{1 \text{ dozen apples}}{12 \text{ apples}}$

Write the conversion factor to convert from dozens of apples to mass of apples. → $\frac{2.0 \text{ kg apples}}{1 \text{ dozen apples}}$

The units apples and dozen apples cancel, so the answer has the unit kg.

Multiply the number of apples by these two conversion factors to get the answer in kilograms.

$$90 \text{ apples} \times \frac{1 \text{ dozen apples}}{12 \text{ apples}} \times \frac{2.0 \text{ kg apples}}{1 \text{ dozen apples}} = 15 \text{ kg apples}$$

3 Evaluate **Does the result make sense?** A dozen apples has a mass of 2.0 kg, and 90 apples is less than 10 dozen apples, so the mass should be less than 20 kg of apples (10 dozen × 2.0 kg/dozen).

1. If 0.20 bushel is 1 dozen apples and a dozen apples has a mass of 2.0 kg, what is the mass of 0.50 bushel of apples?

2. Assume 2.0 kg of apples is 1 dozen and that each apple has 8 seeds. How many apple seeds are in 14 kg of apples?

In Problem 1, the desired conversion is bushels of apples ⟶ dozens of apples ⟶ mass of apples.

In Problem 2, the desired conversion is mass of apples ⟶ dozens of apples ⟶ number of apples ⟶ number of seeds.

Foundations for Math

WRITING CONVERSIONS Work thorough some conversions that students likely encounter in their daily lives. For example: If a recipe calls for six eggs, this quantity can be considered a half-dozen eggs: 6 eggs × (1 dozen/12 eggs) = 0.5 dozen.

As a class, write other familiar relationships, such as 3 feet = 1 yard, 50 cents = ½ dollar, 60 min = 1 h, 30 min = ½ h, etc. Point out that these equalities can be written in either direction, so 60 min = 1 h can also be written as 1 h = 60 min.

In **Sample Problem 10.1,** the mass of a large number of apples is determined by using the mass of a smaller number of apples by means of a conversion factor created from the subset of apples. (Note that, for this example, the mass of one dozen apples is an approximation. In reality, the masses of similar-sized apples vary from one apple to the next.)

Foundations for Reading

BUILD VOCABULARY Have students write two or three sentences, each of which relates a mole to at least one other vocabulary term, such as: a mole contains Avogadro's number of particles; the mass of one mole of a substance is its molar mass, which is found by determining the mass in grams of its representative particles.

READING STRATEGY Students may more easily grasp the meaning of the mole by developing their own mental picture. For instance, suggest visualizing a giant egg carton with 6.02×10^{23} depressions for particles, or a giant sack bulging with Avogadro's number of particles.

Explain

Measuring Matter

USE MODELS Pass around numerous bags, each of which contains a multiple of 12 beans. **Ask** How can you express the quantities of beans in the bags? *(Sample answers: You can count, weigh, or find the volume of the beans.)* Discuss how the word "dozen" can be used as a unit for the quantity of beans in each bag.

START A CONVERSATION Remind students that mass is a measure of the amount of matter that an object contains. **Ask** How are mass and weight related? *(Weight is a force that measures the pull of gravity on a given mass.)*

Sample Practice Problem

Assume 1 dozen oranges has a mass of 1.5 kg and that there are 14 orange slices in each orange. How many slices are in 6 kg of oranges? *(672 slices)*

Answers

1. 0.50 bushel × (1 dozen/0.20 bushel) × (2.0 kg/1 dozen) = 5.0 kg
2. 14 kg × (1 dozen/2.0 kg) × (12 apples/1 dozen) × (8 seeds/1 apple) = 670 seeds

Explain

What Is a Mole?

USE VISUALS Read aloud the caption to Figure 10.2. Then have the class read the text that discusses the number of particles in a mole. Guide students to understand that a mole represents a number of items just as *dozen, gross,* and *ream* all represent a quantity of items. **Ask** If you are counting the number of an extremely small item, should the number of items in a unit be small or large? *(For a small item, a large number per counting unit is more convenient.)* **Ask** How does your answer apply to a mole? *(A mole = 6.02 × 10^{23} items and is used to measure extremely small objects.)*

CHEMISTRY & YOU You could measure the mass of 1 grain of sand. Then you could measure the mass of the sand castle. If you divide the mass of the sand castle by the mass of 1 grain of sand, you can determine the total amount of sand in the castle.

MAKING CONNECTIONS Have students spend 2 minutes writing down what they remember about scientific notation and properties of exponents. As a class, share information and create a summary sheet of the important rules for these two concepts. Ask student volunteers to write several large numbers and small numbers on the board in standard form. Then use the summary sheet to guide students in rewriting the numbers using proper scientific notation. **Ask** When do you typically see measurements written in scientific notation? *(Sample answers: When a quantity is extremely small or extremely large, such as the diameter of a virus or distances in space.)* **Ask** How might scientific notation be useful in calculating the amount of atoms in a given number of moles? *(6.02 × 10^{23} is an extremely long number when it is not written in scientific notation.)*

Figure 10.2 Grouping Objects Words other than *mole* are used to describe a number of something—for example, a *dozen* eggs is 12 eggs.

CHEMISTRY & YOU

Q: *What are the different ways you can measure the amount of sand in a sand sculpture?*

What Is a Mole?

How do chemists count the number of atoms, molecules, or formula units in a substance?

Counting objects as big as apples is a reasonable way to measure how much of the object you have. Picture trying to count the grains of sand in a sand sculpture. It would be an endless job. Recall that matter is composed of atoms, molecules, and ions. These particles are much, much smaller than grains of sand, and an extremely large number of them are in a small sample of a substance. Obviously, counting particles one by one is not practical. However, think about counting eggs. It's easier when the eggs are grouped into dozens, as shown in Figure 10.2. A dozen is a specified number (12) of things.

Counting With Moles Chemists also use a unit that is a specified number of particles. The unit is called the mole. A **mole** (mol) of a substance is 6.02×10^{23} representative particles of that substance and is the SI unit for measuring the amount of a substance. The number of representative particles in a mole, 6.02×10^{23}, is called **Avogadro's number.** It was named in honor of the Italian scientist Amedeo Avogadro di Quaregna (1776–1856), who helped clarify the difference between atoms and molecules.

The term **representative particle** refers to the species present in a substance, usually atoms, molecules, or formula units. The representative particle of most elements is the atom. Iron is composed of iron atoms. Helium is composed of helium atoms. Seven elements, however, normally exist as diatomic molecules (H_2, N_2, O_2, F_2, Cl_2, Br_2, and I_2). The representative particle of these elements and of all molecular compounds is the molecule. The molecular compounds water (H_2O) and sulfur dioxide (SO_2) are composed of H_2O and SO_2 molecules, respectively. For ionic compounds, such as calcium chloride, the representative particle is the formula unit $CaCl_2$. **The mole allows chemists to count the number of representative particles in a substance.** A mole of any substance contains Avogadro's number of representative particles, or 6.02×10^{23} representative particles. Table 10.1 summarizes the relationship between representative particles and moles of substances.

Table 10.1

Representative Particles and Moles

Substance	Representative particle	Chemical formula	Representative particles in 1.00 mol
Copper	Atom	Cu	6.02×10^{23}
Atomic nitrogen	Atom	N	6.02×10^{23}
Nitrogen gas	Molecule	N_2	6.02×10^{23}
Water	Molecule	H_2O	6.02×10^{23}
Sucrose	Molecule	$C_{12}H_{22}O_{11}$	6.02×10^{23}
Calcium ion	Ion	Ca^{2+}	6.02×10^{23}
Calcium fluoride	Formula unit	CaF_2	6.02×10^{23}

Differentiated Instruction

ELL ENGLISH LANGUAGE LEARNERS Pair each student with limited English proficiency with a student who has strong mathematical skills. Encourage the English learners to ask their partners for help with any difficulty they are having understanding the terms and how to solve the problems.

L1 STRUGGLING STUDENTS Review the use of parentheses and the fraction bar as ways of grouping symbols to indicate the order of operations. Stress the importance of writing units for each measure in a calculation. Provide additional simple conversion problems for practice before students begin solving problems involving the mole.

L3 ADVANCED STUDENTS Have students create a clever way for their classmates to avoid confusing the concepts of mass and moles.

Converting Between Number of Particles and Moles The relationship, $1 \text{ mol} = 6.02 \times 10^{23}$ representative particles, is the basis for the following conversion factors that you can use to convert number of representative particles to moles and moles to number of representative particles.

$$\frac{1 \text{ mol}}{6.02 \times 10^{23} \text{ representative particles}} \quad \text{and} \quad \frac{6.02 \times 10^{23} \text{ representative particles}}{1 \text{ mol}}$$

Sample Problem 10.2

Converting Number of Atoms to Moles

Magnesium is a light metal used in the manufacture of aircraft, automobile wheels, and tools. How many moles of magnesium is 1.25×10^{23} atoms of magnesium?

KNOWN

number of atoms = 1.25×10^{23} atoms Mg

UNKNOWN

moles = ? mol Mg

1 Analyze **List the known and the unknown.**
The desired conversion is atoms ⟶ moles.

2 Calculate **Solve for the unknown.**

First, state the relationship between moles and number of representative particles.

$1 \text{ mol Mg} = 6.02 \times 10^{23} \text{ atoms Mg}$

Write the conversion factors you get based on this relationship.

$$\frac{1 \text{ mol Mg}}{6.02 \times 10^{23} \text{ atoms Mg}} \quad \text{and} \quad \frac{6.02 \times 10^{23} \text{ atoms Mg}}{1 \text{ mol Mg}}$$

Identify the conversion factor needed to convert from atoms to moles.

$$\frac{1 \text{ mol Mg}}{6.02 \times 10^{23} \text{ atoms Mg}}$$

Multiply the number of atoms of Mg by the conversion factor.

$$1.25 \times 10^{23} \text{ atoms Mg} \times \frac{1 \text{ mol Mg}}{6.02 \times 10^{23} \text{ atoms Mg}}$$

$$= 0.208 \text{ mol Mg}$$

3 Evaluate **Does the result make sense?** The given number of atoms (1.25×10^{23}) is less than one fourth of Avogadro's number (6.02×10^{23}), so the answer should be less than one fourth (0.25) mol of atoms. The answer should have three significant figures.

3. How many moles is 2.80×10^{24} atoms of silicon?

4. How many moles is 2.17×10^{23} representative particles of bromine?

Foundations for Math

DIVIDING POWERS OF 10 Tell students that the rules for dividing powers of 10 are the same as those for dividing variables with exponents: as long as the base is the same, you subtract the exponents. For example, $\frac{10^{27}}{10^{23}} = 10^{27-23} = 10^4$. Point out that each term is a power with the same base; caution students not to divide 10 by 10. In **Sample Problem 10.2** have students group the "like" numbers and divide accordingly: $\frac{1.25}{6.02} \times \frac{10^{23}}{10^{23}}$ Use a calculator to divide the decimal numbers and use the rules of exponents to divide the powers. In this case, $10^{23-23} = 10^0$, which is equal to 1.

Explain

APPLY CONCEPTS Explain that the mole is defined as the amount of substance that contains as many molecules or particles as there are atoms in 12 g of carbon-12 (^{12}C). Tell students that when the mole is used, the representative particles need to be specified as either atoms, molecules, ions, electrons, or formula units. Tell students to pay particular attention to the information given in a problem. Encourage students to underline or highlight the type of representative particle stated in a problem.

Sample Practice Problems

A. How many moles are equal to 3.61×10^{24} representative particles of potassium chloride, KCl? *(6.00 moles)*

B. About how many atoms are equal to 5.82×10^{23} atoms of tungsten (W)? *(0.967 moles)*

Extend

Connect to HISTORY Ask students to use the Internet to examine the history of the idea of chemical equivalency. Compare and contrast the ideas of the past with the modern accepted theory. Students should provide a timeline as well as the names of any noted scientists involved with this theory.

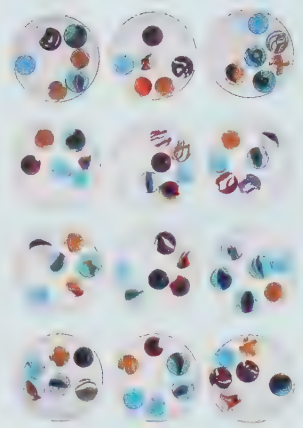
Answers

3. 2.80×10^{24} atoms Si × (1 mol/6.02×10^{23} atoms) = 4.65 mol Si

4. 2.17×10^{23} representative particles × (1 mol/6.02×10^{23} representative particles) = 0.360 mol Br_2

Explain

USE VISUALS Direct students' attention to Figure 10.3. Have students examine the photograph. Note that each cup contains six marbles. **Ask** How much would a dozen cups of marbles hold? *(72 marbles)* **Ask** What are some everyday items that come in a package containing more than one? *(Sample answers: tennis balls, 3; shoes, 2; batteries, 2, 4, 8)* Point out that a dozen packages of tennis balls would be three dozen tennis balls or 36 tennis balls. Point out that this idea can be applied to molecules. For example, a mole of water, H_2O, consists of 2 mol H atoms and 1 mol O atoms. Thus a mole of water contains $3 \times 6.02 \times 10^{23}$ atoms or 1.8×10^{24} atoms.



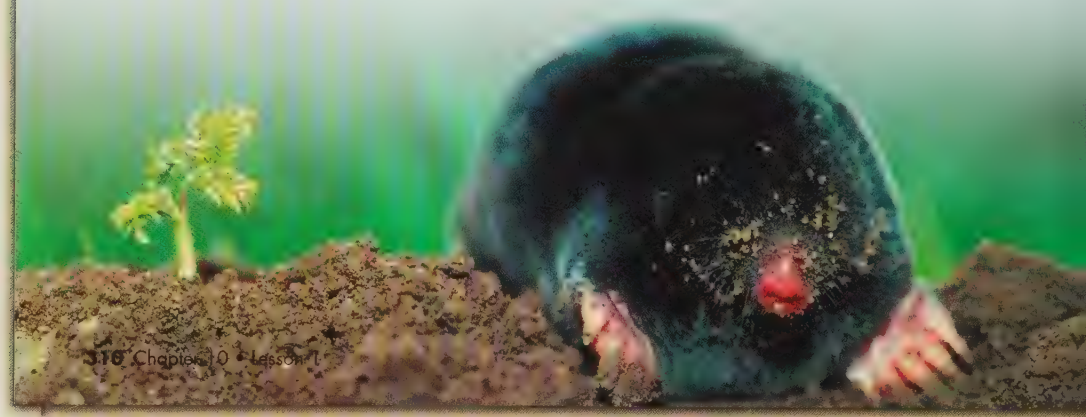


Figure 10.3 Counting Marbles
A dozen cups of marbles contain more than a dozen marbles. Similarly, a mole of molecules contains more than a mole of atoms.
Calculate ***How many atoms are in one mole of molecules if each molecule consists of six atoms?***

Suppose you want to determine how many atoms are in a mole of a compound. To do this, you must know how many atoms are in a representative particle of the compound. This number is determined from the chemical formula. Figure 10.3 illustrates this idea with marbles (atoms) in cups (molecules). The number of marbles in a dozen cups is (6×12), or 72 marbles. In the formula for carbon dioxide (CO_2), the subscripts show that one molecule of carbon dioxide is composed of three atoms: one carbon atom and two oxygen atoms. A mole of carbon dioxide contains Avogadro's number of CO_2 molecules. Each molecule contains three atoms, so a mole of carbon dioxide contains three times Avogadro's number of atoms. A molecule of carbon monoxide (CO) consists of two atoms, so a mole of carbon monoxide contains two times Avogadro's number of atoms.

To find the number of atoms in a given number of moles of a compound, you must first determine the number of representative particles. To convert the number of moles of a compound to the number of representative particles (molecules or formula units), multiply the number of moles by 6.02×10^{23} representative particles/1 mol. Then, multiply the number of representative particles by the number of atoms in each molecule or formula unit.

The Size of a Mole Perhaps you are wondering just how large a mole is. The SI unit, the mole, is not related to the small burrowing animal of the same name, shown in Figure 10.4. However, this little animal can help you appreciate the size of the number 6.02×10^{23}. Assume that an average animal-mole is 15 cm long, 5 cm tall, and has a mass of 145 g. Based on this information, the mass of 6.02×10^{23} animal-moles is 8.73×10^{22} kg. That means that the mass of Avogadro's number of animal-moles is equal to more than 60 times the combined mass of Earth's oceans. If spread over the entire surface of Earth, Avogadro's number of animal-moles would form a layer more than 8 million animal-moles thick. What about the length of 6.02×10^{23} animal-moles? If lined up end-to-end, 6.02×10^{23} animal-moles would stretch from Earth to the nearest star, Alpha Centauri, more than two million times. Are you beginning to understand how enormous Avogadro's number is?

Figure 10.4 A Mole of Moles
An average animal-mole has a mass of 145 g. The mass of 6.02×10^{23} animal-moles is 8.73×10^{22} kg.

UbD Check for Understanding

BIGIDEA Assess students' knowledge about the Big Idea of The Mole and Quantifying Matter by projecting Table 10.1 on an overhead. Ask students to briefly state why all the substances in the table have the same number of representative particles per mole. *(One mole of any type of substance is 6.02×10^{23} atoms, molecules, ions, formula units, etc. The type of particle does not affect the number of particles in one mole.)*

ADJUST INSTRUCTION If students are having difficulty with this concept, have them review the text preceding Table 10.1. Then repeat the activity.

Sample Problem 10.3

Converting Moles to Number of Atoms

Propane is a gas used for cooking and heating. How many atoms are in 2.12 mol of propane (C_3H_8)?

1 Analyze **List the knowns and the unknown.**

The desired conversion is moles ⟶ molecules ⟶ atoms.

KNOWNS

number of moles = 2.12 mol C_3H_8

1 mol C_3H_8 = 6.02×10^{23} molecules C_3H_8

1 molecule C_3H_8 = 11 atoms

(3 carbon atoms and 8 hydrogen atoms)

UNKNOWN

number of atoms = ? atoms

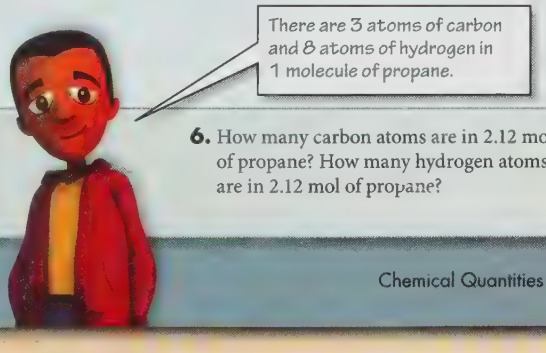
2 Calculate **Solve for the unknown.**

First, write the conversion factor to convert from moles to molecules.

$$\frac{6.02 \times 10^{23} \text{ molecules } C_3H_8}{1 \text{ mol } C_3H_8}$$

Remember to write the conversion factors so that the unit in the denominator cancels the unit in the numerator of the previous factor.

Write the conversion factor to convert from molecules to atoms.



$$\frac{11 \text{ atoms}}{1 \text{ molecule } C_3H_8}$$

Multiply the moles of C_3H_8 by the conversion factors.

$$2.12 \text{ mol } C_3H_8 \times \frac{6.02 \times 10^{23} \text{ molecules } C_3H_8}{1 \text{ mol } C_3H_8} \times \frac{11 \text{ atoms}}{1 \text{ molecule } C_3H_8}$$

$$= 1.40 \times 10^{25} \text{ atoms}$$

3 Evaluate **Does the result make sense?** There are 11 atoms in each molecule of propane and more than 2 mol of propane, so the answer should be more than 20 times Avogadro's number of propane molecules. The answer has three significant figures based on the three significant figures in the given measurement.

5. How many atoms are in 1.14 mol of sulfur trioxide (SO_3)?

6. How many carbon atoms are in 2.12 mol of propane? How many hydrogen atoms are in 2.12 mol of propane?

Foundations for Math

CONVERTING PRODUCTS TO SCIENTIFIC NOTATION Point out that if a calculation results in a product that has a power of 10, it may not necessarily be written in proper scientific notation. The coefficient must be a number greater than or equal to 1 and less than 10. Have students write a rule in their own words for converting products in which the coefficient is greater than 10, and in which the coefficient is less than 0. *(Move the decimal to the left and adjust the exponent up; Move the decimal to the right and adjust the exponent down.)*

In **Sample Problem 10.3**, students might opt to multiply 2.12, 6.02, and 11 together first, then multiply the result by 10^{23}. This would give an answer of 140×10^{23}, which is not in proper scientific notation. Point out that an additional conversion must be made by moving the decimal 2 places to the left and adjusting the exponent up by 2 to convert the answer to proper scientific notation.

Explain

CRITICAL THINKING Have students examine the problem solving process for Sample Problems 10.2 and 10.3. **Ask** Why do you divide by Avogadro's number in Sample Problem 10.2, but multiply by it in Sample Problem 10.3? *(In Sample Problem 10.2, the problem asks for the number of moles; in Sample Problem 10.3, the problem asks for the number of atoms.)* Have students write a note to themselves explaining when and how they should use this conversion factor. **Ask** Do the identities of the substances in the problems have any effect on the way you use Avogadro's number in the conversion process? *(no)* Why? *(The number of representative particles in a mole is a constant. The only information supplied by the substance is the number of atoms that makes up one representative particle of the substance. In Sample Problem 10.2, the representative particle is a single atom of Mg. In Sample Problem 10.3, the representative particle contains 11 atoms.)*

Misconception Alert

Some students may think they are finished when the calculator displays the result of the last calculation. Explain that not all calculators automatically convert the final answer to proper scientific notation, or use the proper number of significant figures. Make sure students know how to make the correct conversion to scientific notation with their particular calculator.

Sample Practice Problems

A. How many atoms are in 1.00 mole of glucose, $C_6H_{12}O_6$? *(1.44×10^{25} atoms)*

B. How many atoms of C are in 2.00 moles of $C_6H_{12}O_6$? *(7.22×10^{24} atoms)*

C. How many atoms of H are in 3.00 moles of $C_6H_{12}O_6$? *(2.17×10^{25} atoms)*

D. How many atoms of O are in 1.25 moles of $C_6H_{12}O_6$? *(4.52×10^{24} atoms)*

Answers

FIGURE 10.3 3.61×10^{24} atoms

5. 1.14 mol × (6.02×10^{23} molecules/mol) × (4 atoms/molecule) = 2.75×10^{24} atoms

6. 2.12 mol C_3H_6 × (6.02×10^{23} molecule/mol) × (3 atoms/molecule) = 3.83×10^{24} C atoms

2.12 mol C_3H_6 × (6.02×10^{23} molecule/mol) × (8 atoms/molecule) = 1.02×10^{25} H atoms

Explain

Molar Mass

USE MODELS Provide students with tactile counting objects to model the carbon and hydrogen relationship in Table 10.2. Guide students to use the objects to discover the mass ratio of carbon to hydrogen.

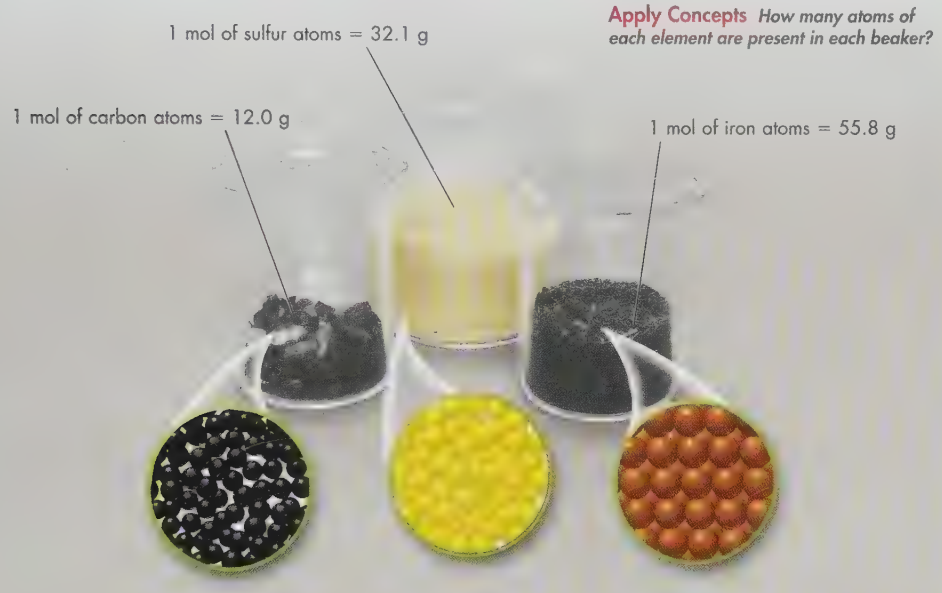
MAKING CONNECTIONS Point out that the mass of a single atom can be expressed in atomic mass units, but it is not realistic to work with single atoms. Explain that chemists work with large numbers of atoms for which the mass can be expressed in grams. In this text, the atomic masses are rounded to one place after the decimal point. Have students solve a given problem multiple times, using a different rounding rule each time, so they can see how rounding the atomic masses affects the answer.

APPLY CONCEPTS Explain that the molar masses of all elements contain the same number of atoms because the atomic masses of the elements are relative values. Present this idea by telling the class that the mass of an atom of element X is twice as great as the mass of an atom of element Y. **Ask** If you have 10 grams of element X and 10 grams of element Y, would you expect both samples to contain the same number of atoms? Why? *(No, because atoms of element X are twice as massive as atoms of element Y. The sample of X would contain only half as many atoms as the sample of Y.)* **Ask** What would you have to do to get the same number of atoms in both samples? *(Double the mass of element X so that it is twice the mass of element Y.)*

Interpret Data

Carbon Atoms		Hydrogen Atoms		Mass Ratio
Number	Mass (amu)	Number	Mass (amu)	$\frac{\text{Mass carbon}}{\text{Mass hydrogen}}$
●	12	•	1	$\frac{12\text{ amu}}{1\text{ amu}} = \frac{12}{1}$
●●	24 (2 × 12)	••	2 (2 × 1)	$\frac{24\text{ amu}}{2\text{ amu}} = \frac{12}{1}$
●●●●●	120 (10 × 12)	•••••	10 (10 × 1)	$\frac{120\text{ amu}}{10\text{ amu}} = \frac{12}{1}$
●●●●

The Mass of a Mole of an Element Quantities measured in grams are convenient for working in the laboratory, so chemists have converted the relative scale of masses of the elements in amu to a relative scale of masses in grams. **The atomic mass of an element expressed in grams is the mass of a mole of the element.** The mass of a mole of an element is its **molar mass.** For carbon, the molar mass is 12.0 g. For atomic hydrogen, the molar mass is 1.0 g. Figure 10.5 shows one mole of carbon, sulfur, and iron. Compare the molar masses in the figure to the atomic masses in your periodic table. Notice that the molar masses are rounded off to one place after the decimal point. All the examples and problems in this text use molar masses that are rounded off in this way. If your teacher uses a different rounding rule for molar masses, your answers to problems may differ slightly from the answers given in the text.



If you were to compare 12.0 g of carbon atoms with 16.0 g of oxygen atoms, you would find they contain the same number of atoms. The molar masses of any two elements must contain the same number of atoms. How many atoms are contained in the molar mass of an element? You already know. The molar mass of any element contains 1 mol or 6.02×10^{23} atoms of that element.

The mole can now be further defined as the amount of substance that contains the same number of representative particles as the number of atoms in 12.0 g of carbon-12. You know that 12.0 g is the molar mass of carbon-12, so 12.0 g of carbon is 1 mol of carbon atoms. The same relationship applies to hydrogen: 1.0 g of hydrogen is 1 mol of hydrogen atoms. Similarly, 24.3 g is the molar mass of magnesium, so 1 mol of magnesium (or 6.02×10^{23} atoms of magnesium) has a mass of 24.3 g. Molar mass is the mass of 1 mol of atoms of any element.

READING SUPPORT

Build Comprehension: ***Analogies*** You can buy small, medium, and large eggs. The size of the eggs doesn't affect how many eggs are in one dozen. Similarly, the size of the representative particles doesn't affect how many are in one mole. ***Can you think of another analogy to show the relationship between moles and the size of representative particles?***

Figure 10.5 Molar Mass of an Element One mole of carbon, sulfur, and iron are shown.
Apply Concepts ***How many atoms of each element are present in each beaker?***

Differentiated Instruction

L1 SPECIAL NEEDS STUDENTS For the Teacher Demo, mark the levels of the filled containers with tape on the outside of the containers so that sight-impaired students can tell by handling the displays that moles of different substances occupy different volumes and have different masses.

ELL ENGLISH LANGUAGE LEARNERS The differences in the terms *mass*, *atomic mass*, *atomic mass unit*, and *molar mass* may be confusing to English learners. Have students compile a glossary in which they define each term in English and in their native language. Encourage students to then write the word meanings or synonyms on sticky notes to be placed in the text.

L1 STRUGGLING STUDENTS If students are having difficulty with multi-step problems, break the problem into simple parts. For instance, for Sample Problem 10.4, insert the following after the first sentence: *Part a: Find the number of grams of hydrogen in H_2O_2. Part b: Find the number of grams of oxygen in H_2O_2. Part c: Find the molar mass of H_2O_2.*

Explore

Teacher Demo

PURPOSE Students will observe the difference in the mass and volume of 1 mol of different substances.

MATERIALS 1 mol each of a variety of common chemicals, 1 sealed container per sample

PROCEDURE Place 1 mol of at least two substances from each of the following categories in containers and seal them: molecular compounds—sucrose, water, paradichlorobenzene; ionic compounds—cobalt(II) chloride, potassium hydroxide, potassium dichromate; elements—sulfur, iron, carbon, mercury. On each container, mark the mass of each substance. Point out that each container holds 1 mol of a substance, no matter whether the representative particles are molecules, formula units, or atoms.

EXPECTED OUTCOME Students observe that a mole of one substance has a different mass from a mole of another substance, even though the same number of representative particles, 6.02×10^{23}, are present.

Answers

INTERPRET DATA

a. mass of 50 carbon atoms = 600 amu, mass of 50 hydrogen atoms = 50 amu
b. 12/1
c. Yes, the mass ratio for carbon to hydrogen is 12 to 1.

READING SUPPORT Answers will vary. The size of the donuts doesn't affect how many are in one dozen.

FIGURE 10.5 6.02×10^{23} atoms

Explore

Class Activity

PURPOSE Students learn to calculate the molar mass of a compound.

MATERIALS the display prepared for the Teacher Demo on p. 313

PROCEDURE Select a compound and show students how to calculate the mass of 1 mol using the atomic masses of the constituent elements from the periodic table. Have them calculate the molar masses of other compounds in the display. Lead students to see they have determined the mass of 6.02×10^{23} representative particles.

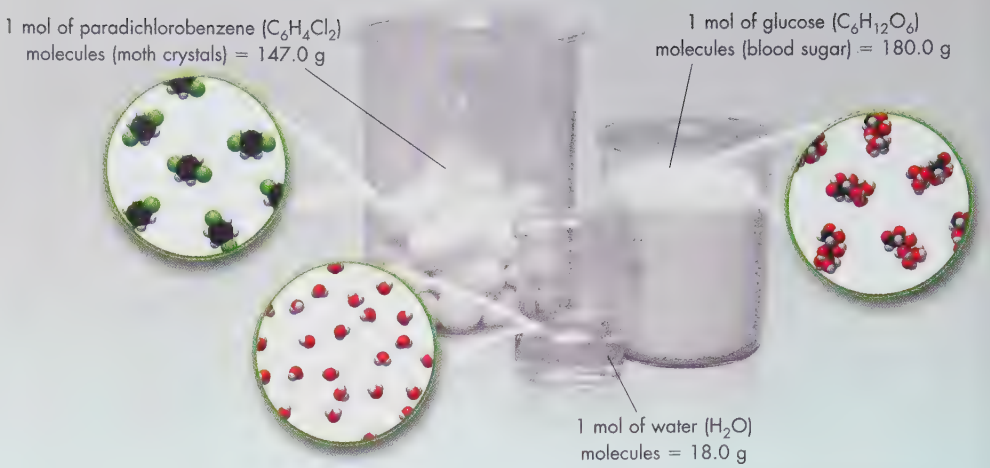


Figure 10.6 Molar Mass of a Compound
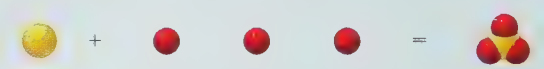
One mole is shown for each of three molecular compounds.
Infer *How do you know that each sample contains Avogadro's number of molecules?*



KINETIC ART *See the molar masses of compounds animated online.*

The Mass of a Mole of a Compound To find the mass of a mole of a compound, you must know the formula of the compound. The formula of sulfur trioxide is SO_3. A molecule of SO_3 is composed of one atom of sulfur and three atoms of oxygen.

1 SO_3 molecule = 1 S atom + 3 O atoms

You can calculate the mass of a molecule of SO_3 by adding the atomic masses of the atoms making up the molecule. From the periodic table, the atomic mass of sulfur (S) is 32.1 amu. The mass of three atoms of oxygen is three times the atomic mass of a single oxygen atom (O): 3×16.0 amu = 48.0 amu. So, the molecular mass of SO_3 is 32.1 amu + 48.0 amu = 80.1 amu.

1 S atom + 3 O atoms = 1 SO_3 molecule

32.1 amu + 16.0 amu + 16.0 amu + 16.0 amu = 80.1 amu

Now substitute the unit grams for atomic mass units to find the molar mass of SO_3. The molar mass (g/mol) of any compound is the mass in grams of 1 mol of that compound. Thus, 1 mol of SO_3 has a mass of 80.1 g. This is the mass of 6.02×10^{23} molecules of SO_3.

To calculate the molar mass of a compound, find the number of grams of each element in one mole of the compound. Then add the masses of the elements in the compound. This method for calculating molar mass applies to any compound, molecular or ionic. The molar masses of paradichlorobenzene ($C_6H_4Cl_2$, 147.0 g), water (H_2O, 18.0 g), and glucose ($C_6H_{12}O_6$, 180.0 g) in Figure 10.6 were obtained in this way.

UbD Check for Understanding

The Essential Question **Why is the mole an important measurement in chemistry?**

Assess students' knowledge about the mole by asking them write a one-minute response that answers this Essential Question. *(Sample answer: The mole is an important measurement in chemistry because it lets scientists turn a very large number into one that is small enough to use easily in calculations.)*

ADJUST INSTRUCTION If students are having trouble answering, have them re-read the sections What Is a Mole? and Molar Mass. Then allow them to revise their responses.

SampleProblem 10.4

Finding the Molar Mass of a Compound

The decomposition of hydrogen peroxide (H_2O_2) provides sufficient energy to launch a rocket. What is the molar mass of hydrogen peroxide?

KNOWNS

molecular formula = H_2O_2
mass of 1 mol H = 1.0 g H
mass of 1 mol O = 16.0 g O

UNKNOWN

molar mass = ? g/mol

1 Analyze **List the knowns and the unknown.** Convert moles of atoms to grams by using conversion factors (g/mol) based on the molar mass of each element. The sum of the masses of the elements is the molar mass.

2 Calculate **Solve for the unknown.**

Convert moles of hydrogen and oxygen to grams of hydrogen and oxygen.

$$2 \text{ mol H} \times \frac{1.0 \text{ g H}}{1 \text{ mol H}} = 2.0 \text{ g H}$$

$$2 \text{ mol O} \times \frac{16.0 \text{ g O}}{1 \text{ mol O}} = 32.0 \text{ g O}$$

One mole of H_2O_2 has 2 mol of H atoms and 2 mol of O atoms, so multiply the molar mass of each element by 2.

Add the results.

mass of 1 mol H_2O_2 = 2.0 g H + 32.0 g O = 34.0 g
molar mass of H_2O_2 = 34.0 g/mol

3 Evaluate **Does the result make sense?** The answer is the sum of two times the molar mass of hydrogen and oxygen (17.0 g/mol). The answer is expressed to the tenths place because the numbers being added are expressed to the tenths place.

7. Find the molar mass of PCl_3.

8. What is the mass of 1.00 mol of sodium hydrogen carbonate?

10.1 LessonCheck

9. Review What do you need to know to convert among the count, mass, and volume of something?

10. Describe How do chemists count the number of representative particles in a substance?

11. Explain How do you determine the molar mass of an element? How do you determine the molar mass of a compound?

12. Calculate If a dozen apples has a mass of 2.0 kg and 0.20 bushel is 1 dozen apples, how many bushels of apples are in 1.0 kg of apples?

13. Calculate How many moles is 1.50×10^{23} molecules of NH_3?

14. Calculate How many atoms are in 1.75 mol of $CHCl_3$?

15. Calculate What is the molar mass of $CaSO_4$?

Lesson Check Answers

9. You need a common unit.

10. Chemists use the mole to count the number of representative particles in a substance.

11. The molar mass of an element is the mass of a mole of the element. To calculate the molar mass of a compound, find the number of grams of each element in one mole of the compound. Then add the masses of the elements in the compound.

12. 0.10 bushel

13. 2.49×10^{-1} mol NH_3

14. 5.27×10^{24} atoms

15. 136.2 g/mol

Explain

Sample Practice Problems

A. Determine the mass of one mole of each of the following compounds: CO_2 *(44.0 g)*, SO_3 *(80.1 g)*, Br_2 *(159.8 g)*, H_2 *(2.0 g)*, N_2 *(28.0 g)*, NaOH *(40.0 g)*, $Al_2(SO_4)_3$ *(342.3 g)*, and $Ba(NO_3)_2$ *(261.3 g)*.

B. What is the mass, in grams, of 1.72 mol $CaCl_2$? *(191 g)*

Evaluate

Informal Assessment

Assess students' understanding of chemical quantities by writing the following three questions on the board and asking students to answer the questions quantitatively or qualitatively.

1. How many particles does one mole of any substance represent? *(6.02×10^{23} representative particles of that substance)*
2. How can you convert the number of atoms of any substance to moles? *(Multiply the number of atoms by the conversion factor 1 mole equals 6.02×10^{23} representative particles.)*
3. What is the molar mass of $Al_2(CO_3)_3$? *(234.0 g; also accept qualitative description of calculation)*

Then have students complete the 10.1 Lesson Check.

Reteach

Set up cooperative learning groups of three or four students with one student who is proficient in this topic. Have students review each sample problem in the lesson and create a list of parameters to follow for solving each type of question. Then provide the group with problems related to Lesson 10.1.

Answers

7. 1 mol P × (31.0 g P/1 mol P) = 31.0 g P
3 mol Cl × (35.5 g Cl/1 mol Cl)= 106.5 g Cl
31.0 g P + 106.5 g Cl = 138 g/mol

8. 1 mol Na × (23.0 g Na/1 mol Na) = 23.0 g Na
1 mol H × (1.0 g H/1 mol H) = 1.0 g H
1 mol C × (12.0 g C/1 mol C) = 12.0 g C
3 mol O ×(16.0 g O/1 mol O) = 48.0 g O
23.0 g Na + 1.0 g H + 12.0 g C + 48.0 g O = 84.0 g

CHEMISTRY & YOU Have students read the text and study the figures. Help students understand the nature of a mole by posing the following question: *Why is the statement "a mole of carbon has the same number of particles as a mole of carbon dioxide" true?* You may need to assist students in the following ways:

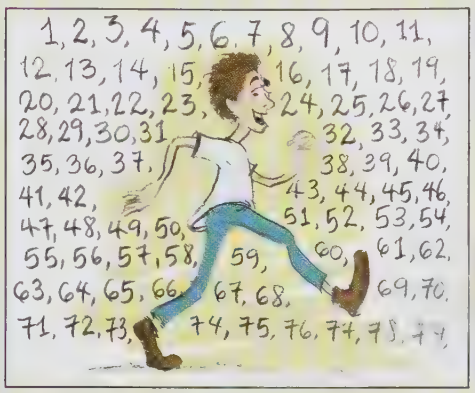
- The number of particles in a mole is independent of mass.
- A particle of a substance may be a single atom or many atoms joined by covalent bonds, or it may even be a subatomic particle.

Explain

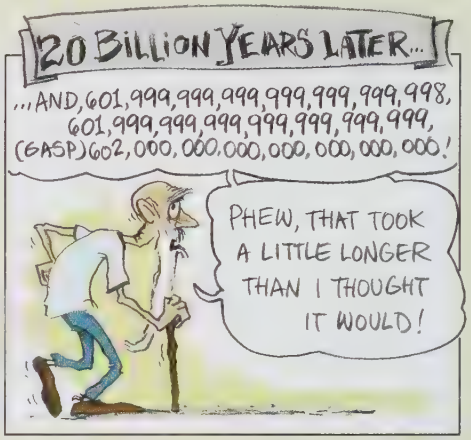
CRITICAL THINKING Students may wonder why a number such as a mole is used. Explain that there are certain numbers in science, called *fundamental constants*, each of which explains some property of nature. Challenge students to name other fundamental constants. Examples include the speed of light in a vacuum, $c = 3.00 \times 10^8$ m/s, and the elementary charge, $e = 1.602 \times 10^{-19}$ coulombs.

Answers

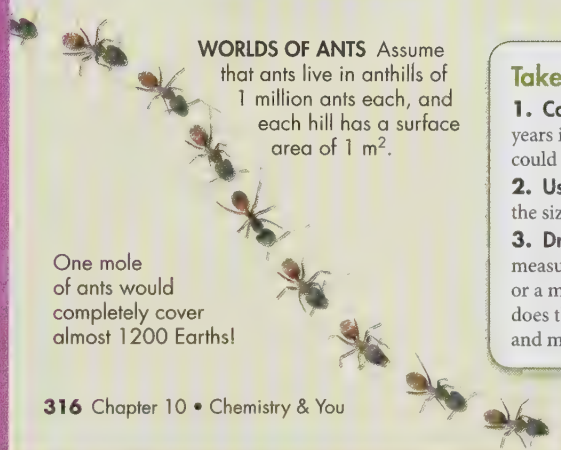
TAKE IT FURTHER



1. 6.02×10^{23} numbers/$(1 \times 10^6$ numbers/sec) = 6.02×10^{17} sec,
   6.02×10^{17} sec $\times$ (1year/3.15×10^7 sec) = 1.91×10^{10} years
2. Answers will vary but students should show the conversion factors in each calculation.
3. The masses of atoms and molecules are not all the same.



How Big Is a Mole?



The mole is an especially useful tool to chemists, because it allows them to express the number of representative particles of a substance in grams. For example, a 1 mol sample of carbon, which contains Avogadro's number of carbon atoms (6.02×10^{23}), has a mass of 12.0 g.

The mole is a huge quantity. Written out, Avogadro's number is 602,000,000,000,000,000,000,000. However, it may be difficult for you to comprehend exactly how big a mole is. Here are some interesting ways to visualize the size of a mole.

TOO BIG TO COUNT If you were able to count at the rate of 1 million numbers per second, it would take almost 20 billion years to count to 6.02×10^{23}.

WORLDS OF ANTS Assume that ants live in anthills of 1 million ants each, and each hill has a surface area of 1 m^2.

One mole of ants would completely cover almost 1200 Earths!

Take It Further

1. Calculate Show how to calculate the number of years it would take to count to Avogadro's number if you could count at the rate of 1 million numbers per second.

2. Use Models Develop your own concept to illustrate the size of Avogadro's number. Show your calculations.

3. Draw Conclusions At home, using a food scale, measure out a mole of table sugar (sucrose, $C_{12}H_{22}O_{11}$) or a mole of table salt (sodium chloride, NaCl). What does this measurement tell you about the size of atoms and molecules?

21st Century Skills To be successful in the 21st century, students need skills and learning experiences that extend beyond subject matter mastery. The following project helps students build these 21st Century Skills: *Critical Thinking and Problem Solving, Creativity and Innovation, Communication & Collaboration, Information Literacy, Initiative and Self-Direction, and Productivity and Accountability.*

MODELING THE MOLE Divide students into small groups of 4–6 students. Pose the following challenge to students. *An intermediate school teacher has requested your group's assistance in explaining the mole to her eighth grade science class, using a creative and entertaining five-minute animation or a computerized slide show with audio.* The presentation should include multiple examples and demonstrate step-by-step calculations that support the examples. Students should submit their presentations on CD or DVD-ROM.

10.2 Mole–Mass and Mole–Volume Relationships

C.4.3 The mole concept

CHEMISTRY & YOU

Q: *How can you calculate the moles of a substance in a given mass or volume?* Guess how many pennies are in the container and win a prize! You decide to enter the contest, and you win. You estimated the thickness and diameter of a penny to find its approximate volume. Then you estimated the dimensions of the container to obtain its volume. You did the arithmetic and made your guess. In a similar way, chemists use the relationships between the mole and quantities such as mass, volume, and number of particles to solve problems in chemistry.

Key Questions

How do you convert the mass of a substance to the number of moles of the substance?

How do you convert the volume of a gas at STP to the number of moles of the gas?

Vocabulary

- Avogadro's hypothesis
- standard temperature and pressure (STP)
- molar volume

The Mole–Mass Relationship

How do you convert the mass of a substance to the number of moles of the substance?

In the previous lesson, you learned that the molar mass of any substance is the mass in grams of one mole of that substance. This definition applies to all substances—elements, molecular compounds, and ionic compounds. In some situations, however, the term *molar mass* may be unclear. For example, suppose you were asked for the molar mass of oxygen. How you answer this question depends on what you assume to be the representative particle. If you assume the oxygen in the question is molecular oxygen (O_2), then the molar mass is 32.0 g/mol (2 × 16.0 g/mol). If you assume that the question is asking for the mass of a mole of oxygen atoms (O), then the answer is 16.0 g/mol. You can avoid confusion such as this by using the formula of the substance, in this case, O_2 or O.

Suppose you need a given number of moles of a substance for a laboratory experiment. How can you measure this amount? Suppose instead that you obtain a certain mass of a substance in a laboratory experiment. How many moles is this? **Use the molar mass of an element or compound to convert between the mass of a substance and the moles of the substance.** The conversion factors for these calculations are based on the relationship: molar mass = 1 mol.

$$\frac{\text{molar mass}}{1\ \text{mol}} \quad \text{and} \quad \frac{1\ \text{mol}}{\text{molar mass}}$$

Focus on ELL

1 CONTENT AND LANGUAGE Read aloud the key questions. Explain that the word *convert* in each question is the verb form of *conversion*. Encourage students to write their own definitions for the word *convert* and then to compare their definitions to the definition in a dictionary. Allow beginning speakers to use symbols or their native language for this activity if desired.

2 FRONTLOAD THE LESSON Place three 100 mL beakers on a table. Fill the first beaker with 50 ml of pennies. Repeat with the remaining beakers, using dimes for one and quarters for the other. Ask students to identify the similarities and differences of each beaker. Have them predict how this demonstration might relate to the topics in this lesson.

3 COMPREHENSIBLE INPUT Direct students to Figure 10.8 and read aloud the caption. Have students brainstorm, plan, and construct a model of the mole roadmap. Tell students that their models can help them solve problems.

LESSON 10.2

Key Objectives

10.2.1 DESCRIBE how to convert the mass of a substance to the number of moles of a substance, and moles to mass.

10.2.2 CONVERT the volume of a gas at STP to the number of moles of the gas.

Additional Resources

Reading and Study Workbook, Lesson 10.2

Available Online or on Digital Media:

- Teaching Resources, Lesson 10.2 Review
- Laboratory Manual, Lab 12
- Virtual Chemistry Laboratory Manual, Lab 3

PearsonChem.com

Engage

CHEMISTRY & YOU **Ask** What method, other than estimating the volume of each individual penny, might you use to determine the number of pennies present? *(Sample answer: Divide the total mass of all the pennies by the mass of one penny.)*

Activate Prior Knowledge

Review the mathematical conversions of moles to number of particles and number of particles to moles. Stress that using dimensional analysis in problem solving allows students to perform these calculations without having to memorize the process. Emphasize the use of writing units when solving problems.

IN ACADEMIC STANDARDS for SCIENCE

C.4.3 Use the mole concept to determine the number of moles and number of atoms or molecules in samples of elements and compounds, given mass of the sample.

Foundations for Reading

BUILD VOCABULARY Have students make a graphic organizer for this lesson by creating a KWL chart. In the first column, have students list what they know about each vocabulary term. In the second column, have them list what they want to know about each term. As they progress through the chapter, have them list in the third column what they learn about each term.

READING STRATEGY Instruct students to preview the key concepts, the section heads, the boldfaced items, the sample problems, and the figures. Have them write down a list of three things they expect to learn. After reading, have them state what they learned about each item they listed.

Explain

The Mole–Mass Relationship

MAKING CONNECTIONS Explain that in chemical manufacturing processes, reactants are purchased by mass, and products are sold by mass. However, point out that processes are set up and designed based on the ratio in which moles of reactants combine with each other to form moles of products. **Ask** If one mole of reactant produces one mole of product, predict how you can find the mass of product if you know the mass of the reactant. *(Convert the mass of reactant to number of moles. Then, convert that number of moles to the mass of product.)* Tell students that they will learn more about conversions such as this in Chapter 12.

Sample Practice Problem

Calculate the mass in grams for 0.750 mol of each of the following compounds:

a. cesium iodide (CsI) *(195 g)*

b. aluminum sulfate ($Al_2(SO_4)_3$) *(257 g)*

Sample Problem 10.5

Converting Moles to Mass

Items made out of aluminum, such as aircraft parts and cookware, are resistant to corrosion because the aluminum reacts with oxygen in the air to form a coating of aluminum oxide (Al_2O_3). This tough, resistant coating prevents any further corrosion. What is the mass, in grams, of 9.45 mol of aluminum oxide?

1 Analyze **List the known and the unknown.** The mass of the compound is calculated from the known number of moles of the compound. The desired conversion is moles ⟶ mass.

KNOWN

number of moles = 9.45 mol Al_2O_3

UNKNOWN

mass = ? g Al_2O_3

2 Calculate **Solve for the unknown.**

First, determine the mass of 1 mol of Al_2O_3.

$$2 \text{ mol Al} \times \frac{27.0 \text{ g Al}}{1 \text{ mol Al}} = 54.0 \text{ g Al}$$

$$3 \text{ mol O} \times \frac{16.0 \text{ g O}}{1 \text{ mol O}} = 48.0 \text{ g O}$$

$$1 \text{ mol } Al_2O_3 = 54.0 \text{ g Al} + 48.0 \text{ g O} = 102.0 \text{ g } Al_2O_3$$

Identify the conversion factor relating moles of Al_2O_3 to grams of Al_2O_3.

$$\frac{102.0 \text{ g } Al_2O_3}{1 \text{ mol } Al_2O_3}$$

Use the relationship: 1 mol Al_2O_3 = 102.0 g Al_2O_3.

Multiply the given quantity and molar by the conversion factor.

$$9.45 \text{ mol } Al_2O_3 \times \frac{102.0 \text{ g } Al_2O_3}{1 \text{ mol } Al_2O_3}$$

$$= 964 \text{ g } Al_2O_3$$

3 Evaluate **Does the result make sense?** The number of moles of Al_2O_3 is approximately 10, and each has a mass of approximately 100 g. The answer should be close to 1000 g. The answer has been rounded to the correct number of significant figures.

16. Find the mass, in grams, of 4.52×10^{-3} mol $C_{20}H_{42}$.

17. Calculate the mass, in grams, of 2.50 mol of iron(II) hydroxide.

Foundations for Math

SIGNIFICANT FIGURES Remind students that answers for calculations involving measurements should be written with the correct number of significant figures. Remind students that the following two rules apply:

1) Adding decimals: perform the operation, and then round the sum to match the measurement with the least number of decimal places.

2) Multiplying or dividing decimals: perform the operation, and then round the answer to match the measurement with the least number of significant figures.

In **Sample Problem 10.5,** the product of 9.45 × 102.0 = 963.9. Point out that the final answer is 964. The product is rounded to the nearest one because the calculation involved multiplication, and the multiplier with the least number of significant figures is 9.45. If necessary, have students refer to Chapter 3 for additional practice.

Sample Problem 10.6

Converting Mass to Moles

When iron is exposed to air, it corrodes to form red-brown rust. Rust is iron(III) oxide (Fe_2O_3). How many moles of iron(III) oxide are contained in 92.2 g of pure Fe_2O_3?

1 Analyze **List the known and the unknown.** The number of moles of the compound is calculated from the known mass of the compound. The conversion is mass ⟶ moles.

KNOWN

mass = 92.2 g Fe_2O_3

UNKNOWN

number of moles = ? mol Fe_2O_3

2 Calculate **Solve for the unknown.**

First, determine the mass of 1 mol of Fe_2O_3.

$$2 \text{ mol Fe} \times \frac{55.8 \text{ g Fe}}{1 \text{ mol Fe}} = 111.6 \text{ g Fe}$$

$$3 \text{ mol O} \times \frac{16.0 \text{ g O}}{1 \text{ mol O}} = 48.0 \text{ g O}$$

$$1 \text{ mol } Fe_2O_3 = 111.6 \text{ g Fe} + 48.0 \text{ g O} = 159.6 \text{ g } Fe_2O_3$$

Identify the conversion factor relating grams of Fe_2O_3 to moles of Fe_2O_3.

$$\frac{1 \text{ mol } Fe_2O_3}{159.6 \text{ g } Fe_2O_3}$$

Note that the known unit (g) is in the denominator and the unknown unit (mol) is in the numerator.

Multiply the given mass by the conversion factor.

$$92.2 \text{ g } Fe_2O_3 \times \frac{1 \text{ mol } Fe_2O_3}{159.6 \text{ g } Fe_2O_3}$$

$$= 0.578 \text{ mol } Fe_2O_3$$

3 Evaluate **Does the result make sense?** The given mass (about 90 g) is slightly larger than the mass of one-half mole of Fe_2O_3 (about 80 g), so the answer should be slightly larger than one-half (0.5) mol.

18. Find the number of moles in 3.70×10^{-1} g of boron.

19. Calculate the number of moles in 75.0 g of dinitrogen trioxide.

Foundations for Math

ROUNDING IN MULTI-STEP PROBLEMS Explain to students that when a problem involves multiple operations, they should avoid rounding until the final answer. When numbers are rounded in the middle step of a problem and then again at the final step of the problem, the result could be quite different from the correct answer, especially when dealing with larger quantities.

In **Sample Problem 10.6,** the first calculation yields a molar mass of 159.6. Some students may incorrectly assume that since division follows, they should round this mass to 160. Show students that premature rounding affects the accuracy of the final answer: 92.2/160 = 0.576. Explain why the answer of 0.578 is more accurate than 0.576.

Explain

Sample Practice Problem

Calculate the number of moles in 4.00×10^2 g of each of the following compounds.

a. cesium iodide *(1.54 mol)*

b. aluminum sulfate *(1.17 mol)*

CRITICAL THINKING Have students examine the problem-solving process for Sample Problems 10.5 and 10.6. Have students create a T-chart to compare and contrast the process for converting between moles to mass and mass to moles. Have students write a "caution" sticky note listing what to look for, what mistakes to avoid, and what process to follow in these types of problems. Tell students to place the sticky note in the text near these sample problems.

Misconception Alert

Students may not understand the difference between moles and mass. Explain that in the types of problems shown in Sample Problems 10.5 and 10.6, mass is typically given in grams. Moles is the unit of measurement for the number of representative particles. Clearly emphasize that mass is not equivalent to moles. Suggest that students create a spider chart to explore the relationship between the mole, mass, volume, and number of particles.

Answers

16. 4.52×10^{-3} mol $C_{20}H_{42}$ × (282.0 g $C_{20}H_{42}$/1 mol $C_{20}H_{42}$) = 1.27 g $C_{20}H_{42}$

17. 2.50 mol $Fe(OH)_2$ × (89.8 g $Fe(OH)_2$/1 mol $Fe(OH)_2$) = 225 g $Fe(OH)_2$

18. 3.70×10^{-1} g B × 0 (1 mol B/10.8 g B) = 3.43×10^{-2} mol B

19. 75.0 g N_2O_3 × (1 mol N_2O_3/76.0 g N_2O_3) = 0.987 mol N_2O_3

Explain

The Mole–Volume Relationship

START A CONVERSATION Ask students to name the unit that is used for the mass of a mole. *(grams per mole, g/mol)* **Ask** What unit is used for the volume of a mole? *(Liters per mole, L/mol)* Point out that, unlike solids and liquids, the molar volume of gases is predictable, but it can be affected by temperature and pressure. **Ask** How does temperature affect the volume of a gas? *(When temperature increases, volume increases. When temperature decreases, volume decreases.)* **Ask** How does pressure affect the volume of a gas? *(When pressure increases, volume decreases. A decrease in pressure causes an increase in volume.)* Emphasize that when comparing the molar volumes of gases, it is necessary to have the gases at the same conditions of temperature and pressure.

CHEMISTRY & YOU To calculate the moles of a substance, divide the mass of the substance by the mass of one mole of the substance. To calculate the moles of a gas in a given volume at STP, divide the volume by 22.4 L.

CHEMISTRY & YOU

Q: *How can you calculate the moles of a substance in a given mass? How can you calculate the moles of a gas in a given volume at STP?*

The Mole–Volume Relationship

How do you convert the volume of a gas at STP to the number of moles of the gas?

Look back at Figure 10.6. Notice that the volumes of one mole of different solid and liquid substances are not the same. For example, the volumes of one mole of glucose (blood sugar) and one mole of paradichlorobenzene (moth crystals) are much larger than the volume of one mole of liquid water. What about the volumes of gases? Unlike liquids and solids, the volumes of moles of gases, measured under the same physical conditions, are much more predictable. Why is this?

Avogadro's Hypothesis In 1811, Amedeo Avogadro proposed a groundbreaking explanation. **Avogadro's hypothesis** states that equal volumes of gases at the same temperature and pressure contain equal numbers of particles. The particles that make up different gases are not the same size. However, the particles in all gases are so far apart that a collection of relatively large particles does not require much more space than the same number of relatively small particles. Whether the particles are large or small, large expanses of space exist between individual particles of gas, as shown in Figure 10.7.

The volume of a gas varies with a change in temperature or a change in pressure. Due to these variations with temperature and pressure, the volume of a gas is usually measured at a standard temperature and pressure. **Standard temperature and pressure (STP)** means a temperature of 0°C and a pressure of 101.3 kPa, or 1 atmosphere (atm). At STP, 1 mol, or 6.02×10^{23} representative particles, of any gas occupies a volume of 22.4 L. The quantity, 22.4 L, is called the **molar volume** of a gas.

Calculating the Volume and Moles of a Gas at STP The molar volume of a gas at STP is a useful quantity to chemists. **The molar volume is used to convert between the number of moles of gas and the volume of the gas at STP.** The conversion factors for these calculations are based on the relationship 22.4 L = 1 mol at STP.

$$\frac{22.4\ \text{L}}{1\ \text{mol}} \quad \text{and} \quad \frac{1\ \text{mol}}{22.4\ \text{L}}$$

You can use these conversion factors to convert a known number of moles of gas to the volume of the gas at STP. Similarly, you can convert a known volume of gas at STP to the number of moles of the gas.

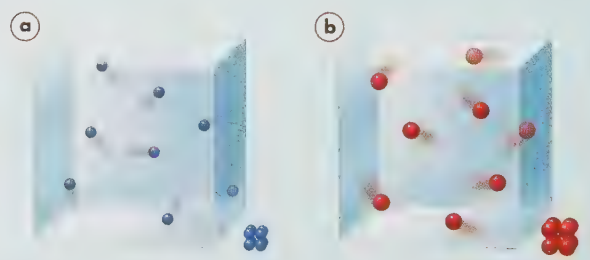


Figure 10.7 Volumes of Gases
In each container, the volume occupied by the gas molecules is small compared with the container's volume. **a.** The molecules in this container are small. **b.** This container can accommodate the same number of larger molecules.
Infer ***If the containers contained liquid molecules, and the molecules in container a were smaller than the molecules in container b, would both containers be able to accommodate the same number of molecules? Explain.***

Differentiated Instruction

LPR **LESS PROFICIENT READERS** Provide students with several problems and have them identify the known(s) and the unknown(s). Also have them look for key words, such as *total*, *difference*, and *larger*, that indicate operations or relationships.

L3 **ADVANCED STUDENTS** Have students apply their problem-solving skills to this question: Salvatore heated a mixture of potassium chlorate and manganese dioxide, producing 0.377 L of oxygen gas at STP. What was the mass of the gas collected? *(0.539 g)*

L1 **SPECIAL NEEDS STUDENTS** To help students with conversion problems, have them write each of the three pairs of conversion factors in Figure 10.8 on the two sides of an index card. Then have students create individual cards with each of the units of the known and unknown quantities: *grams, moles, liters,* and *representative particles*. Students can use the cards to model a problem as a method of testing their choices of conversion factors before solving the problem.

Sample Problem 10.7

Calculating Gas Quantities at STP

Sulfur dioxide (SO_2) is a gas produced by burning coal. It is an air pollutant and one of the causes of acid rain. Determine the volume, in liters, of 0.60 mol SO_2 gas at STP.

1 Analyze **List the knowns and the unknown.** Since SO_2 is a gas, the volume at STP can be calculated from the known number of moles.

KNOWNS

number of moles = 0.60 mol SO_2

1 mol SO_2 = 22.4 L SO_2 at STP

UNKNOWN

volume = ? L SO_2

2 Calculate **Solve for the unknown.**

First, identify the conversion factor relating moles of SO_2 to volume of SO_2 at STP.

$$\frac{22.4\ \text{L SO}_2}{1\ \text{mol SO}_2}$$

The following relationship applies for gases at STP: 22.4 L = 1 mol.

Multiply the given number of moles by the conversion factor.

$$0.60\ \text{mol SO}_2 \times \frac{22.4\ \text{L SO}_2}{1\ \text{mol SO}_2} = 13\ \text{L SO}_2$$

3 Evaluate **Does the result make sense?** One mole of any gas at STP has a volume of 22.4 L, so 0.60 mol should have a volume slightly larger than one half of a mole or 11.2 L. The answer should have two significant figures.

20. What is the volume of these gases at STP?

a. 3.20 × 10^{-3} mol CO_2

b. 3.70 mol N_2

c. 0.960 mol CH_4

21. At STP, how many moles are in these volumes of gases?

a. 67.2 L SO_2

b. 0.880 L He

c. 1.00 × 10^3 L C_2H_6

In Problem 20, convert from moles of gas to volume.

In Problem 21, convert from volume of gas to moles.

Foundations for Math

DIMENSIONAL ANALYSIS When solving problems using dimensional analysis, students sometimes lose track of their units. Remind students that writing the unknown at the beginning their equation can serve as an extra checkpoint to verify that the final units are the ones desired before taking the final step to solve the problem.

In **Sample Problem 10.7,** point out that "volume of SO_2" is written at the beginning of the equation. Because the units in the numerator of the final element on the right-hand side of the equation are "L SO_2," it is clear that the equation is properly arranged and can be completed.

Explore

Teacher Demo

PURPOSE Students will observe an approximation of molar volume.

MATERIALS Dry ice, towel, hammer, large plastic bag, duct tape, tongs, beaker, balance

PROCEDURE Wrap the dry ice in a towel and hit it with the hammer until it is in small pieces. Place 44 g (1 mol CO_2) of the small pieces in a beaker. Expel any air from the plastic bag, and tape the opening of the bag securely over the top of the beaker. As the dry ice sublimes, the bag will inflate.

SAFETY Wear goggles while crushing the dry ice, and do not allow dry ice to contact skin. Use tongs to handle the dry ice.

EXPECTED OUTCOMES The volume of gas produced will not equal 22.4 L because conditions are not standard. However, the volume will be close to this value.

Sample Practice Problem

At STP, what volume is occupied by each of the following gases?

a. 6.7 mol H_2 *(1.5 × 10^2 L H_2)*

b. 2.56 mol CH_4 *(5.73 × 10^1 L CH_4)*

Answers

FIGURE 10.7 No; container (a) would be able to accommodate more molecules than container (b).

20. **a.** 3.20 × 10^{-3} mol CO_2 × (22.4 L CO_2/1 mol CO_2) = 7.17 × 10^{-2} L CO_2

b. 3.70 mol N_2 × (22.4 L N_2/1 mol N_2) = 82.9 L N_2

c. 0.960 mol CH_4 × (22.4 L CH_4/1 mol CH_4) = 21.5 L CH_4

21. **a.** 67.2 L SO_2 × (1 mol SO_2/22.4 L SO_2) = 3.00 mol SO_2

b. 0.880 L He × (1 mol He/22.4 L He) = 0.039 mol He

c. 1.00 × 10^3 L C_2H_6 × (1 mol C_2H_6/22.4 L C_2H_6) = 44.6 mol C_2H_6

Explain

The Mole-Volume Relationship

APPLY CONCEPTS Review the concept of density as a ratio of mass to volume. Discuss the units of measure that correspond to density. *(g/mL, g/cm³, or g/L)* **Ask** If you had one mole of gas at STP, how could you calculate the density? *(Divide the number of grams of gas in one mole by 22.4 L.)* Emphasize that if the number of moles is given, the mass of the substance or the volume of a gas can be calculated. This concept will continue to be essential as students study mass–mass and other stoichiometric relationships in Chapter 12.

Sample Practice Problems

A. A gas has a density of 0.791 g/L. What is the molar mass of this gas? *(17.7 g/mol)*

B. What is the density of nitrogen gas at STP? *(1.25 g/L)*

Calculating Molar Mass and Density A gas-filled balloon will either sink or float in the air depending on whether the density of the gas inside the balloon is greater or less than the density of the surrounding air. Different gases have different densities. Usually the density of a gas is measured in grams per liter (g/L) and at a specific temperature. The density of a gas at STP and the molar volume at STP (22.4 L/mol) can be used to calculate the molar mass of the gas. Similarly, the molar mass of a gas and the molar volume at STP can be used to calculate the density of a gas at STP.

You have now examined a mole in terms of particles, mass, and volume of gases at STP. Figure 10.8 summarizes these relationships and illustrates the importance of the mole.

SampleProblem 10.8

Calculating the Molar Mass of a Gas at STP

The density of a gaseous compound containing carbon and oxygen is found to be 1.964 g/L at STP. What is the molar mass of the compound?

KNOWNS
density = 1.964 g/L
1 mol of gas at STP = 22.4 L

UNKNOWN
molar mass = ? g/mol

1 Analyze **List the knowns and the unknown.** The molar mass of the compound is calculated from the known density of the compound and the molar volume at STP.

2 Calculate **Solve for the unknown.**

First, identify the conversion factor needed to convert density to molar mass.

$$\frac{22.4\ \text{L}}{1\ \text{mol}}$$

Use the density and molar volume at STP to calculate the molar mass.

$$\text{molar mass} = \frac{\text{g}}{\text{mol}} = \frac{\text{g}}{\text{L}} \times \frac{22.4\ \text{L}}{1\ \text{mol}}$$

Multiply the given density by the conversion factor.

$$\frac{1.964\ \text{g}}{1\ \text{L}} \times \frac{22.4\ \text{L}}{1\ \text{mol}}$$

$$= 44.0\ \text{g/mol}$$

3 Evaluate **Does the result make sense?** The ratio of the calculated mass (44.0 g) to the volume (22.4 L) is about 2, which is close to the known density. The answer should have three significant figures.

22. A gaseous compound composed of sulfur and oxygen has a density of 3.58 g/L at STP. What is the molar mass of this gas?

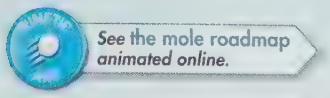
In Problem 22, use the density and molar volume of the gas at STP to calculate the molar mass.

23. What is the density of krypton gas at STP?

To do Problem 23, first find the molar mass of krypton. Use the molar mass and the molar volume at STP to calculate the density at STP.

Focus on ELL

4 LANGUAGE PRODUCTION Have students work in groups of four to complete the Small-Scale Lab on page 324. Make sure each group has ELLs of varied language proficiencies, so that more proficient students can help less proficient ones. Consider allowing students extra time to complete the Analyze section of the lab.



BEGINNING: LOW/HIGH Provide students with a chart to record their findings. Label the rows with the problem numbers from the Analyze and Conclude section of the lab.

INTERMEDIATE: LOW/HIGH Model the procedure for measuring the mass of sodium chloride for students. Have students mimic you to measure the mass for water and calcium carbonate.

ADVANCED: LOW/HIGH Have students assist students with lower English proficiencies with setting up the calculations and examining the results.

Figure 10.8 Mole Roadmap
The mole is at the center of your chemical calculations. To convert from one unit to another, you must use the mole as an intermediate step. The form of the conversion factor depends on what you know and what you want to calculate.

Interpret Diagrams *How many conversion factors are needed to convert from the mass of a gas to the volume of a gas at STP?*

10.2 LessonCheck

24. Describe How do you convert between the mass and the number of moles of a substance?

25. Describe How do you convert between the volume of a gas at STP and the number of moles of the gas?

26. Calculate How many grams are in 5.66 mol of $CaCO_3$?

27. Calculate Find the number of moles in 508 g of ethanol (C_2H_6O).

28. Calculate What is the volume, in liters, of 1.50 mol Cl_2 at STP?

29. Apply Concepts Three balloons filled with three different gaseous compounds each have a volume of 22.4 L at STP. Do these balloons have the same mass or contain the same number of molecules? Explain.

30. Calculate The density of an elemental gas is 1.7824 g/L at STP. What is the molar mass of the element?

31. Analyze Data The densities of gases A, B, and C at STP are 1.25 g/L, 2.86 g/L, and 0.714 g/L, respectively. Calculate the molar mass of each substance. Identify each substance as ammonia (NH_3), sulfur dioxide (SO_2), chlorine (Cl_2), nitrogen (N_2), or methane (CH_4).

BIG IDEA
THE MOLE AND QUANTIFYING MATTER

32. A chemist collects 2.94 L of carbon monoxide (CO) gas at STP during an experiment. Explain how she can determine the mass of gas that she collected. Why is the mole important for this calculation?

Lesson Check Answers

24. To convert mass to moles, multiply the given mass by 1 mol/molar mass. To convert moles to mass, multiply the given number of moles by molar mass/1 mol.

25. Divide the volume by 22.4 L.

26. 567 g $CaCO_3$

27. 11.0 mol C_2H_6O

28. 33.6 L Cl_2

29. The balloons have the same number of molecules. Each balloon is filled with one mole of gas, and one mole of any gas has the same number of molecules. The masses of the balloons will differ.

30. 39.9 g/mol

31. gas A: 28.0 g, nitrogen; gas B: 64.1 g, sulfur dioxide; gas C: 16.0 g, methane

32. BIG IDEA She needs to convert the volume of the gas to moles. Then she can covert moles to mass. She cannot determine mass without knowing moles.

Explain

The Mole Road Map

USE VISUALS Have students study Figure 10.8. Guide them through examples of the various mole conversions. For example, start with 50.0 g of a compound or element and convert it to moles, and then to particles. Then, start with a given volume of a gas and convert it to mass or particles. Have students recreate this roadmap in a visual way that helps them to clearly see the various relationships. Encourage students to use their visual as a reference when attempting homework problems.

Evaluate

Informal Assessment

Have students solve problems in which they use or explain the conversions for converting mass or volume to moles. Ask volunteers to come to the board to show their calculations. Have the class determine whether the calculations are correct. Then have students complete the 10.2 Lesson Check.

Reteach

Review the concept of density as a ratio of mass to volume. **Ask** If you know the molar volume of a gas, how could density help you determine the molar mass? *(Molar mass is the product of density and molar volume.)*

Answers

SAMPLE PROBLEM 10.8

22. 3.58 g/1 L × (22.4 L/1 mol) = 80.2 g/mol

23. 83.8 g/1 mol × (1 mol/22.4 L) = 3.74 g/L

FIGURE 10.8 You need to convert the mass of the gas to the moles of gas. Then convert moles to volume, so you need to use two conversion factors.

Small-Scale Lab

OBJECTIVE After completing this activity, students will be able to measure masses of chemicals and convert their data to moles and atoms. They will also be able to explore the quantitative chemical compositions of common substances.

SKILLS FOCUS measuring, calculating

PREP TIME 20 minutes

CLASS TIME 40 minutes

TEACHING TIPS Explore with students ways of finding the mass of liquid and solid samples so that the container does not interfere with the measurement. If time allows, have students repeat the procedure and average the data.

EXPECTED OUTCOME See data table.

ANALYZE AND CONCLUDE

Sample calculations using sample data:

1. See data table for answers.
2. See data table for answers.
3. 0.478 mol H × 6.02 × 10^{23} atoms/1 mol H = 2.88 10^{23} atoms H
4. water
5. water

YOU'RE THE CHEMIST

1. Sample answer: Find the mass of 100 drops of water, and then calculate the mass in grams per drop.
2. Sample answer: Find the mass of a piece of chalk. Write your name and find the mass of the chalk again. Convert the mass difference to moles and atoms.

FOR ENRICHMENT Have students use their results from the lab to calculate the volume of one mole of each substance tested. Then, have them use a balance to measure one mole of each substance and a graduated cylinder to find its volume. Have them compare the calculated and experimental values and discuss any discrepancies.

Small-Scale Lab

Counting by Measuring Mass

Purpose

To determine the mass of several samples of chemical compounds and use the data to count atoms

Materials

- H_2O, NaCl, and $CaCO_3$
- plastic spoon
- weighing paper
- balance

Procedure

Measure the mass of one level teaspoon of water (H_2O), sodium chloride (NaCl), and calcium carbonate ($CaCO_3$). Make a table similar to the one below.

	$H_2O(l)$	NaCl(s)	$CaCO_3(s)$
Mass (g)			
Molar mass (g/mol)			
Moles of each compound			
Moles of each element			
Atoms of each element			

Analyze and Conclude

1. Calculate Determine the number of moles of H_2O contained in one level teaspoon.

$$\text{moles of } H_2O = \text{g } H_2O \times \frac{1 \text{ mol } H_2O}{18.0 \text{ g } H_2O}$$

Repeat for the remaining compounds. Use the periodic table to calculate the molar masses of NaCl and $CaCO_3$.

2. Calculate Determine the number of moles of each element present in the teaspoon-sized sample of H_2O.

$$\text{moles of H} = \text{mol } H_2O \times \frac{2 \text{ mol H}}{1 \text{ mol } H_2O}$$

Repeat for the other compounds in your table.

3. Calculate Determine the number of atoms of each element present in the teaspoon-sized sample of H_2O.

$$\text{atoms of H} = \text{mol H} \times \frac{6.02 \times 10^{23} \text{ atoms H}}{1 \text{ mol H}}$$

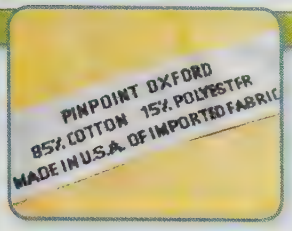
Repeat for the other compounds in your table.

4. Analyze Data Which of the three teaspoon-sized samples contains the greatest number of moles of molecules or formula units?

5. Analyze Data Which of the three compounds contains the greatest number of atoms?

You're the Chemist

1. Design an Experiment Can you count by measuring volume? Design and carry out an experiment to do it.



2. Design an Experiment Design an experiment that will determine the number of atoms of calcium, carbon, and oxygen it takes to write your name on the chalkboard with a piece of chalk. Assume chalk is 100 percent calcium carbonate, $CaCO_3$.

Sample Data

	$H_2O(l)$	NaCl(s)	$CaCO_3(s)$
Mass (g)	4.30	5.09	9.68
Molar mass (g/mol)	18.0	58.5	100.1
Moles of compound	0.239	0.0870	0.0967
Moles of elements	0.239 O 0.478 H	0.0870 Na 0.0870 Cl	0.0967 Ca 0.0967 C 0.290 O
Atoms of elements	1.44 × 10^{23} O 2.88 × 10^{23} H	5.24 × 10^{22} Na 5.24 × 10^{22} Cl	5.82 × 10^{22} Ca 5.82 × 10^{22} C 1.75 × 10^{22} O

10.3 Percent Composition and Chemical Formulas

C.4.3 The mole concept; C.4.7 Percent composition, empirical formulas, and molecular formulas

CHEMISTRY & YOU

Q: *What does the percent composition of a compound tell you?* A tag sewn into the seam of a shirt usually tells you what fibers were used to make the cloth and the percent of each. It helps to know the percents of the components in the shirt because they affect how warm the shirt is, whether it will need to be ironed, and how it should be cleaned. Similarly, in chemistry it is important to know the percents of the elements in a compound.

Key Questions

- ***How do you calculate the percent composition of a compound?***
- ***How can you calculate the empirical formula of a compound?***
- ***How does the molecular formula of a compound compare with the empirical formula?***

Vocabulary

- percent composition
- empirical formula

Percent Composition of a Compound

How do you calculate the percent composition of a compound?

In lawn care, the relative amount, or the percent, of each nutrient in fertilizer is important. In spring, you may use a fertilizer that has a high percent of nitrogen to "green" the grass. In fall, you may want to use a fertilizer with a higher percent of potassium to strengthen the root system. Knowing the relative amounts of the components of a mixture or compound is often useful.

The relative amounts of the elements in a compound are expressed as the **percent composition** or the percent by mass of each element in the compound. As shown in Figure 10.9, the percent composition of potassium chromate, K_2CrO_4, is K = 40.3%, Cr = 26.8%, and O = 32.9%. These percents must total 100% (40.3% + 26.8% + 32.9% = 100%). The percent composition of a compound is always the same.

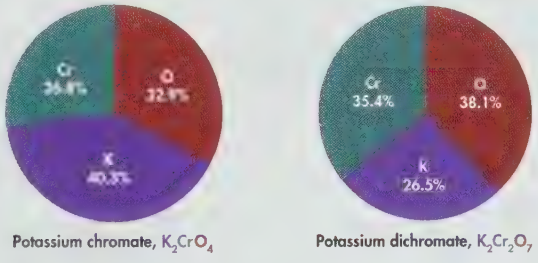


Figure 10.9 Percent Composition
Potassium chromate (K_2CrO_4) is composed of 40.3% potassium, 26.8% chromium, and 32.9% oxygen.
Compare ***How does this percent composition differ from the percent composition of potassium dichromate ($K_2Cr_2O_7$), a compound composed of the same three elements?***

Focus on ELL

1 CONTENT AND LANGUAGE Ask students if they have heard the word *composition* in their English class. Discuss the similarities and differences between the meaning of this word in English class versus the meaning in chemistry class.

2 FRONTLOAD THE LESSON As a class, determine the percentage of students in the room who are freshmen, sophomores, juniors, and seniors. Remind students that a percentage is determined by writing the part over the total and then multiplying by 100. Explain that they have calculated the percent composition of the class. Ask students to use what they learned from this activity to predict how the percent composition of a chemical compound is calculated.

3 COMPREHENSIBLE INPUT Explain Figure 10.9 and restate information in its caption as needed. Read the questions aloud, and provide students with a double bubble for them to write the similarities and differences between the two compounds.

LESSON 10.3

Key Objectives

10.3.1 CALCULATE the percent composition of a compound.

10.3.2 CALCULATE the empirical formula of a compound.

10.3.3 DISTINGUISH between empirical and molecular formulas.

Additional Resources

Reading and Study Workbook, Lesson 10.3

Available Online or on Digital Media:

- Teaching Resources, Lesson 10.3 Review, Interpreting Graphics
- Laboratory Manual, Lab 13
- Virtual Chemistry Laboratory Manual, Labs 25, 26, and 29

PearsonChem.com

Engage

CHEMISTRY & YOU Have students study the photograph. **Ask** What should be the total percent of materials listed on the label? *(100%)* **Ask** If the shirt were made of 25% polyester, instead of 15%, what percent of the shirt would be made of cotton? *(75%)*

Activate Prior Knowledge

Review the law of definite proportions and the concept of lowest whole-number ratios. Tell students to keep these concepts in mind as they proceed with the lesson.

IN ACADEMIC STANDARDS for SCIENCE

- Develop explanations based on reproducible data and observations gathered during laboratory investigations.
- Clearly communicate their ideas and results of investigations verbally and in written form using tables, graphs, diagrams, and photographs.
- Apply standard techniques in laboratory investigations to measure physical quantities in appropriate units and convert known quantities to other units as necessary.

Also covered C.4.3, C.4.7

Foundations for Reading

BUILD VOCABULARY Have students read the definition of *percent composition* above Figure 10.9 and have them define the term using the definitions of *percent* and *composition* in the dictionary. Have students use the same method to define *empirical formula*.

READING STRATEGY As they read the chapter, students should examine each visual as it is referenced in the text. Have them read each caption and answer any question.

Explain

Percent Composition of a Compound

USE VISUALS Have students study the circle graphs in Figure 10.9 and read the text on percent composition. Point out that the percentages given in the three sectors add up to a total of 100%. **Ask** Which compound is a better source of potassium? Why? *(K_2CrO_4, because it has a greater percentage of potassium than $K_2Cr_2O_7$).*

Sample Practice Problem

What is the percent composition of the compound formed when 2.72 g of potassium are combined with 2.48 grams of chlorine to form 5.20 grams of potassium chloride? *(52.4% K, 47.6% Cl)*

MAKE A CONNECTION Percents are used to show relative parts of mixtures as well as the composition of a compound. But when an extremely small amount of a substance is present in a large amount of another substance, it might not be practical to use percents (parts per one hundred) to show the makeup of the mixture. Instead, concentrations of extremely dilute solutions are sometimes measured in units of parts per million (ppm) or parts per billion (ppb). For example, the composition of a mixture that consists of 1 gram of a substance per 10^6 grams of water (or 1 milligram of substance per liter of water) can be expressed as 1 ppm.

Percent Composition From Mass Data If you know the relative masses of each element in a compound, you can calculate the percent composition of the compound. **The percent by mass of an element in a compound is the number of grams of the element divided by the mass in grams of the compound, multiplied by 100%.**

$$\%\text{ by mass of element} = \frac{\text{mass of element}}{\text{mass of compound}} \times 100\%$$

Sample Problem 10.9

Calculating Percent Composition From Mass Data

When a 13.60-g sample of a compound containing only magnesium and oxygen is decomposed, 5.40 g of oxygen is obtained. What is the percent composition of this compound?

1 Analyze **List the knowns and the unknowns.** The percent by mass of an element in a compound is the mass of that element divided by the mass of the compound multiplied by 100%.

KNOWNS
mass of compound = 13.60 g
mass of oxygen = 5.40 g O
mass of magnesium = 13.60 g − 5.40 g O = 8.20 g Mg

UNKNOWNS
percent by mass of Mg = ?% Mg
percent by mass of O = ?% O

2 Calculate **Solve for the unknowns.**

Determine the percent by mass of Mg in the compound.

$$\%\,Mg = \frac{\text{mass of Mg}}{\text{mass of compound}} \times 100\% = \frac{8.20\,g}{13.60\,g} \times 100\%$$
$$= 60.3\%\ Mg$$

Determine the percent by mass of O in the compound.

$$\%\,O = \frac{\text{mass of O}}{\text{mass of compound}} \times 100\% = \frac{5.40\,g}{13.60\,g} \times 100\%$$
$$= 39.7\%\ O$$

3 Evaluate **Does the result make sense?** The percents of the elements add up to 100%.
60.3% + 39.7% = 100%

33. A compound is formed when 9.03 g Mg combines completely with 3.48 g N. What is the percent composition of this compound?

34. When a 14.2-g sample of mercury(II) oxide is decomposed into its elements by heating, 13.2 g Hg is obtained. What is the percent composition of the compound?

Foundations for Math

PERCENTS Remind students that *percent* means "per 100." When you divide a part by a whole, the result is a decimal or fraction. If the result is written as a decimal, it can be converted to a percent by multiplying the decimal by 100. If the result is a fraction, such as ½, divide the numerator by the denominator to get a decimal. Then, multiply the decimal by 100. Note that the decimal is not multiplied by 100%, which has a decimal equivalent of 1 (100% = 100/100 = 1).

In **Sample Problem 10.9,** 8.2/13.6 = 0.6029 and 5.4/13.6 = 0.397. Convert these decimals to percents by multiplying each decimal by 100: 60.3%, 39.7%. Notice that 60.3% + 39.7% = 100%.

Percent Composition From the Chemical Formula You can also calculate the percent composition of a compound using its chemical formula. The subscripts in the formula are used to calculate the mass of each element in a mole of that compound. Using the individual masses of the elements and the molar mass, you can calculate the percent by mass of each element.

Learn more about percent composition *online.*

$$\%\ \text{by mass of element} = \frac{\text{mass of element in 1 mol compound}}{\text{molar mass of compound}} \times 100\%$$

SampleProblem 10.10

Calculating Percent Composition From a Formula

Propane (C_3H_8), the fuel commonly used in gas grills, is one of the compounds obtained from petroleum. Calculate the percent composition of propane.

KNOWNS

mass of C in 1 mol C_3H_8 = 3 mol × 12.0 g/mol = 36.0 g
mass of H in 1 mol C_3H_8 = 8 mol × 1.0 g/mol = 8.0 g
molar mass of C_3H_8 = 36.0 g/mol + 8.0 g/mol = 44.0 g/mol

UNKNOWNS

percent by mass of C = ?% C
percent by mass of H = ?% H

1 Analyze **List the knowns and the unknowns.** Calculate the percent by mass of each element by dividing the mass of that element in one mole of the compound by the molar mass of the compound and multiplying by 100%.

2 Calculate **Solve for the unknowns.**

Determine the percent by mass of C in C_3H_8

$$\%\,C = \frac{\text{mass of C in 1 mol } C_3H_8}{\text{molar mass of } C_3H_8} \times 100\% = \frac{36.0\,g}{44.0\,g} \times 100\%$$

$$= 81.8\%\,C$$

Determine the percent by mass of H in C_3H_8

$$\%\,H = \frac{\text{mass of H in 1 mol } C_3H_8}{\text{molar mass of } C_3H_8} \times 100\% = \frac{8.0\,g}{44.0\,g} \times 100\%$$

$$= 18\%\,0$$

3 Evaluate **Does the result make sense?** The percents of the elements add up to 100% when the answers are expressed to two significant figures (82% + 18% = 100%).

35. Calculate the percent by mass of nitrogen in these fertilizers.
- **a.** NH_3
- **b.** NH_4NO_3

36. Calculate the percent composition of these compounds.
- **a.** ethane (C_2H_6)
- **b.** sodium hydrogen sulfate ($NaHSO_4$)

Foundations for Math

SUM OF THE PARTS Caution students against taking a shortcut when working percentage problems. Since the sum of the percents should be 100%, many students only calculate one of the percents and then simply subtract from 100%. Stress that students should calculate each percent individually and then find the sum to check their answer.

In **Sample Problem 10.10,** the sum of the percents is 100% after rounding both percents to two significant figures.

Sample Practice Problem

Determine the percent composition of the following oxides:

- **a.** Fe_2O_3 *(69.9% Fe, 30.1% O)*
- **b.** HgO *(92.6% Hg, 7.39% O)*
- **c.** Ag_2O *(93.1% Ag, 6.90% O)*
- **d.** Na_2O *(74.2% Na, 25.8% O)*

Extend

Challenge students to develop a spreadsheet that can calculate the percent composition of a chemical compound. Tell students they should consider how to manage the initial inputs, such as the chemical formula and the molar masses of each element in the formula, as well as the formulas needed to complete their final calculations. Encourage students to demonstrate and explain their spreadsheets to interested students.

Answers

FIGURE 10.9 The percent composition of $K_2Cr_2O_7$ is 26.5% K, 35.4% Cr, and 38.1% O.

33. Mass of compound = 9.03 g + 3.48 g = 12.51 g; (9.03 g Mg/12.51 g compound) × 100% = 72.2% Mg; (3.48 g N/12.51 g compound) × 100% = 27.8% N

34. Mass of O = 14.2 g – 13.2 g = 1.0 g O; (1.0 g O/14.2 g) × 100% = 7.0% O; (13.2 g Hg/14.2 g) × 100% = 93.0% Hg

35. **a.** (14.0 g N/17.0 g) × 100% = 82.4% N
b. (28.0 g N/80.0 g) × 100% = 35.0% N

36. **a.** (24.0 g C/30.0 g) × 100% = 80.0% C
(6.00 g H/30.0 g) × 100% = 20.0% H
b. (23.0 g Na/120.1 g) × 100% = 19.2% Na
(1.0 g H/120.1 g) × 100% = 0.83% H
(32.1 g S/120.1 g) × 100% = 26.7% S
(64.0 g O/120.1 g) × 100% = 53.3% O

Explore

QuickLab

OBJECTIVE After completing this activity, students will be able to determine the percent of water in a hydrate.

SKILLS FOCUS observing, calculating

PREP TIME 20 minutes

CLASS TIME 30 minutes

SAFETY Students should wear safety goggles and tie back loose hair. Caution students that while heating test tubes, they should not aim the opening of the tube toward anyone. Tell them to move the test tube in the flame and not to heat one spot excessively. CAUTION! Be sure that students allow the tubes to cool completely before they touch them. Hot glass looks exactly like cold glass!

TEACHING TIPS For best results, students should do a second heating and cooling of each sample to determine whether all of the water has been driven off.

EXPECTED OUTCOME See the data table at the bottom of the page.

ANALYZE AND CONCLUDE

1–3. See the data table.

4. The hydrated salt of sodium sulfate lost the greatest percent. The hydrated salt of calcium chloride lost the smallest percent.

FOR ENRICHMENT Have students design and conduct a similar experiment to determine the percent of oxygen in potassium chlorate. Tell students that when potassium chlorate is heated, potassium chloride and oxygen are produced: $2KClO_3 \rightarrow 2KCl + 3O_2$. For classroom safety, no more than 5 g of potassium chlorate should be used. Results should show that potassium chlorate is approximately 39% oxygen.

QuickLab

Percent Composition

Purpose To measure the percent of water in a series of crystalline compounds called hydrates

Materials

- 3 medium-sized test tubes
- balance
- spatula
- hydrated compounds of copper(II) sulfate, calcium chloride, and sodium sulfate
- test tube holder
- gas burner

Procedure

1. Label each test tube with the name of a compound. Measure and record the masses.

2. Add 2–3 g of each compound (a good-sized spatula full) to the appropriately labeled test tube. Measure and record the mass of each test tube and the compound.

3. Using a test tube holder, hold one of the tubes at a 45° angle and gently heat its contents over the burner, slowly passing it in and out of the flame. Note any change in the appearance of the solid compound.

4. As moisture begins to condense in the upper part of the test tube, gently heat the entire length of the tube. Continue heating until all of the moisture is driven from the tube. This process may take 2–3 minutes. Repeat Steps 3 and 4 for the other two tubes.

5. Allow each tube to cool. Then measure and record the mass of each test tube and the heated compound.

Analyze and Conclude

1. Organize Data Set up a data table so that you can subtract the mass of the empty tube from the mass of the compound and the test tube, both before and after heating.

2. Calculate Find the difference between the mass of each compound before and after heating. This difference represents the amount of water lost by the hydrated compound due to heating.

3. Calculate Determine the percent by mass of water lost by each compound.

4. Analyze Data Which compound lost the greatest percent by mass of water? Which compound lost the smallest percent by mass of water?

CHEMISTRY & YOU

Q: What information can you get from the percent composition of a compound?

Percent Composition as a Conversion Factor You can use percent composition to calculate the number of grams of any element in a specific mass of a compound. To do this, multiply the mass of the compound by a conversion factor based on the percent composition of the element in the compound. In Sample Problem 10.10, you found that propane is 81.8 percent carbon and 18 percent hydrogen. That means that in a 100-g sample of propane, you would have 81.8 g of carbon and 18 g of hydrogen. You can use the following conversion factors to solve for the mass of carbon or hydrogen contained in a specific amount of propane.

$$\frac{81.8\text{ g C}}{100\text{ g } C_3H_8} \quad \text{and} \quad \frac{18\text{ g H}}{100\text{ g } C_3H_8}$$

Sample Data

	$CuSO_4 \cdot 5H_2O$	$CaCl_2 \cdot H_2O$	$Na_2SO_4 \cdot 10H_2O$
Test tube + hydrate (before heating)	23.88 g	23.60 g	23.92 g
Empty test tube	21.19 g	21.25 g	21.17 g
Mass of hydrate	2.69 g	2.35 g	2.75 g
Test tube + salt (after heating)	22.88 g	23.07 g	22.71 g
Empty test tube	21.19 g	21.25 g	21.17 g
Mass of anhydrous salt	1.69 g	1.82 g	1.54 g
Mass of water lost	1.00 g	0.53 g	1.21 g
Percent water (experimental)	37.2%	22.6%	44.0%
Percent water (theoretical)	36.1%	24.5%	55.9%

SampleProblem 10.11

Calculating the Mass of an Element in a Compound Using Percent Composition

Calculate the mass of carbon and the mass of hydrogen in 82.0 g of propane (C_3H_8).

1 Analyze **List the known and the unknowns.**

Use the conversion factors based on the percent composition of propane to make the following conversions: grams C_3H_8 ⟶ grams C and grams C_3H_8 ⟶ grams H.

KNOWN
mass of C_3H_8 = 82.0 g

UNKNOWNS
mass of carbon = ? g C
mass of hydrogen = ? g H

2 Calculate **Solve for the unknowns.**

To calculate the mass of C, first write the conversion factor to convert from mass of C_3H_8 to mass of C.

$$\frac{81.8\ g\ C}{100\ g\ C_3H_8}$$

From Sample Problem 10.10, the percent by mass of C in C_3H_8 is 81.8%.

Multiply the mass of C_3H_8 by the conversion factor.

$$82.0\ g\ C_3H_8 \times \frac{81.8\ g\ C}{100\ g\ C_3H_8} = 67.1\ g\ C$$

To calculate the mass of H, first write the conversion factor to convert from mass of C_3H_8 to mass of H.

$$\frac{18\ g\ H}{100\ g\ C_3H_8}$$

From Sample Problem 10.10, the percent by mass of H in C_3H_8 is 18%.

Multiply the mass of C_3H_8 by the conversion factor.

$$82.0\ g\ C_3H_8 \times \frac{18\ g\ H}{100\ g\ C_3H_8} = 15\ g\ H$$

3 Evaluate **Does the result make sense?** The sum of the two masses equals 82 g, the sample size, to two significant figures (67 g C + 15 g H = 82 g C_3H_8).

37. Calculate the grams of nitrogen in 125 g of each fertilizer.
- **a.** NH_3
- **b.** NH_4NO_3

In Problem 37, use the percent composition you calculated for each compound in Problem 35.

38. Calculate the mass of hydrogen in each of the following compounds:
- **a.** 350 g ethane (C_2H_6)
- **b.** 20.2 g sodium hydrogen sulfate ($NaHSO_4$)

In Problem 38, use the percent composition you calculated for each compound in Problem 36.

Focus on ELL

4 LANGUAGE PRODUCTION Have students work in groups of four to complete the lab. Make sure each group has ELLs of varied language proficiencies, so that more proficient students can model the procedure for less proficient ones. Have students work collaboratively to create anchor charts with challenging words they encounter, along with their meanings

BEGINNING

LOW Model the steps of the procedures for students.

HIGH Paraphrase the steps of the procedure and break long steps into smaller ones.

INTERMEDIATE: LOW/HIGH Provide students with a chart they can use to record their observations and calculations.

ADVANCED: LOW/HIGH Have students assist students with lower English proficiencies with the Analyze and Conclude questions. Make sure students understand the academic vocabulary.

CHEMISTRY & YOU You can calculate the number of grams of any element in a specific mass of a compound.

Explain

Sample Practice Problem

Calculate the percent composition of H_2SO_4. Then calculate the masses of hydrogen, sulfur, and oxygen in 90.0 g of H_2SO_4. *(2.0% hydrogen, 32.7% sulfur, 65.3% oxygen; 1.8 grams hydrogen, 29.4 grams sulfur, 58.8 grams oxygen)*

Answers

37. **a.** 125 g NH_3 × (82.4 g N/100 g NH_3) = 103 g N
b. 125 g NH_4NO_3 × (35.0 g N/100 g NH_4NO_3) = 43.8 g N

38. **a.** 350 g C_2H_6 × (2.0 × 10^1 g H/100g C_2H_6) = 7.0 × 10^1 g H
b. 20.2 g $NaHSO_4$ × (0.83 g H /100 g $NaHSO_4$) = 0.17 g H

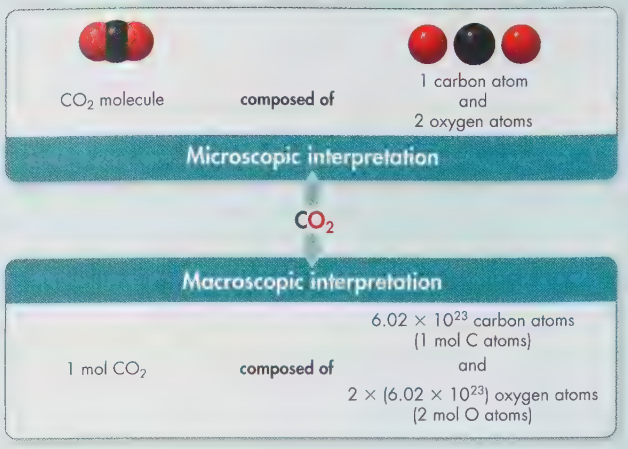
Empirical Formulas

Class Activity

PURPOSE Students are provided with an analogy that helps clarify the concepts of percent composition and empirical formulas.



MATERIALS 3 red marbles, 6 green marbles, 3 black marbles, and 12 blue marbles

PROCEDURE Provide pairs of students with sets of marbles. Have students express the number of different colored marbles as fractions and percents of the whole collection. **Ask** What percent of the collection do the red marbles represent? *(12.5%)* Show them that the sums of the fractions and percents are equal to 1 and 100%, respectively. **Ask** What is the ratio of red:green:black:blue marbles in lowest terms? *(1:2:1:4)*

This activity can be extended if the different colored marbles are assumed to be atoms of different elements. **Ask** What is the empirical formula of a hypothetical "compound" that consists of 25% red marbles and 75% green marbles? *(The ratio of red marbles to green marbles in the empirical formula would be 1:3.)*

EXPECTED OUTCOME Students express percent composition of the marbles and determine the "empirical formula" of a marble combination.

Figure 10.10 Interpreting Formulas
A formula can be interpreted on a microscopic level in terms of atoms or on a macroscopic level in terms of moles of atoms.

Empirical Formulas

How can you calculate the empirical formula of a compound?

A useful formula for cooking rice is to use one cup of rice and two cups of water. If you needed twice the amount of cooked rice, you would need two cups of rice and four cups of water. The formulas for some compounds also show a basic ratio of elements. Multiplying that ratio by any factor can produce the formulas for other compounds.

The **empirical formula** of a compound gives the lowest whole-number ratio of the atoms or moles of the elements in a compound. Figure 10.10 shows that empirical formulas may be interpreted at the microscopic (atomic) or macroscopic (molar) level. An empirical formula may or may not be the same as a molecular formula. For example, the lowest ratio of hydrogen to oxygen in hydrogen peroxide is 1:1. Thus the empirical formula of hydrogen peroxide is HO. The molecular formula of hydrogen peroxide, H_2O_2, has twice the number of atoms as the empirical formula. Notice that the ratio of hydrogen to oxygen is still the same, 1:1. The molecular formula tells the actual number of each kind of atom present in a molecule of the compound. For carbon dioxide, the empirical and molecular formulas are the same—CO_2. Figure 10.11 shows two compounds of carbon and hydrogen having the same empirical formula (CH) but different molecular formulas.

The percent composition of a compound can be used to calculate the empirical formula of that compound. The percent composition tells the ratio of masses of the elements in a compound. The ratio of masses can be changed to a ratio of moles by using conversion factors based on the molar mass of each element. The mole ratio is then reduced to the lowest whole-number ratio to obtain the empirical formula of the compound.

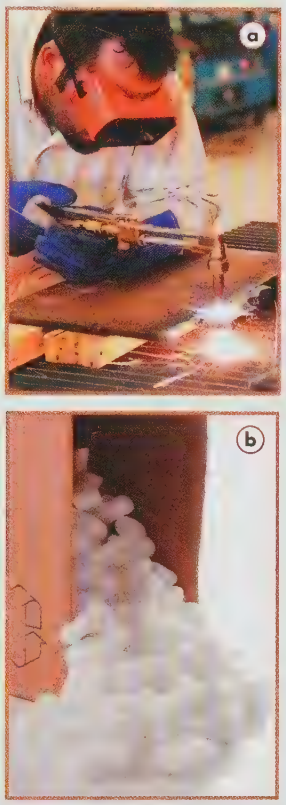


Figure 10.11 Compounds With the Same Empirical Formula
Two different compounds can have the same empirical formula. **a.** Ethyne (C_2H_2), also called acetylene, is a gas used in welders' torches. **b.** Styrene (C_8H_8) is used in making polystyrene.
Calculate *What is the empirical formula of ethyne and styrene?*

Differentiated Instruction

LPR LESS PROFICIENT READERS In small groups, have students develop numbered lists of steps to follow for determining empirical formulas from percent composition, determining empirical formulas from mass data, and determining molecular formulas from the empirical formula and molar mass.

L2 SPECIAL NEEDS STUDENTS For the class activity, consider replacing the colored marbles with larger tactile colored objects, larger tactile textured objects, or colored pieces of candy. Issues involving potential swallowing of the materials or sight impairment should be considered when selecting materials for the lab.

L3 ADVANCED STUDENTS Have students research the formulas of the three different oxides of iron. **Ask** Which of the oxides contains a higher percent of iron? *(Of FeO (77.7% Fe), Fe_2O_3 (69.9% Fe), and Fe_3O_4 (72.3% Fe), FeO has the highest percent of iron.)*

Sample Problem 10.12

Determining the Empirical Formula of a Compound

A compound is analyzed and found to contain 25.9% nitrogen and 74.1% oxygen. What is the empirical formula of the compound?

1 Analyze **List the knowns and the unknown.** The percent composition gives the ratio of the mass of nitrogen atoms to the mass of oxygen atoms in the compound. Change the ratio of masses to a ratio of moles and reduce this ratio to the lowest whole-number ratio.

KNOWNS

percent by mass of N = 25.9% N
percent by mass of O = 74.1% O

UNKNOWN

empirical formula = N_2O_5

2 Calculate **Solve for the unknown.**

Convert the percent by mass of each element to moles.

$$25.9\,\text{g N} \times \frac{1\ \text{mol N}}{14.0\,\text{g N}} = 1.85\ \text{mol N}$$

$$74.1\,\text{g O} \times \frac{1\ \text{mol O}}{16.0\,\text{g O}} = 4.63\ \text{mol O}$$

The mole ratio of N to O is $N_{1.85}O_{4.63}$.

Percent means "parts per 100," so 100.0 g of the compound contains 25.9 g N and 74.1 g O.

Divide each molar quantity by the smaller number of moles to get 1 mol for the element with the smaller number of moles.

$$\frac{1.85\ \text{mol N}}{1.85} = 1\ \text{mol N}$$

$$\frac{4.63\ \text{mol O}}{1.85} = 2.50\ \text{mol O}$$

The mole ratio of N to O is now $N_1O_{2.5}$.

Multiply each part of the ratio by the smallest whole number that will convert both subscripts to whole numbers.

1 mol N × 2 = 2 mol N
2.5 mol O × 2 = 5 mol O

The empirical formula is N_2O_5.

3 Evaluate **Does the result make sense?** The subscripts are whole numbers, and the percent composition of this empirical formula equals the percents given in the original problem.

39. Calculate the empirical formula of each compound.
- **a.** 94.1% O, 5.9% H
- **b.** 67.6% Hg, 10.8% S, 21.6% O

40. 1,6-diaminohexane is used to make nylon. What is the empirical formula of this compound if its percent composition is 62.1% C, 13.8% H, and 24.1% N?

Foundations for Math

EQUIVALENT RATIOS The subscripts in empirical formulas are always whole numbers, because compounds cannot have partial atoms. Show students that equivalent ratios can be used to rewrite decimals as whole numbers. To do this, multiply each part of the ratio by the smallest whole number that will convert both subscripts to whole numbers.

In **Sample Problem 10.12,** the ratio of moles of N to moles of O is 1 to 2.5. The smallest whole number to which 2.5 can be converted is 5, which is the product of 2.5 and 2. Because the moles of N and O must remain in the same ratio, the moles of N must also be multiplied by 2. Thus, $N_1O_{2.5}$ is equivalent to N_2O_5.

Explain

APPLY CONCEPTS Direct students to examine Sample Problem 10.12. Explain that when using percent composition to determine an empirical formula, 100.0 g of compound is often arbitrarily chosen because it is easy to use. If an element comprises 28.5% of the mass of a compound, for example, it makes up 28.5 g of a 100.0-g sample. Any other mass of compound can be used but computation will be more difficult.

Sample Practice Problem

What is the empirical formula of each of the following compounds?

- **a.** 36.1% Ca, 63.9% Cl *($CaCl_2$)*
- **b.** 40.0% C, 6.7% H, 53.3% O *(CH_2O)*

Molecular Formulas

CRITICAL THINKING Have students examine the patterns shown in Table 10.3. Then have them add entries for these pairs of compounds: nitrogen dioxide (NO_2) and dinitrogen tetroxide (N_2O_4), diphosphorus pentoxide (P_2O_5) and tetraphosphorus decoxide (P_4O_{10}). Instruct students to determine the empirical formula for each pair.

Extend

Connect to NUTRITION

Tell students that a variety of carbohydrates have the empirical formula CH_2O. Two such carbohydrates are glucose, which is abundant in plants and animals, and fructose, which is found in fruits and honey. Point out that glucose and fructose both share the same molecular formula: $C_6H_{12}O_6$. **Ask** Do you think these carbohydrates have the same structure? Why? *(No, because they have different names.)* **Ask** Do you think there are other carbohydrates with this molecular formula? *(Answers will vary.)* Challenge students to research and draw the structures of glucose and fructose, and list any additional carbohydrates that share the chemical formula $C_6H_{12}O_6$. Tell students they can learn more about these types of monosaccharides in Chapter 24.

Interpret Data

Comparison of Empirical and Molecular Formulas

Formula (name)	Classification of formula	Molar mass (g/mol)
CH	Empirical	13
C_2H_2 (ethyne)	Molecular	26 (2 × 13)
C_6H_6 (benzene)	Molecular	78 (6 × 13)
CH_2O (methanal)	Empirical and molecular	30
$C_2H_4O_2$ (ethanoic acid)	Molecular	60 (2 × 30)
$C_6H_{12}O_6$ (glucose)	Molecular	180 (6 × 30)

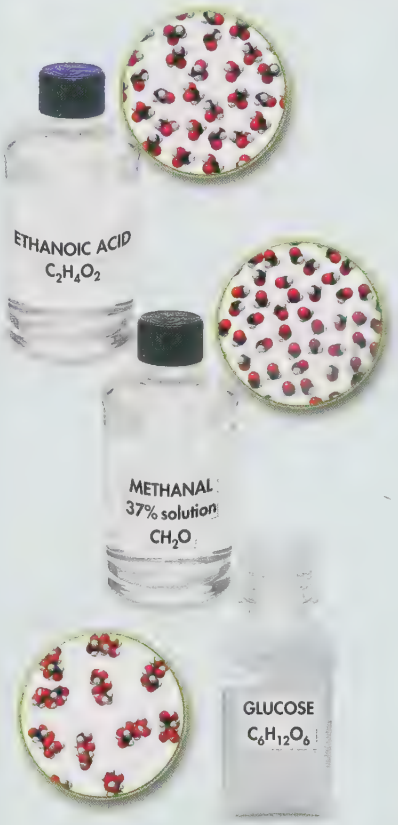

Table 10.3 Different compounds can have the same empirical formula.

a. Read Tables What is the molar mass of benzene, C_6H_6?

b. Interpret Tables Which compounds in the table have the empirical formula CH_2O?

c. Explain Why is the molar mass of glucose ($C_6H_{12}O_6$) equal to six times the molar mass of methanal (CH_2O)?

Hint: How is the formula $C_6H_{12}O_6$ related to the formula CH_2O?

Molecular Formulas

How does the molecular formula of a compound compare with the empirical formula?

Look at the compounds listed in Table 10.3. Ethyne and benzene have the same empirical formula—CH. Methanal, ethanoic acid, and glucose, shown in Figure 10.12, have the same empirical formula—CH_2O. Notice that the molar masses of the compounds in these two groups are simple whole-number multiples of the molar masses of the empirical formulas, CH and CH_2O. **The molecular formula of a compound is either the same as its experimentally determined empirical formula, or it is a simple whole-number multiple of its empirical formula.**

Once you have determined the empirical formula of a compound, you can determine its molecular formula, if you know the compound's molar mass. A chemist often uses an instrument called a mass spectrometer to determine molar mass. The compound is broken into charged fragments (ions) that travel through a magnetic field. The magnetic field deflects the particles from their straight-line paths. The mass of the compound is determined from the amount of deflection experienced by the particles.

You can calculate the empirical formula mass (efm) of a compound from its empirical formula. This is simply the molar mass of the empirical formula. Then you can divide the experimentally determined molar mass by the empirical formula mass. This quotient gives the number of empirical formula units in a molecule of the compound and is the multiplier to convert the empirical formula to the molecular formula.

Figure 10.12 Compounds With the Empirical Formula CH_2O
Methanal (formaldehyde), ethanoic acid (acetic acid), and glucose have the same empirical formula.
Apply Concepts ***How could you easily obtain the molar mass of ethanoic acid using the molar mass of methanal?***

UbD **Check for Understanding**

How does the molecular formula of a compound compare with the empirical formula?

Assess students' understanding of molecular and empirical formulas by asking them a series of true/false questions. Have students give a thumbs-up sign if the statement is true and a thumbs-down sign if the statement is false.

- Empirical and molecular formulas are never the same for any compound. *(false)*
- If you know the empirical formula of the compound, then you know the smallest whole-number ratio of the elements in that compound. *(true)*
- A ratio exists between the empirical formula and the molecular formula of a compound. *(true)*

ADJUST INSTRUCTION Instruct students to reread the text under Empirical Formulas and Molecular Formulas. In groups, have them write a compare and contrast table. Then restate the questions above, and have each group explain why the statement is true or false.

SampleProblem 10.13

Finding the Molecular Formula of a Compound

Calculate the molecular formula of a compound whose molar mass is 60.0 g/mol and empirical formula is CH_4N.

KNOWNS
empirical formula = CH_4N
molar mass = 60.0 g/mol

UNKNOWN
molecular formula = $C_2H_8N_2$

1 Analyze **List the knowns and the unknown.** Divide the molar mass by the empirical formula mass to obtain a whole number. Multiply the empirical formula subscripts by this value to get the molecular formula.

2 Calculate **Solve for the unknown.**

First, calculate the empirical formula mass.

$$\text{efm of } CH_4N = 12.0 \text{ g/mol} + 4(1.0 \text{ g/mol}) + 14.0 \text{ g/mol} = 30.0 \text{ g/mol}$$

Divide the molar mass by the empirical formula mass.

$$\frac{\text{molar mass}}{\text{efm}} = \frac{60.0 \text{ g/mol}}{30.0 \text{ g/mol}} = 2$$

Multiply the formula subscripts by this value.

$$(CH_4N) \times 2 = C_2H_8N_2$$

3 Evaluate **Does the result make sense?** The molecular formula has the molar mass of the compound.

41. What is the molecular formula of a compound with the empirical formula CClN and a molar mass of 184.5 g/mol?

42. Find the molecular formula of ethylene glycol, which is used as antifreeze. The molar mass is 62.0 g/mol, and the empirical formula is CH_3O.

10.3 LessonCheck

43. **Review** How do you calculate the percent by mass of an element in a compound?

44. **Identify** What information can you use to calculate the empirical formula of a compound?

45. **Explain** How is the molecular formula of a compound related to its empirical formula?

46. **Calculate** Determine the percent composition of the compound that forms when 222.6 g N combines completely with 77.4 g O.

47. **Calculate** Find the percent composition of calcium acetate, $Ca(C_2H_3O_2)_2$.

48. **Calculate** Using the results of Problem 47, calculate the grams of hydrogen in 124 g of $Ca(C_2H_3O_2)_2$.

BIGIDEA
THE MOLE AND QUANTIFYING MATTER

49. The compound methyl butanoate smells like apples. Its percent composition is 58.8% C, 9.8% H, and 31.4% O, and its molar mass is 102 g/mol. What is its empirical formula? What is its molecular formula?

Lesson Check Answers

43. Divide the mass of an element in the compound by the mass of the compound, then multiply by 100%.

44. The percent composition of a compound can be used to calculate the empirical formula of a compound.

45. The molecular formula of a compound is a simple whole-number multiple of the empirical formula.

46. 74.2% N, 25.8% O

47. 25.4% Ca, 30.4% C, 3.8% H, 40.5% O

48. 4.7 g

49. **BIG**IDEA $C_5H_{10}O_2$ is both its empirical and molecular formula.

Explain

Molecular Formulas

Sample Practice Problem

A compound is composed of carbon and hydrogen and has a molar mass of 86.0 grams per mole. Its empirical formula is C_3H_7. What is the molecular formula? (C_6H_{14})

Evaluate

Informal Assessment

Have students list verbally or in writing the steps they would take to calculate the molecular formula in each of the following situations:

1. The empirical formula and molar mass are known.
2. The percent composition and molar mass are known.

Then have students complete the 10.3 Lesson Check.

Reteach

Point out to students that when they know the percent composition and molar mass of a compound, they must first use the percent composition to calculate the empirical formula. They can then calculate the empirical formula mass and compare it to the molar mass of the molecular compound to determine the molecular formula. Help students to construct a flowchart or a concept map depicting the various scenarios.

Answers

INTERPRET DATA

a. 78 g
b. methanol, ethanoic acid, and glucose
c. The molar mass of glucose is six times greater than the molar mass of methanol.

FIGURE 10.12 Multiply the molar mass of methanal by 2.

41. $C_3Cl_3N_3$

42. molar mass/efm = 62/31 = 2
molecular formula = $2(CH_3O) = C_2H_6O_2$

CHEMISTRY & YOU Lead students in a discussion of Ion Mobility Spectrometry by having them describe experiences they have had going through airport security systems. If any students have gone through a puffer port, encourage them to explain what they saw and felt. Ask if they were concerned about the safety of going through the field or if they thought it was a fun experience. Point out that because of previous airline security alerts, people going through airport security often have to remove their shoes. With the puffer portal, this is unnecessary.

Pose the following question to students: *How do puffer portals differ from metal detectors and x-ray machines in their ability to detect potential weapons?* You may need to assist students in the following ways:

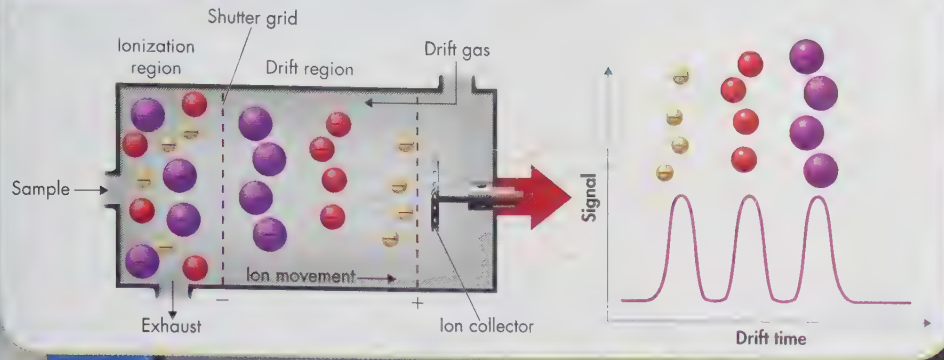
- Metal detectors detect many non-weapon metal objects, such as belt buckles, jewelry, keys, and medical hardware.
- Neither metal detectors nor x-ray machines can detect chemicals of any type on either clothing or other personal belongings.
- Metal detectors and x-ray machines rely heavily on human operators, who must sometimes re-scan passengers or luggage and who are prone to fatigue.
- Puffer portals require only seconds to scan and analyze any chemicals detected.

CHEMISTRY & YOU: TECHNOLOGY

Ion Mobility Spectrometry

In 2001, a terrorist boarded an airline flight with explosives inside his shoes. Since that time, Americans have had to remove their shoes during airport security checks. However, newer airport security devices, known as "puffer portals," allow airport security to scan for minute traces of explosives on a person's body and clothing, without the person having to remove any clothing or shoes.

The puffer portal looks like a standard airport metal detector. There are vents and nozzles on the walls and ceiling of the portal. When a passenger steps inside, the doors close, and the instrument sends sharp bursts of air to dislodge particles from his or her body, hair, and clothing. The air sample is then passed through a chemical analysis system called an ion mobility spectrometer (IMS). The IMS identifies compounds based on the amount of time it takes for ions to pass through an electrified field in a tube filled with a nonreactive gas (drift gas). This "drift time" is then compared to a database of drift times of different compounds. In this way, molecules of known explosive or narcotic materials can be detected and identified. If even a picogram of an explosive is detected, an alarm sounds.



PUFFING OUT EXPLOSIVES Bursts of air dislodge particles from a person's hair, body, and clothes. These particles are then directed to an ion mobility spectrometer (IMS).

21st Century Learning To be successful in the 21st century, students need skills and learning experiences that extend beyond subject matter mastery. The following project helps students build these 21st Century Skills: *Civic Literacy, Critical Thinking and Problem Solving, Communication and Collaboration, Social and Cross-Cultural Skills, Productivity and Accountability, and Leadership and Responsibility.*

SECURING THE SKIES Post the following challenge to your students. *Officials at an airport near you have just announced that they are increasing their security procedures. They will continue using metal detectors and luggage checks, but they will also install a puffer portal. Some people have complained that this is an invasion of privacy and unnecessary. Do you agree?* Form debate teams of two students each, and engage in a debate regarding the pros and cons of puffer portals. All teams should research both sides of the economic, security, and privacy issues thoroughly, and come prepared to argue either side. Have teams draw straws to determine which position they will argue on debate day.

A Closer Look

IDENTIFYING IONS When the particles enter the IMS, they are ionized, or converted into ions. The ionized particles then travel through a tube containing an electric field, which causes the ions to separate according to their masses, sizes, and shapes. For example, smaller ions move faster and reach the end of the tube before larger ions.

Take It Further

1. Calculate Two common explosive compounds are trinitrotoluene (TNT) and cyclotrimethylenetrinitramine (RDX). The chemical formula of TNT is $C_7H_5N_3O_6$. The chemical formula of RDX is $C_3H_6N_6O_6$. Calculate the molar masses of these two compounds.

2. Analyze Data If TNT and RDX molecules are separated in an IMS solely based on mass, which compound would reach the ion collector first?

3. Predict What do you think would be some other uses for ion mobility spectrometers?

Differentiated Instruction

L1 STRUGGLING STUDENTS Remind students that an ion is a charged atom. The atom has either gained or lost one or more electrons. As an example, have students draw a diagram of a nitrogen atom, and explain how it can change to an ion.

LPR LESS PROFICIENT READERS Have students work with a partner to identify at least five words in the feature that present them with difficulties. For each word, students should write a definition in their own words and use the word in a sentence.

L3 ADVANCED STUDENTS Have students consider other potential uses for the puffer portals. Examples include other security applications as well as detection of hazards at laboratories. Have students prepare a report describing the uses and possible alternatives to the design used for airport security.

Explain

USE VISUALS Have students study the picture of the ion mobility spectrometer. **Ask** Why is it necessary to ionize the particles before they move into the drift region? *(Ions have an electric charge and will respond to the electric field. Uncharged atoms will not.)* **Ask** What can scientists learn about the different masses of the ions? *(The masses indicate the type of element they are.)*

SUMMARIZE Have students write a summary statement explaining what the graph of signal vs. drift time shows. *(The graph shows that particles with different masses arrive at the detector at different times.)*

Extend

Connect to ECONOMICS

Each puffer portal costs well over $100,000. Have students ponder the question, *Is the price really worth the benefit?* Explain to students the concept of cost analysis, in which economists compare the cost of doing something to the potential costs that not doing it might incur. Have students work with a partner to analyze and estimate the costs of installing a puffer portal in an airport (cost of the machine, technician costs, upkeep costs) with the cost of not installing one (possibility of a terrorist threat and the expenses that would involve). *(Although students may have to estimate many of the costs, they should conclude that the cost of not installing the machine at an airport far exceeds the cost of installing it.)*

Answers

1. The molar mass of TNT is 227 g. The molar mass of RDX is 222 g.
2. The RDX molecules would reach the ion collector first.
3. Answers will vary but students might state that they could be used at courthouses or bus or train stations.

STUDY GUIDE

Evaluate

Review and Assessment Materials

WALK-THRU TUTORIALS Each of the Math Tune-Up problems on the following page has an animated step-by-step tutorial that explains the problem-solving strategy in detail.

PROBLEM SETS Have students practice solving more chemical quantity problems by using the Chapter 10 Online Problem Set.

MATH SKILLS Review Have struggling students practice solving algebraic equations by using the MathXL learning module.

VIRTUAL LABS Have students complete a virtual lab as an in-class or take-home assignment to help reinforce the mathematical relationships involved in calculating molar quantities.

Study Tip

ORGANIZE NEW INFORMATION Different people learn in different ways. Tell students that if they learn best visually, they should draw concept maps, outlines, and diagrams to help them organize the chapter content. If students learn best by listening, they can take turns reading the chapter aloud with a partner.

10 Study Guide

BIG IDEA

THE MOLE AND QUANTIFYING MATTER

The mole is an important measurement in chemistry. The mole allows you to convert among the amount of representative particles in a substance, the mass of a substance, and the volume of a gas at STP. The molecular formula of a compound can be determined by first finding the percent composition of the compound and determining the empirical formula. Using the empirical formula mass and the molar mass of the compound, the molecular formula can be determined.

10.1 The Mole: A Measurement of Matter

- Knowing how the count, mass, and volume of an item relate to a common unit allows you to convert among these units.
- The mole allows chemists to count the number of representative particles in a substance.
- The atomic mass of an element expressed in grams is the mass of a mole of the element.
- To calculate the molar mass of a compound, find the number of grams of each element in one mole of the compound. Then add the masses of the elements in the compound.

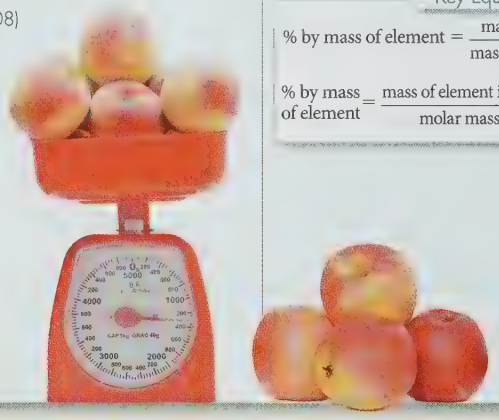
- mole (308)
- Avogadro's number (308)
- representative particle (308)
- molar mass (313)

10.2 Mole–Mass and Mole–Volume Relationships

- Use the molar mass of an element or compound to convert between the mass of a substance and the moles of the substance.
- The molar volume is used to convert between the number of moles of gas and the volume of the gas at STP.

- Avogadro's hypothesis (320)
- standard temperature and pressure (STP) (320)
- molar volume (320)

10.3 Percent Composition and Chemical Formulas



- The percent by mass of an element in a compound is the number of grams of the element divided by the mass in grams of the compound, multiplied by 100%.
- The percent composition of a compound can be used to calculate the empirical formula of that compound.
- The molecular formula of a compound is either the same as its experimentally determined empirical formula, or it is a simple whole-number multiple of its empirical formula.

- percent composition (325)
- empirical formula (330)

Key Equations

$$\%\text{ by mass of element} = \frac{\text{mass of element}}{\text{mass of compound}} \times 100\%$$

$$\%\text{ by mass of element} = \frac{\text{mass of element in 1 mol compound}}{\text{molar mass of compound}} \times 100\%$$

UbD

Understanding by Design

Performance Tasks

WHAT'S IN A MOLE? Write the following information on the board: Nitrous oxide (N_2O) has a density of 1.977 g/L. Without consulting a periodic table, calculate the following for 7.43 mol of N_2O: molar mass, total mass, number of representative particles, and number of atoms. *(molar mass = 44.3 g/mol; total mass = 3.29 × 10^2 g; 4.47 × 10^{24} representative particles; 1.34 × 10^{25} atoms)*

WHAT PART OF NO... Have students determine the percent composition, empirical formula, and molecular formula for a sample of colorless gas that contains 10.9 g N and 25.1 g O. The molar mass for this compound is 92.0 g/mol. *(percent composition: 30.4% N, 69.6% O; empirical formula: NO_2; molecular formula: N_2O_4)*

Math Tune-Up: Mole Problems

Problem	❶ Analyze	❷ Calculate	❸ Evaluate
How many moles of lithium (Li) is 4.81×10^{24} atoms of lithium?	Knowns: number of atoms = 4.81×10^{24} atoms Li 1 mol Li = 6.02×10^{23} atoms Li Unknown: moles = ? mol Li The desired conversion is atoms ⟶ moles.	Use the correct conversion factor to convert from atoms to moles. $4.81 \times 10^{24}\ \text{atoms Li} \times \frac{1\ \text{mol Li}}{6.02 \times 10^{23}\ \text{atoms Li}} = 7.99\ \text{mol Li}$ Hint: Review Sample Problems 10.2 and 10.3 if you have trouble converting between number of representative particles and moles.	The given number of atoms is about 8 times Avogadro's number, so the answer should be around 8 mol of atoms.
Calculate the mass in grams of 0.160 mol H_2O_2.	Known: number of moles = 0.160 mol H_2O_2 Unknown: mass = ? g H_2O_2 The desired conversion is moles ⟶ mass.	Determine the molar mass of H_2O_2 and use the correct conversion factor to convert from moles to grams. 1 mol H_2O_2 = (2 mol)(1.0 g/mol) + (2 mol)(16.0 g/mol) = 34.0 g H_2O_2 $0.160\ \text{mol } H_2O_2 \times \frac{34.0\ \text{g } H_2O_2}{1\ \text{mol } H_2O_2} = 5.44\ \text{g } H_2O_2$	The number of moles of H_2O_2 is about 0.2, and the molar mass is about 30 g/mol. The answer should be around 6 g.
What is the volume of 1.25 mol He at STP?	Knowns: number of moles = 1.25 mol He 1 mol He at STP = 22.4 L He Unknown: volume = ? L He The desired conversion is moles ⟶ volume at STP.	Use the correct conversion factor to convert from moles to volume at STP. $1.25\ \text{mol He} \times \frac{22.4\ \text{L He}}{1\ \text{mol He}} = 28.0\ \text{L}$ Remember: A mole of any gas at STP occupies a volume of 22.4 L.	One mole of gas at STP has a volume of 22.4 L, so 1.25 mol should have a volume larger than 22.4 L.
What is the percent composition of the compound formed when 29.0 g Ag combines completely with 4.30 g S?	Knowns: mass of Ag = 29.0 g Ag mass of S = 4.30 g S mass of compound = 29.0 g + 4.30 g = 33.3 g Unknowns: percent by mass of Ag = ?% Ag percent by mass of S = ?% S Use the equation: % by mass of element = $\frac{\text{mass of element}}{\text{mass of compound}} \times 100\%$	Calculate the percent by mass of Ag and S in the compound. $\%\text{Ag} = \frac{29.0\ g}{33.3\ g} \times 100\%$ %Ag = 87.1% Ag $\%\text{S} = \frac{4.30\ g}{33.3\ g} \times 100\%$ %S = 12.9% S Hint: Review Sample Problems 10.9 and 10.10 if you have trouble calculating the percent composition of a compound.	The percents of the elements add up to 100%.

Focus on ELL

5 ASSESS UNDERSTANDING Use or create a formative assessment for each lesson to determine the students' level of understanding.

BEGINNING

LOW Create an assessment in which students match symbols, pictures, or diagrams to vocabulary words, conversion factors, or concepts.

HIGH Allow students to use their native language glossary as a reference during the assessment.

INTERMEDIATE: LOW/HIGH Assign the Standardized Test Prep. Tell students to cross out wrong answers. Model how to complete the answer sheet.

ADVANCED: LOW/HIGH Assign students a five question assessment involving mass and mole conversion problems and volume and mole conversion problems. Have students indicate the correct answers and provide an analysis for each wrong answer choice.

Math Review

50. Number, mass, or volume; examples will vary.

51. **a.** molecule
b. formula unit
c. molecule
d. atom

52. **a.** 3
b. 2
c. 9
d. 10

53. A mole of any substance contains Avogadro's number of representative particles.

54. **a.** 4.00 mol NaCl
b. 15.0 mol Hg
c. 7.72 molecules NO_2

55. All contain 6.02×10^{23} molecules

56. 1.00 mol C_2H_6

57. **a.** 1.81×10^{24} atoms Sn
b. 2.41×10^{23} formula units KCl
c. 4.52×10^{24} molecules SO_2
d. 2.89×10^{21} formula units NaI

58. 71.0 g/mol Cl_2

59. Answers will vary but should include
1. Determine the moles of each atom from the formula.
2. Look up the atomic mass of each element.
3. Multiply the number of moles of each atom by its molar mass.
4. Sum these products.

60. **a.** 98.0 g/mol
b. 76.0 g/mol
c. 100.1 g/mol
d. 132.1 g/mol
e. 89.0 g/mol
f. 159.8 g/mol

61. **a.** 60.1 g/mol
b. 28.0 g/mol
c. 106.8 g/mol
d. 63.5 g/mol

LESSON 10.2

62. **a.** 108 g C_5H_{12}
b. 547 g F_2
c. 71.8 g $Ca(CN)_2$
d. 238 g H_2O_2
e. 224 g NaOH
f. 1.88 g Ni

63. **a.** 85.5 g $C_{12}H_{22}O_{11}$
b. 14.6 g NaCl
c. 39.5 g $KMnO_4$

64. **a.** 0.292 mol $C_{12}H_{22}O_{11}$
b. 1.71 mol NaCl
c. 0.633 mol $KMnO_4$

10 Assessment

* Solutions appear in Appendix E

Lesson by Lesson

10.1 The Mole: A Measurement of Matter

50. List three common ways that matter is measured. Give examples of each.

***51.** Name the representative particle (atom, molecule, or formula unit) of each substance.
a. oxygen gas
b. sodium sulfide
c. sulfur dioxide
d. potassium

***52.** How many hydrogen atoms are in a representative particle of each substance?
a. $Al(OH)_3$
b. $H_2C_2O_4$
c. $(NH_4)_2HPO_4$
d. $C_4H_{10}O$

53. Describe the relationship between Avogadro's number and one mole of any substance.

***54.** Find the number of moles in each substance.
a. 2.41×10^{24} formula units of NaCl
b. 9.03×10^{24} atoms of Hg
c. 4.65×10^{24} molecules of NO_2

55. Which contains more molecules: 1.00 mol H_2O_2, 1.00 mol C_2H_6, or 1.00 mol CO?

56. Which contains more atoms: 1.00 mol H_2O_2, 1.00 mol C_2H_6, or 1.00 mol CO?

***57.** Find the number of representative particles in each substance.
a. 3.00 mol Sn
b. 0.400 mol KCl
c. 7.50 mol SO_2
d. 4.80×10^{-3} mol NaI

58. What is the molar mass of chlorine?

59. List the steps you would take to calculate the molar mass of any compound.

***60.** Calculate the molar mass of each substance.
a. H_3PO_4
b. N_2O_3
c. $CaCO_3$
d. $(NH_4)_2SO_4$
e. $C_4H_9O_2$
f. Br_2

61. Calculate the mass of 1.00 mol of each of these substances.
a. silicon dioxide (SiO_2)
b. diatomic nitrogen (N_2)
c. iron(III) hydroxide ($Fe(OH)_3$)
d. copper (Cu)

10.2 Mole–Mass and Mole–Volume Relationships

62. Find the mass of each substance.
a. 1.50 mol C_5H_{12}
b. 14.4 mol F_2
c. 0.780 mol $Ca(CN)_2$
d. 7.00 mol H_2O_2
e. 5.60 mol NaOH
f. 3.21×10^{-2} mol Ni

***63.** Calculate the mass in grams of 0.250 mol of each of the following compounds:
a. sucrose ($C_{12}H_{22}O_{11}$)
b. sodium chloride (NaCl)
c. potassium permanganate ($KMnO_4$)

***64.** Calculate the number of moles in 1.00×10^2 g of each of the compounds in Problem 63.

65. How many moles is each of the following?
a. 15.5 g SiO_2
b. 0.0688 g AgCl
c. 79.3 g Cl_2
d. 5.96 g KOH
e. 937 g $Ca(C_2H_3O_2)_2$
f. 0.800 g Ca

66. What is the volume of one mole of any gas at STP?

***67.** Calculate the volume of each of the following gases at STP.
a. 7.64 mol Ar
b. 1.34 mol SO_2
c. 0.442 mol C_2H_6
d. 2.45×10^{-3} mol H_2S

***68.** A gas has a density of 0.902 g/L at STP. What is the molar mass of this gas?

69. What is the density of each of the following gases at STP?
a. C_3H_8
b. O_2
c. Ne
d. NO_2

70. Find each of the following quantities:
a. the volume, in liters, of 835 g SO_3 at STP
b. the mass, in grams, of a molecule of aspirin ($C_9H_8O_4$)
c. the number of atoms in 5.78 mol NH_4NO_3

10.3 Percent Composition and Chemical Formulas

71. What is the percent composition of the compound formed when 2.70 g of aluminum combine with oxygen to form 5.10 g of aluminum oxide?

65. **a.** 0.258 mol SiO_2
b. 4.80×10^{-4} mol AgCl
c. 1.12 mol Cl_2
d. 0.106 mol KOH
e. 5.93 mol $Ca(C_2H_3O_2)_2$
f. 2.00×10^{-2} mol Ca

66. 22.4 L

67. **a.** 171 L Ar
b. 30.0 L SO_2
c. 9.90 L C_2H_6
d. 5.49×10^{-2} L H_2S

68. 20.2 g/mol

69. **a.** 1.96 g/L
b. 1.43 g/L
c. 0.902 g/L
d. 2.05 g/L

70. **a.** 234 L SO_3
b. 2.99×10^{-22} g $C_9H_8O_4$
c. 3.13×10^{25} atoms

LESSON 10.3

71. 53% Aluminum and 47% Oxygen

*72. Calculate the percent composition when 13.3 g Fe combine completely with 5.7 g O.

*73. Calculate the percent composition of each compound.

a. H_2S
b. $(NH_4)_2C_2O_4$
c. $Mg(OH)_2$
d. Na_3PO_4

*74. Using your answers from Problem 73, calculate the number of grams of these elements.

a. sulfur in 3.54 g H_2S
b. nitrogen in 25.0 g $(NH_4)_2C_2O_4$
c. magnesium in 97.4 g $Mg(OH)_2$
d. phosphorus in 804 g Na_3PO_4

75. Which of the following compounds has the highest percent of iron by mass?

a. $FeCl_2$
b. $Fe(C_2H_3O_2)_3$
c. $Fe(OH)_2$
d. FeO

*76. What is an empirical formula? Which of the following molecular formulas are also empirical formulas?

a. ribose ($C_5H_{10}O_5$)
b. ethyl butyrate ($C_6H_{12}O_2$)
c. chlorophyll ($C_{55}H_{72}MgN_4O_5$)
d. DEET ($C_{12}H_{17}ON$)

77. Which of the following can be classified as an empirical formula?

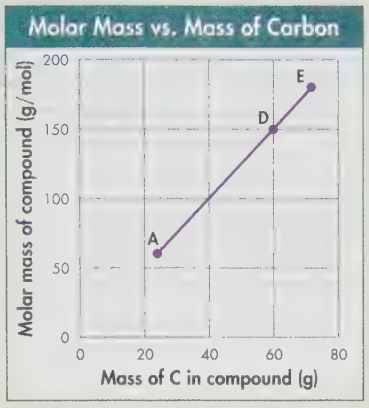
a. S_2Cl_2 b. $C_6H_{10}O_4$ c. Na_2SO_3

78. Which pair of molecules has the same empirical formula?

a. $C_2H_4O_2$, $C_6H_{12}O_6$
b. $NaCrO_4$, $Na_2Cr_2O_7$

*79. What is the molecular formula for each compound? Each compound's empirical formula and molar mass are given.

a. CH_2O, 90 g/mol b. HgCl, 472.2 g/mol



Understand Concepts

*80. Table sugar, or sucrose, has the chemical formula $C_{12}H_{22}O_{11}$.

a. How many atoms are in 1.00 mol of sucrose?
b. How many atoms of C are in 2.00 mol of sucrose?
c. How many atoms of H are in 2.00 mol of sucrose?
d. How many atoms of O are in 3.65 mol of sucrose?

81. How can you determine the molar mass of a gaseous compound if you do not know its molecular formula?

*82. A series of compounds has the empirical formula CH_2O. The graph shows the relationship between the molar mass of the compounds and the mass of carbon in each compound.

a. What are the molecular formulas for the compounds represented by data points A, D, and E?
b. Find the slope of the line. Is this value consistent with the empirical formula? Explain.
c. Two other valid data points fall on the line between points A and D. What are the x, y values for these data points?

83. Explain what is wrong with each statement.

a. One mole of any substance contains the same number of atoms.
b. A mole and a molecule of a substance are identical in amount.
c. One molar mass of CO_2 contains Avogadro's number of atoms.

84. Which of the following contains the largest number of atoms?

a. 82.0 g Kr
b. 0.842 mol C_2H_4
c. 36.0 g N_2

*85. Calculate the grams of oxygen in 90.0 g of Cl_2O.

86. What is the total mass of a mixture of 3.50×10^{22} formula units Na_2SO_4, 0.500 mol H_2O, and 7.23 g AgCl?

72. 70% Fe and 30% O
73. **a.** 5.9% H; 94.1%S
b. 22.6% N; 6.5% H; 19.4% C; 51.6% O
c. 41.7% Mg; 54.9% O; 3.4% H
d. 42.1% Na; 18.9% P; 39.0% O
74. **a.** 3.33 g S
b. 5.65 g N
c. 40.6 g Mg
d. 152 g P
75. **d.** 77.7% Fe in FeO
76. An empirical formula has the lowest whole-number ratio of elements.;
a. molecular; **b.** molecular; **c.** molecular and empirical; **d.** molecular and empirical
77. **a.** molecular **b.** molecular **c.** empirical
78. a
79. **a.** $C_3H_6O_3$
b. Hg_2Cl_2

UNDERSTAND CONCEPTS

80. **a.** 2.71×10^{25} atoms
b. 1.44×10^{25} C atoms
c. 2.65×10^{25} H atoms
d. 2.42×10^{25} O atoms
81. You can measure the mass of 22.4 L of the compound at STP; this is the molar volume of the gas. The mass of the molar volume is the molar mass.
82. **a.** A, $C_2H_4O_2$; D, $C_5H_{10}O_5$; E, $C_6H_{12}O_6$
b. slope = 2.5/1, which is the ratio of the molar mass of the empirical formula to the mass of carbon in the empirical formula: 30/12 = 2.5/1.
c. (36, 90) and (48, 120)
83. **a.** A molecule is composed of two or more atoms.
b. There are 6.02×10^{23} molecules in 1 mol of a molecular substance.
c. A mole of CO_2 has 3 times Avogadro's number of atoms.
84. **b.** 0.842 mol C_2H_4
85. 16.6 g O
86. 24.5 g

ASSESSMENT

Evaluate

Answers

87. 2.73×10^{20} F atoms

88. **a.** CO
b. $C_2O_2NH_5$
c. Cl_2OC

89. **a.** H_2O_2
b. $C_6H_6O_4$
c. K_2CO_3

90. **a.** 27.0 amu
b. aluminum

91. 3×10^{13} km

92. **a.** $CuBr_2$
b. CH_3

93. $C_3H_6O_3$

94. 0.98 g He

95. 3.34×10^{25} molecules H_2O

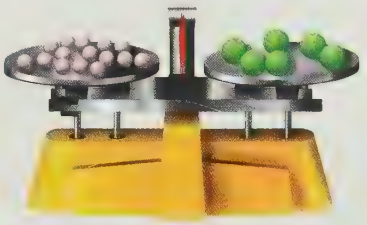
THINK CRITICALLY

96. C_2H_6O.

97. A molecular formula is a whole- number multiple of its empirical formula.

98. Sulfur atoms have a greater atomic mass. The most abundant sulfur atom has 16 protons, 16 electrons, and 16 neutrons; carbon is composed of 6 protons, 6 electrons, and 6 neutrons. Therefore, 6.02×10^{23} sulfur atoms will have a greater mass than the same number of carbon atoms.

99. Gas molecules are separated by so much empty space their own volumes are insignificant in determining how much space a certain quantity of gas molecules occupies.



100. **a.** $C_9H_{11}O_2N$
b. $C_9H_{11}O_2N$

***87.** The molecular formula of an antibacterial drug is $C_{17}H_{18}FN_3O_3$. How many fluorine atoms are in a 150-mg tablet of this drug?

88. Determine the empirical formulas of compounds with the following percent compositions:
a. 42.9% C and 57.1% O
b. 32.00% C, 42.66% O, 18.67% N, and 6.67% H
c. 71.72% Cl, 16.16% O, and 12.12% C

***89.** Determine the molecular formula for each compound.
a. 94.1% O and 5.9% H; molar mass = 34 g/mol
b. 50.7% C, 4.2% H, and 45.1% O; molar mass = 142 g/mol
c. 56.6% K, 8.7% C, and 34.7% O; molar mass = 138.2 g/mol

***90.** A fictitious "atomic balance" is shown below. Fifteen atoms of boron on the left side of the balance are balanced by six atoms of an unknown element E on the right side.

a. What is the atomic mass of element E?
b. What is the identity of element E?

***91.** A typical virus is 5×10^{-6} cm in diameter. If Avogadro's number of these virus particles were laid in a row, how many kilometers long would the line be?

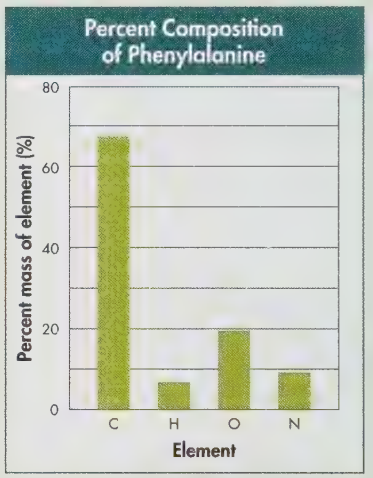
92. Calculate the empirical formula for each compound.
a. compound consisting of 0.40 mol Cu and 0.80 mol Br
b. compound with 4 atoms of carbon for every 12 atoms of hydrogen

93. Muscle fatigue can result from the buildup of lactic acid. The percent composition of lactic acid is 40.0% C, 6.67% H, and 53.3% O. What is the molecular formula of lactic acid if its molar mass is 90.0 g/mol?

***94.** What mass of helium is needed to inflate a balloon to a volume of 5.50 L at STP?

95. How many water molecules are in a 1.00-L bottle of water? The density of water is 1.00 g/mL.

Think Critically



***96. Infer** What is the empirical formula of a compound that has three times as many hydrogen atoms as carbon atoms but only half as many oxygen atoms as carbon atoms?

97. Apply Concepts How are the empirical and molecular formulas of a compound related?

98. Compare Why does one mole of carbon have a smaller mass than one mole of sulfur? How are the atomic structures of these elements different?

99. Analyze Data One mole of any gas at STP equals 22.4 L of that gas. It is also true that different elements have different atomic volumes, or diameters. How can you reconcile these two statements?

***100. Interpret Graphs** The graph shows the percent composition of phenylalanine.

a. What is the empirical formula for phenylalanine?
b. If the molar mass of phenylalanine is 165.2 g/mol, what is its molecular formula?

Enrichment

*101. **Infer** Nitroglycerine contains 60% as many carbon atoms as hydrogen atoms, three times as many oxygen atoms as nitrogen atoms, and the same number of carbon and nitrogen atoms. The number of moles of nitroglycerine in 1.00 g is 0.00441. What is the molecular formula of nitroglycerine?

102. **Calculate** The density of nickel is 8.91 g/cm^3. How large a cube, in cm^3, would contain 2.00×10^{24} atoms of nickel?

*103. **Calculate** Dry air is about 20.95% oxygen by volume. Assuming STP, how many oxygen molecules are in a 75.0-g sample of air? The density of air is 1.19 g/L.

104. **Graph** The table below gives the molar mass and density of seven gases at STP.

Substance	Molar mass (g/mol)	Density (g/L)
Oxygen	32.0	1.43
Carbon dioxide	44.0	1.96
Ethane	30.0	1.34
Hydrogen	2.0	0.089
Sulfur dioxide	64.1	2.86
Ammonia	17.0	0.759
Fluorine	38.0	1.70

a. Plot these data, with density on the *x*-axis.
b. What is the slope of the straight-line plot?
c. What is the molar mass of a gas at STP that has a density of 1.10 g/L?
d. A mole of a gas at STP has a mass of 56.0 g. Use the graph to determine its density.

*105. **Calculate** Avogadro's number has been determined by about 20 different methods. In one approach, the spacing between ions in an ionic substance is determined by using a technique called X-ray diffraction. X-ray diffraction studies of sodium chloride have shown that the distance between adjacent Na^+ and Cl^- ions is 2.819×10^{-8} cm. The density of solid NaCl is 2.165 g/cm^3. By calculating the molar mass to four significant figures, you can determine Avogadro's number. What value do you obtain?

106. **Use Models** In Chapter 3, you learned that the densities of solids and liquids are measured in g/cm^3, but the densities of gases are measured in g/L. Draw atomic diagrams of a solid and of a gas that show why the two different units are practical.

Write About Science

107. Connect to the **BIG**IDEA Research the history of Avogadro's number. What elements other than carbon have been used to define a mole? Write a report that summarizes your findings.

CHEMYSTERY

A Formula for Cheating

Typically, steroids can be detected in an athlete's urine. A urine sample is collected and is first injected into an instrument that separates the chemical compounds in the urine.

The separated compounds are then analyzed using a mass spectrometer. The mass spectrometer provides information such as the molar mass of the compounds present in the urine sample and the molecular structure of these compounds. These structures can be compared against a database of known compounds to identify the presence of steroids in the sample.

*108. **Calculate** Analysis of an athlete's urine found the presence of a compound with a molar mass of 312 g/mol. How many moles of this compound are contained in 30.0 mg? How many molecules of the compound is this?

109. Connect to the **BIG**IDEA The compound found in the athlete's urine, the steroid THG, has a percent composition of 80.8% carbon, 8.97% hydrogen, and 10.3% oxygen. What is the empirical formula of THG? If the molar mass of THG is 312 g/mol, what is the molecular formula?

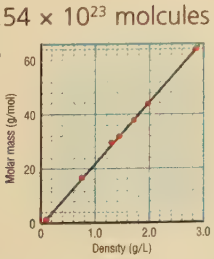
Explain

CHEMYSTERY

START A CONVERSATION Point out that the mass spectrometer determines the molar masses of all the chemical compounds in the urine, including those that are expected to be present in normal urine. **Ask** How might the laboratory chemist prove that the substance detected by the instrument is not a normal component of urine? *(Analyze a sample of urine that is known to be drug-free, and compare the results of the two samples.)* Note that it is important for the mass spectrometer's data processor to use both structure and molar mass data to identify the drugs, as there may be more than one compound with the same molar mass.

CHEMYSTERY ANSWERS

108. 5.79×10^{19} molecules



109. **BIG**IDEA Both the empirical and molecular formulas of THG are $C_{21}H_{28}O_2$.

ASSESSMENT

Answers

ENRICHMENT

101. $C_3H_5O_9N_3$
102. 21.9 cm^3
103. 3.54×10^{23} molcules O_2
104. a.

b. 22.4 L/mol
c. 24.6 g/mol
d. 2.5 g/L
105. 6.025×10^{23} formula units/mol
106. Diagrams should show the particles in a solid much more closely packed together those of a gas. This closely packed arrangement of particles means that solids are much denser than gases. Thus, it makes sense to use a larger unit, g/cm^3, to measure the density of solids.

WRITE ABOUT SCIENCE

107. Students should mention the work of Johann Josef Loschmidt and Jean Perrin in their reports. They should also state why the constant is named after Amedeo Avogadro. Prior to carbon, hydrogen and oxygen were used to define the mole.

CUMULATIVE REVIEW

110. chemical change: wax burning
physical change: wax melting
physical change: wax vaporizing

111. **a.** physical change
b. chemical change
c. chemical change
d. physical change
e. chemical change
f. physical change

112. b, d

113. No; the student has ignored the units. The density of sugar is 1.59 g/mL; the density of carbon dioxide is much less, 1.83 g/L.

114. The block will float. Its density, 0.848 g/mL, is less than the density of water.

115. **a.** 4.72×10^3 mg
b. 97 km/h
c. 4.4×10^{-2} dm

116. **a.** 40 protons, 40 electrons, 50 neutrons
b. 46 protons, 46 electrons, 62 neutrons
c. 35 protons, 35 electrons, 46 neutrons
d. 51 protons, 51 electrons, 72 neutrons

117. **a.** $1s^2 2s^2 2p^5$
b. $1s^2 2s^1$
c. $1s^2 2s^2 2p^6 3s^2 3p^6 3d^{10} 4s^2 4p^6 5s^1$

118. Magnesium and barium are both in Group 2A and have 2 valence electrons.

119. Cr, Cd, Cu, and Co

120. For Group A elements, the group number equals the number of valence electrons.

121. A molecule is composed of two or more atoms.

122. **a.** pyramidal $H{:}\ddot{\underset{\ddot{H}}{P}}{:}H$ **c.** linear $:\ddot{S}::C::\ddot{S}:$ ($:\ddot{F}:$)
b. linear $:O::C:$ **d.** tetrahedral $:\ddot{F}{-}\underset{:\ddot{F}:}{\overset{:\ddot{F}:}{\underset{|}{\overset{|}{C}}}}{-}\ddot{F}:$

123. For single bond a single line connects the atoms (X—X). Atoms are connected by two lines in a double bond (X=X), and three lines in a triple bond (XX).

124. Answers will vary. **a.** carbon monoxide (CO)
b. ozone (O_3) **c.** nitrogen dioxide (NO_2)

125. Calculate the electronegativity difference between two atoms. If the difference is small (0.0—0.4) the bond is nonpolar covalent. If the difference 2.0, the bond is most likely ionic. For values between 0.4 and 2.0, the bond is polar covalent.

126. **d.** CaS_2 **f.** BaOH

127. **a.** iron(III) hydroxide
b. ammonium iodide
c. sodium carbonate
d. carbon tetrachloride

128. **a.** KNO_3 **b.** CuO **c.** Mg_3N_2 **d.** AgF

Cumulative Review

*110. Identify at least one chemical change and two physical changes that are occurring in the photo.

*111. Classify each of the following as a physical change or a chemical change.
a. An aspirin tablet is crushed to a powder.
b. A red rose turns brown.
c. Grape juice turns to wine.
d. Fingernail polish remover evaporates.
e. A bean seed sprouts.
f. A piece of copper is beaten into a thin sheet.

112. Which of these statements are true about every solution?
a. Solutions are in the liquid state.
b. Solutions are homogeneous.
c. Solutions are mixtures.
d. Solutions are composed of at least two compounds.

113. A student writes down the density of table sugar as 1.59 and the density of carbon dioxide as 1.83. Can these values be correct? Explain.

*114. A block of wood measuring 2.75 cm × 4.80 cm × 7.50 cm has a mass of 84.0 g. Will the block of wood sink or float in water?

*115. Convert each of the following:
a. 4.72 g to mg
b. 2.7×10^3 cm/s to km/h
c. 4.4 mm to dm

*116. How many protons, electrons, and neutrons are in each isotope?
a. zirconium-90 **c.** bromine-81
b. palladium-108 **d.** antimony-123

*117. Write the complete electron configuration for each atom.
a. fluorine **b.** lithium **c.** rubidium

118. Why do the elements magnesium and barium have similar chemical and physical properties?

*119. Which of the following are transition metals: Cr, Cd, Ca, Cu, Co, Cs, Ce?

120. How can the periodic table be used to infer the number of valence electrons in an atom?

121. How does a molecule differ from an atom?

122. Draw electron dot structures and predict the shapes of the following molecules:
a. PH_3 **b.** CO **c.** CS_2 **d.** CF_4

123. How are single, double, and triple bonds indicated in electron dot structures?

124. Give an example of each of the following:
a. coordinate covalent bonding
b. resonance structures
c. exceptions to the octet rule

125. Explain how you can use electronegativity values to classify a bond as nonpolar covalent, polar covalent, or ionic.

*126. Identify any incorrect formulas among the following:
a. H_2O_2 **d.** CaS_2
b. $NaIO_4$ **e.** $CaHPO_4$
c. SrO **f.** BaOH

*127. Name these compounds.
a. $Fe(OH)_3$ **c.** Na_2CO_3
b. NH_4I **d.** CCl_4

*128. Write formulas for these compounds.
a. potassium nitrate
b. copper(II) oxide
c. magnesium nitride
d. silver fluoride

Tips for Success

Wear a Watch Be aware of how many questions you have to answer and how much time you have to answer them. Look at your watch or a clock frequently to keep track of your progress.

1. Choose the term that best completes the second relationship.

   a. dozen : eggs
   mole : _____
   (A) atoms (C) size
   (B) 6.02×10^{23} (D) grams

   b. mole : Avogadro's number
   molar volume : _____
   (A) mole (C) STP
   (B) water (D) 22.4 L

Select the choice that best answers each question or completes each statement.

2. Calculate the molar mass of ammonium phosphate, $(NH_4)_3PO_4$.
   (A) 113.0 g/mol (C) 149.0 g/mol
   (B) 121.0 g/mol (D) 242.0 g/mol

3. Based on the structural formula below, what is the empirical formula for tartaric acid, a compound found in grape juice?

   (A) $C_2H_3O_3$ (C) CHO
   (B) $C_4H_6O_6$ (D) $C_1H_{1.5}O_{1.5}$

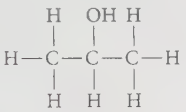
4. How many hydrogen atoms are in six molecules of ethylene glycol, $C_2H_6O_2$?
   (A) 6 (C) $6 \times (6.02 \times 10^{23})$
   (B) 36 (D) $36 \times (6.02 \times 10^{23})$

5. Which of these compounds has the largest percent by mass of nitrogen?
   (A) N_2O (D) N_2O_3
   (B) NO (E) N_2O_4
   (C) NO_2

6. Which of these statements is true of a balloon filled with 1.00 mol $N_2(g)$ at STP?
   I. The balloon has a volume of 22.4 L.
   II. The contents of the balloon have a mass of 14.0 g.
   III. The balloon contains 6.02×10^{23} molecules.
   (A) I only (C) I and III only
   (B) I and II only (D) I, II, and III

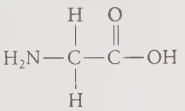
7. Allicin, $C_6H_{10}S_2O$, is the compound that gives garlic its odor. A sample of allicin contains 3.0×10^{21} atoms of carbon. How many hydrogen atoms does this sample contain?
   (A) 10 (C) 1.8×10^{21}
   (B) 1.0×10^{21} (D) 5.0×10^{21}

The lettered choices below refer to Questions 8–11. A lettered choice may be used once, more than once, or not at all.



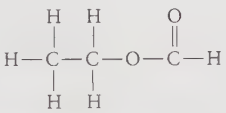
(A) CH (B) CH_2 (C) C_2H_5 (D) CH_3 (E) C_2H_3

Which of the formulas is the empirical formula for each of the following compounds?



8. C_8H_{12}
9. C_6H_6
10. C_2H_6
11. C_4H_{10}

For Questions 12–14, write the molecular formula for each compound whose structural formula is shown. Then calculate the compound's molar mass.



12.

Materials List

For the Student

Quick Lab, p 354
- aluminum foil, 20 cm by 20 cm
- large beaker or glass pan
- tarnished silver fork or spoon
- sodium hydrogen carbonate
- plastic tablespoon
- hot water

Small-Scale Lab, p 374
- reaction surface
- 0.05*M* $AgNO_3$, 0.2*M* $Pb(NO_3)_2$, 0.5*M* $CaCl_2$, 1.0*M* Na_2CO_3, 0.1*M* Na_3PO_4, 0.5*M* NaOH, 0.2*M* Na_2SO_4, 1.0*M* NaCl

For the Teacher

Teacher Demo, p 350
- 150-mL glass beaker
- table sugar
- fume hood
- concentrated sulfuric acid

Teacher Demo, p 352
- 100-mL graduated cylinder
- 0.1*M* copper(II) chloride solution
- 400-mL beaker
- metric ruler
- scissors
- aluminum foil

Teacher Demo, p 360
- magnesium ribbon
- 10-mL graduated cylinder
- 1*M* HCl
- sodium
- 2 beakers
- tongs
- water

Teacher Demo, p 362
- equimolar solutions of $BaCl_2$, Na_2SO_4, Na_3PO_4, $CaCl_2$, $Pb(NO_3)_2$, and KI

Teacher Demo, p 365
- superfine steel wool
- plastic sandwich bag
- balance
- ring stand
- utility clamp
- matches

Teacher Demo, p 366
- magnesium ribbon
- large crucible
- lab burner
- cobalt blue glass or exposed photographic film
- crucible tongs
- matches or igniter

Online Student Edition
Online Teacher's Edition
11.3 Virtual Chem Labs 22–24
Identification of Cations in Solutions

What's Online

CHEM TUTOR Students access guided, step-by-step tutorials for solving various chemical reaction problems.

PROBLEM SETS Students can practice key problem-solving skills in an online problem set.

MATH HELP Identify the students that struggle with math by assigning an online math skills diagnostic test. These students can then improve and practice math skills by using the MathXL tutorial system.

VIRTUAL LAB Students go on an animated virtual lab tour in which chemical reactions are studied in a simulated laboratory environment.

KINETIC ART Student watch animations of a selected figures from the chapter followed by questions to check for understanding.

CONCEPTS IN ACTION Students watch an overview of a key chapter concept using real-world contexts and concrete examples and analogies. Each activity includes an interactive animation followed by analysis questions.

IN ACADEMIC STANDARDS for SCIENCE

Standard 1: Properties and States of Matter

C.1.4 Describe physical and chemical changes at the molecular level.

Standard 4: Reactions and Stoichiometry

C.4.1 Predict products of simple reactions.

C.4.2 Balance chemical equations using the law of conservation of mass and use them to describe chemical reactions.

C.4.5 Recognize and classify types of reactions.

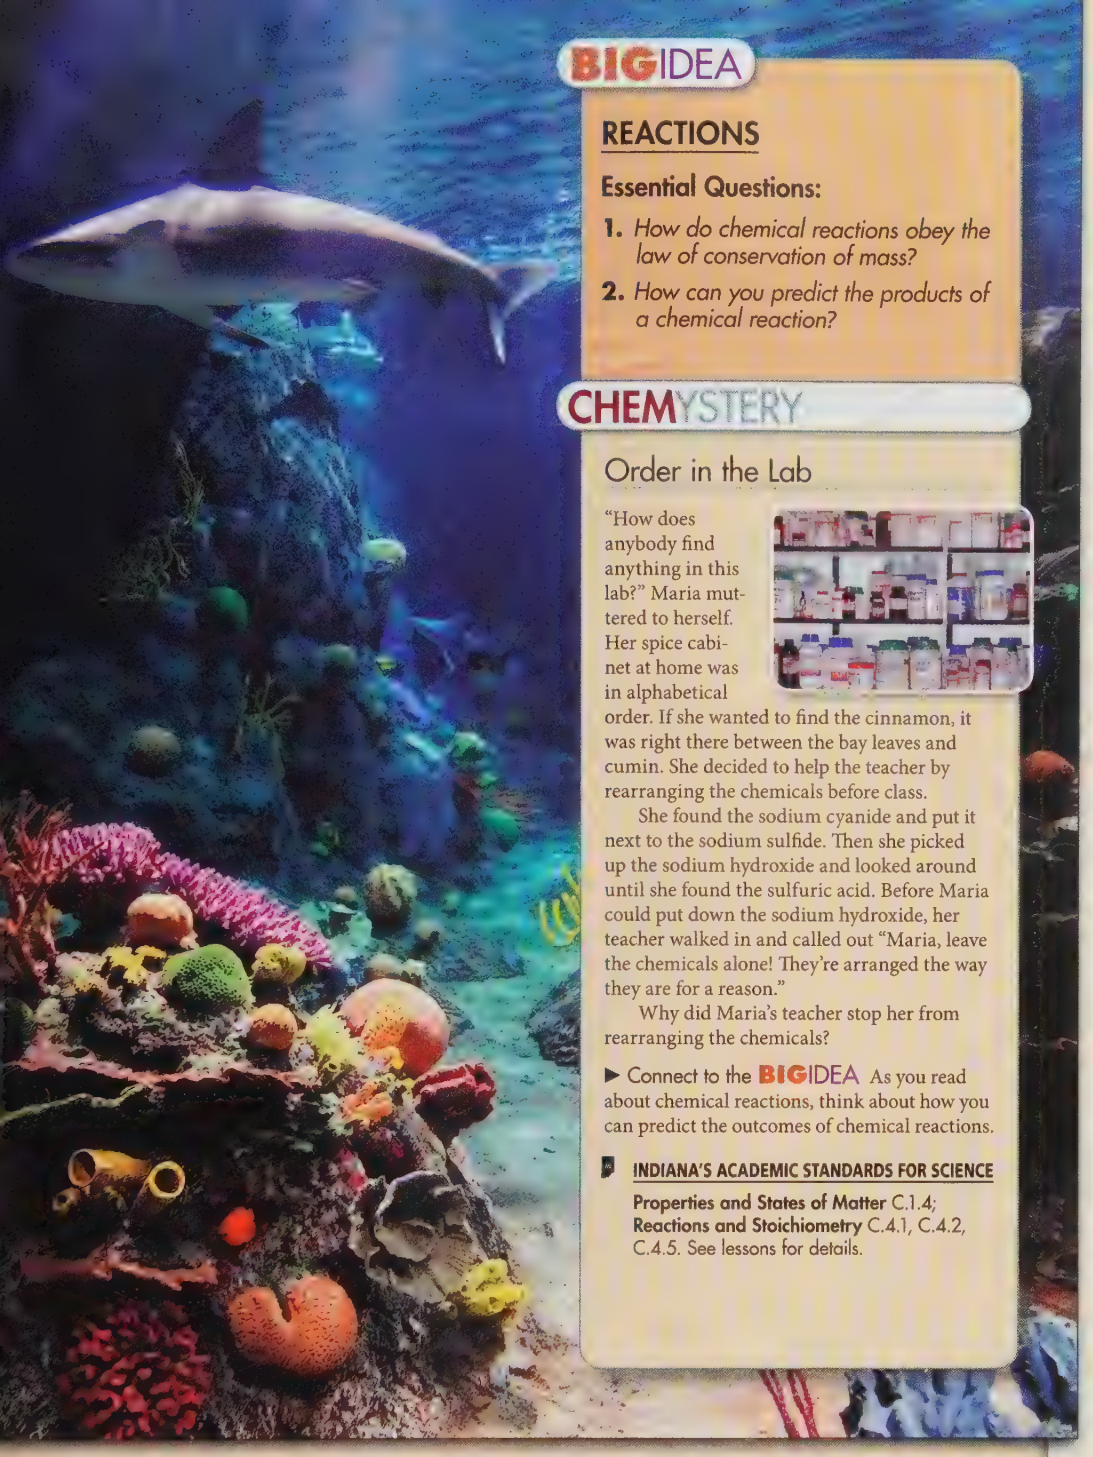
Reef aquariums like this one use an aqueous solution of calcium hydroxide to provide calcium for marine animals such as snails and coral.

344

Focus on ELL

1 CONTENT AND LANGUAGE Begin the lesson by writing the word *reaction* on the board and defining it as "a response to another event." As a class, create a list of familiar types of reactions on the board, such as emotional, nuclear, light, and reflex.



BEGINNING

LOW Have students create drawings representing reactions they have experienced.

HIGH Have students copy the list created by the class and check off the reactions with which they are familiar.

INTERMEDIATE: LOW/HIGH Using the list created by the class, students should form groups of reactions that have characteristics in common.

ADVANCED: LOW/HIGH Have each student write a journal entry describing a reaction he or she had to an event.

BIGIDEA

REACTIONS

Essential Questions:

1. *How do chemical reactions obey the law of conservation of mass?*
2. *How can you predict the products of a chemical reaction?*

CHEMYSTERY

Order in the Lab

"How does anybody find anything in this lab?" Maria muttered to herself. Her spice cabinet at home was in alphabetical order. If she wanted to find the cinnamon, it was right there between the bay leaves and cumin. She decided to help the teacher by rearranging the chemicals before class.

She found the sodium cyanide and put it next to the sodium sulfide. Then she picked up the sodium hydroxide and looked around until she found the sulfuric acid. Before Maria could put down the sodium hydroxide, her teacher walked in and called out "Maria, leave the chemicals alone! They're arranged the way they are for a reason."

Why did Maria's teacher stop her from rearranging the chemicals?

▶ Connect to the BIGIDEA As you read about chemical reactions, think about how you can predict the outcomes of chemical reactions.

INDIANA'S ACADEMIC STANDARDS FOR SCIENCE

Properties and States of Matter C.1.4; **Reactions and Stoichiometry** C.4.1, C.4.2, C.4.5. See lessons for details.

Introduce the Chapter

CONNECTION TO FOOD Students may not realize that they experience chemical reactions frequently each day. Use the activities to demonstrate some chemical reactions. You will need an effervescent tablet and a glass of water. Drop the tablet into the water so that students can see the bubbles. **Ask** What tells you this is a chemical reaction? *(gas bubbles)*

You will need an effervescent tablet and a glass of water. Drop the tablet into the so that students can see the bubbles. **Ask** What tells you that a reaction is taking place? (bubbles formed) Show students a photo of a pizza. **Ask** What tells you that a chemical reaction took place? (change in color, odor, and production of gas to raise the dough) You can also show students a cut apple that has turned brown. **Ask** What tells you that a chemical reaction took place? (change in color)

What are some signs that a reaction is taking place? *(a color change reaction)*

UbD

Understanding by Design

Students are building toward describing chemical reactions by applying an overall knowledge of reactions.

PERFORMANCE GOALS At the end of Chapter 11, students will be able to answer the essential questions by applying their knowledge of chemical reactions. Students will also be able to write and balance chemical equations.

ESSENTIAL QUESTIONS Read the essential questions aloud. **Ask** What does *conservation of mass* mean? *(Mass is neither produced nor lost.)* **Ask** What would this mean for a chemical reaction? *(The amount of mass after the reaction equals the amount before the reaction.)* **Ask** What is a *product* of a chemical reaction? *(a chemical that is produced during the reaction)*

BIGIDEA Use the photo of the reef aquarium to help students connect to the concepts they will learn in this chapter. Activate prior knowledge by asking students if they have ever seen coral like that in the photo. Explain that the hard skeletons of coral animals are made of calcium carbonate. **Ask** Where do you think coral animals get the calcium they need to make the skeletons? *(They use calcium ions in seawater.)* Have students read the photo caption. **Ask** How do you think the calcium hydroxide changes to calcium ions the coral animals can use? *(A chemical reaction between calcium hydroxide and water* releases calcium ions.*)*

CHEMYSTERY Have students read over the CHEMystery. Connect the CHEMystery to the Big Idea of Reactions by explaining that certain chemicals are more likely to react with each other and produce new substances. As a result, it is important not to store them side-by-side. The teacher had the chemicals arranged in a certain order to take prevent these chemicals from coming in contact with each other. Have students predict what might have happened if Maria had placed the sodium hydroxide next to the wrong chemical. As a hint, have them consider the chemicals that Maria had already rearranged.

LESSON 11.1

Key Objectives

11.1.1 DESCRIBE how to write a skeleton equation.

11.1.2 DESCRIBE the steps for writing and balancing a chemical equation.

Additional Resources

Engage

CHEMISTRY & YOU Have students study the photograph and read the text. Discuss reasons as to why there is an interest in producing hydrogen fuel-cell cars. Write the word equation for the reaction of hydrogen with oxygen to produce water. **Ask** Do you think there is a simpler way to write chemical equations? *(Yes, describe the reaction using chemical symbols of the elements and chemical formulas of compounds.)*

Activate Prior Knowledge

Ask What are the differences between molecular compounds and ionic compounds? *(Molecular compounds are composed of nonmetallic elements. Ionic compounds are composed of a metal cation and an anion.)* **Ask** How are chemical compounds represented? *(By chemical formulas that show the kinds and numbers of atoms in each molecule or formula unit.)*

IN ACADEMIC STANDARDS for SCIENCE

- Develop explanations based on reproducible data and observations gathered during laboratory investigations.
- Clearly communicate their ideas and results of investigations verbally and in written form using tables, graphs, diagrams, and photographs.

C.1.4 Describe physical and chemical changes at the molecular level.

Also covered C.4.1, C.4.2

11.1 Describing Chemical Reactions

C.1.4 Physical and chemical changes; **C.4.1** Predict products; **C.4.2** Balance chemical equations

CHEMISTRY & YOU

Q: *How is a chemical reaction going to change the way you drive?* You've probably heard about hydrogen fuel-cell cars. Fuel cells produce electricity through a chemical reacton without any of the combustion that you find in typical gasoline engines. In this lesson, you'll learn how to write and balance the equations that represent chemical reactions.

Key Questions

How do you write a skeleton equation?

What are the steps for writing and balancing a chemical equation?

Vocabulary

- chemical equation
- skeleton equation
- catalyst
- coefficient
- balanced equation

Introduction to Chemical Equations

How do you write a skeleton equation?

Every minute of the day chemical reactions take place—both inside you and around you. After a meal, a series of chemical reactions take place as your body digests food. Similarly, plants use sunlight to drive the photosynthetic processes needed to produce plant growth. Although the chemical reactions involved in photosynthesis and digestion are different, both chemical reactions are necessary to sustain life. All chemical reactions, whether simple or complex, involve changing substances.

In a chemical reaction, one or more reactants change into one or more products. Cooking food always involves a chemical reaction. In order to bake muffins, you begin with a recipe and ingredients, as shown in Figure 11.1. The recipe tells you which ingredients to mix together and how much of each to use. Chemical reactions take place when the ingredients or reactants are mixed together and heated in the oven. The product, in this case, is a batch of muffins. Chemists use a chemical equation—a quick, shorthand notation—to convey as much information as possible about what happens in a chemical reaction.

Figure 11.1
Reactants and Products
Reactants in the ingredients undergo chemical changes to form the product, the muffins.
Observing ***What evidence shows that chemical changes have occurred?***

Focus on ELL

1 CONTENT AND LANGUAGE Have students create a chart with four columns. In the first column have them copy the key questions and the vocabulary from the beginning of the lesson. Then, have them title the second column *Answer/Definition*, the third column, *Where can I find it?* and the fourth column, *Do I know it?* As you proceed through the lesson, encourage students to fill in column two and three of the chart. At the end of the lesson ask them to self-assess their knowledge of each question or definition by filling in the fourth column. You can use this column as a formative assessment to determine if reteaching needs to be done.

2 FRONTLOAD THE LESSON Write the word *skeleton* on the board. Discuss as a class the context in which students are most familiar with the word *skeleton*. Ask students to either discuss with their group or to write in a journal what an equation without specific amounts would be called a *skeleton equation*.

3 COMPREHENSIBLE INPUT Create a one to two word name for each of the rules for writing and balancing equations. Divide students into 6 groups, assign each group a rule and have them create a poster describing their rule. Display the posters around the room.

Figure 11.2 Examples of Reactions
Three common chemical reactions are shown below.

Iron turns to red-brown rust (iron(III) oxide) in the presence of oxygen.

Water and oxygen form when hydrogen peroxide is poured on a cut.

The products of burning methane are carbon dioxide and water.

Word Equations How do you describe what happens in a chemical reaction? Recall from Chapter 2 the shorthand method for writing a description of a chemical reaction. In this method, the reactants were written on the left and the products on the right. An arrow separated them. You read the arrow as *yields, gives,* or *reacts to produce.*

$$\text{Reactants} \longrightarrow \text{products}$$

How could you describe the rusting of iron shown in Figure 11.2a? You could say: "Iron reacts with oxygen to produce iron(III) oxide (rust)." Although that is a perfectly good description, it's quicker to identify the reactants and product by means of a word equation.

$$\text{Iron} + \text{oxygen} \longrightarrow \text{iron(III) oxide}$$

In a word equation, write the names of the reactants to the left of the arrow, separated by plus signs; write the names of the products to the right of the arrow, also separated by plus signs. Notice that no plus sign is needed on the product side of this equation because iron(III) oxide is the only product.

Have you ever poured the antiseptic hydrogen peroxide on an open cut? Bubbles of oxygen gas form rapidly, as shown in Figure 11.2b. The production of a new substance, a gas, is evidence of a chemical change. Two new substances are produced in this reaction, oxygen gas and liquid water. You could describe this reaction by saying, "Hydrogen peroxide decomposes to form water and oxygen gas." But, you could also write a word equation.

$$\text{Hydrogen peroxide} \longrightarrow \text{water} + \text{oxygen}$$

When you light a burner on your stove, methane gas bursts into flames and produces the energy needed to heat your soup. Methane is the major component of natural gas, a common fuel for heating homes and cooking food. The burning of methane, as shown in Figure 11.2c, is a chemical reaction. How would you write the word equation for this reaction? Burning a substance typically requires oxygen, so methane and oxygen are the reactants. The products are water and carbon dioxide. Thus, the word equation is as follows:

$$\text{Methane} + \text{oxygen} \longrightarrow \text{carbon dioxide} + \text{water}$$

HYDROGEN PEROXIDE Louis Jacques Thenard (1777–1857), a French chemist, is credited with discovering hydrogen peroxide. Students are likely familiar with the bleaching agent abilities of hydrogen peroxide, because it is used as an ingredient in hair bleach and teeth-whitening products. Students may be surprised to learn that hydrogen peroxide is sometimes used to restore the clarity of old paintings. Old paintings utilized lead-based paints, and these paints tended to darken over time (because PbS forms). Applying hydrogen peroxide to a painting removes sulfur compounds from the surface (converting PbS to $PbSO_4$), resulting in a clearer image.

Foundations for Reading

BUILD VOCABULARY Write the following chemical equation on the board and have students provide synonymous words or phrases for each of the vocabulary words as they describe the equation:

$$2H_2O_2 \xrightarrow{MnO_2} 2H_2O + O_2$$

READING STRATEGY As students read this section, have them write in their own words the sequence of steps that need to be taken to write and balance a chemical equation.

Explain

Introduction to Chemical Equations

MAKING CONNECTIONS Have students study Figure 11.1. Explain that bakers use baking soda and baking powder to make muffin batter rise during baking. Both compounds undergo chemical reactions in the batter when they become wet and are exposed to heat, producing bubbles of CO_2. Explain that the bubbles of trapped CO_2 cause the batter to rise; as the batter bakes, the bubbles leave tiny holes behind. Without the formation of CO_2, the muffins would be flat and heavy, instead of light and fluffy.

SUMMARIZE Have students create a running list in their notebooks of the types of evidence that indicate a chemical change has occurred, with an explanation of why each type of evidence indicates a chemical change.

Answers

FIGURE 11.1 The separate ingredients of the batter are now combined into one product—muffins.

Explain

USE VISUALS Direct students to Table 11.1. Make sure students understand the meaning and role of each symbol. Point out that the phase symbols provide important clues about reactions. Note that the items placed above the reaction arrow represent conditions that must be met before the reaction can take place at a reasonable pace.

USE VISUALS Direct students to Figure 11.3. Point out that although hydrogen peroxide contains the same kinds of elements as water, it has very different properties. Hydrogen peroxide is much less stable than water. Have students write the balanced chemical equation for the reaction described in the caption. Students should indicate the MnO_2 catalyst above the reaction arrow. Write the equation on the board and explain that this is an example of a decomposition reaction—a single compound is broken down into two or more products. Explain that although hydrogen peroxide is an unstable compound that readily decomposes to produce water and oxygen, it does so slowly at room temperature. Therefore, hydrogen peroxide must come in contact with a catalyst in order for the decomposition to proceed rapidly, as shown in Figure 11.3b.

APPLY CONCEPTS Tell students that frequently in nature the products of one reaction become the reactants of a subsequent reaction. As an example, use the combustion of octane (C_8H_{18}). Explain that octane is the primary ingredient of gasoline, which produces carbon dioxide and water vapor. Point out that the carbon dioxide can combine with atmospheric water vapor to produce carbonic acid (H_2CO_3), which is a component of acid rain. Ask students to brainstorm other such processes.

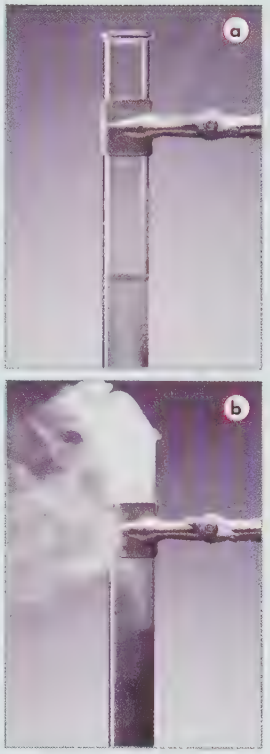

Figure 11.3
Speeding Up a Reaction
Hydrogen peroxide decomposes to form water and oxygen gas. **a.** Bubbles of oxygen appear slowly as decomposition proceeds. **b.** With the addition of the catalyst manganese(IV) oxide (MnO_2), decomposition speeds up. The white "smoke" is condensed water vapor.

Chemical Equations Word equations adequately describe chemical reactions, but they are cumbersome. It's easier to use the formulas for the reactants and products to write chemical equations. A **chemical equation** is a representation of a chemical reaction; the formulas of the reactants (on the left) are connected by an arrow with the formulas of the products (on the right). Here is a chemical equation for rusting:

$$Fe + O_2 \longrightarrow Fe_2O_3$$

Equations that show just the formulas of the reactants and products are called skeleton equations. A **skeleton equation** is a chemical equation that does not indicate the relative amounts of the reactants and products. The first step in writing a complete chemical equation is to write the skeleton equation. **To write a skeleton equation, write the chemical formulas for the reactants to the left of the yields sign (arrow) and the formulas for the products to the right.**

To add more information to the equation, you can indicate the physical states of substances by putting a symbol after each formula. Use (*s*) for a solid, (*l*) for a liquid, (*g*) for a gas, and (*aq*) for a substance in aqueous solution (a substance dissolved in water). Here is the unbalanced equation for rusting with symbols for the physical states added:

$$Fe(s) + O_2(g) \longrightarrow Fe_2O_3(s)$$

In many chemical reactions, a catalyst is added to the reaction mixture. A **catalyst** is a substance that speeds up the reaction but is not used up in the reaction. A catalyst is neither a reactant nor a product, so its formula is written above the arrow in a chemical equation. For example, Figure 11.3 shows that the compound manganese(IV) oxide ($MnO_2(s)$) catalyzes the decomposition of an aqueous solution of hydrogen peroxide ($H_2O_2(aq)$) to produce water and oxygen.

$$H_2O_2(aq) \xrightarrow{MnO_2} H_2O(l) + O_2(g)$$

Many of the symbols commonly used in writing chemical equations are listed below.

Table 11.1

Symbols Used in Chemical Equations

Symbol	Explanation
+	Separates two reactants or two products
$\longrightarrow$	"Yields," separates reactants from products
$\rightleftharpoons$	Used in place of $\longrightarrow$ for reversible reactions
(*s*), (*l*), (*g*)	Designates a reactant or product in the solid state, liquid state, and gaseous state; placed after the formula
(*aq*)	Designates an aqueous solution; the substance is dissolved in water; placed after the formula
$\xrightarrow{\Delta}$ or $\xrightarrow{heat}$	Indicates that heat is supplied to the reaction
$\xrightarrow{Pt}$	A formula written above or below the yield sign indicates its use as a catalyst (in this example, platinum).

Differentiated Instruction

ELL ENGLISH LANGUAGE LEARNERS Have students copy Table 11.1 into their vocabulary notebooks. Explain that the symbols used to write equations are universal in the scientific community; explain that all scientists use this language of symbols. Next to the symbols in their tables, students should write words from their native languages to help them quickly become familiar with the meaning of the symbols.

L1 STRUGGLING STUDENTS As students learn how to balance equations, have them, working in pairs, take turns writing equations for each other to balance. Two pairs of students may enjoy getting together for a "doubles match" in which each pair works as a team to balance equations that the opposing team creates.

L3 ADVANCED STUDENTS Challenge students to propose a hypothesis about why humans produce an enzyme that helps catalyze the decomposition of hydrogen peroxide. *(to prevent the accumulation in the body of hydrogen peroxide, a toxic byproduct of reactions involving oxygen)*

Sample Problem 11.1

Writing a Skeleton Equation

Hydrochloric acid reacts with solid sodium hydrogen carbonate. The products formed are aqueous sodium chloride, water, and carbon dioxide gas. Write a skeleton equation for this chemical reaction.

1 Analyze Identify the relevant concepts.

Write the correct formula for each substance in the reaction. Indicate the state of each substance. Separate the reactants from the products with an arrow. Use plus signs to separate the two reactants and each of the three products.

2 Solve Apply concepts to this problem.

Start with the names of reactants and products. Include their physical states.

Reactants
sodium hydrogen carbonate (solid)
hydrochloric acid (aqueous)

Products
sodium chloride (aqueous)
water (liquid)
carbon dioxide (gas)

Write the correct formula for each reactant and each product.

Reactants
$NaHCO_3(s)$ $HCl(aq)$

Products
$NaCl(aq)$ $H_2O(l)$ $CO_2(g)$

Separate the reactants from the products with an arrow. Use plus signs to separate the reactants and the products.

$NaHCO_3(s) + HCl(aq) \longrightarrow NaCl(aq) + H_2O(l) + CO_2(g)$

1. Write a sentence that describes this chemical reaction:
$Na(s) + H_2O(l) \longrightarrow NaOH(aq) + H_2(g)$

2. Sulfur burns in oxygen to form sulfur dioxide. Write a skeleton equation for this chemical reaction.

Balancing Chemical Equations

What are the steps for writing and balancing a chemical equation?

How would you write a word equation for the manufacture of bicycles? Simplify your task by limiting yourself to four major components: frames, wheels, handlebars, and pedals. Your word equation for making a bicycle could read like this.

$$\underset{\text{Reactants}}{\text{Frame} + \text{wheel} + \text{handlebar} + \text{pedal}} \longrightarrow \underset{\text{Product}}{\text{bicycle}}$$

Your word equation shows the reactants (the kinds of parts) and the product (a bicycle).

Foundations for Math

TRANSLATING WORDS TO SYMBOLS Students in algebra use key words to translate a word problem into a mathematical expression. For example, *three more than two times a number is at most one-half* translates to $3 + 2x \leq \frac{1}{2}$. The word *more* corresponds to +, the word *times* corresponds to ×, and the phrase *at most* corresponds to ≤. Explain that students should look for key words in a written description of a chemical reaction to help them translate it into a skeleton equation.

In **Sample Problem 11.1**, point out that in the first sentence, the words *reacts with* indicate that the two compounds are the reactants of the equation and should be separated by the + sign, and the word *solid* indicates the phase (*s*) of the particular reactant. Point out that in the next sentence, the words *products formed* indicate the insertion of the reaction arrow to separate the reactants from the products. And the words *aqueous* and *gas* indicate the products' phases (*aq*) and (*g*) respectively.

Explain

Sample Practice Problem

Write a skeleton molecular equation for the following chemical reaction:

Sulfuric acid reacts with solid sulfur to form sulfur dioxide gas and water.

(Sulfuric acid (aq) + Sulfur (s) → Sulfur dioxide (g) + Water (l)
$S(s) + H_2SO_4(aq) \rightarrow SO_2(g) + H_2O(l))$

Explain

Balancing Chemical Equations

APPLY CONCEPTS Review with students the law of conservation of mass. Emphasize that mass, or matter, cannot be created or destroyed. Point out that in a chemical reaction, atoms are neither created nor destroyed; all reactants must be accounted for in the products. Explain that it is because of this law that a chemical equation is not complete until it is written as a balanced equation.

Misconception Alert

Students often think that they can balance an equation by changing the subscripts in one or more of the formulas. Use the following example to show why this approach is incorrect.

$H_2(g) + O_2(g) \rightarrow H_2O(l)$ could be balanced by changing the formula of the product to H_2O_2. But H_2O_2 (hydrogen peroxide) is not the same substance as water. Therefore, the equation would describe a different reaction.

To help students overcome this misconception, have them draw boxes around the formulas for the reactants and products before they start to balance an equation. Tell them that the boxes are "off-limits" or "out of bounds." Emphasize that they cannot change any number that appears inside a box.

Answers

1. When solid sodium is dropped in water, hydrogen gas and aqueous sodium hydroxide are produced.
2. $S(s) + O_2(g) \rightarrow SO_2(g)$

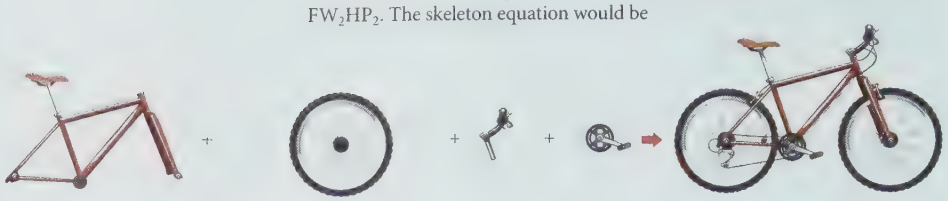
Explore

An Example of a Chemical Change

Teacher Demo

PURPOSE Students will observe a dramatic example of chemical change.

MATERIALS 150-mL glass beaker, table sugar, hood, concentrated sulfuric acid



PROCEDURE Fill a 150-mL glass beaker to the 30-mL mark with table sugar. Place the beaker in a hood, and add 30 mL of concentrated sulfuric acid, which will dehydrate the sugar.

SAFETY AND DISPOSAL The hood will remove any sulfur dioxide and carbon monoxide, which are possible byproducts of the reaction. Wear goggles, a face shield, a lab apron, and protective gloves. Use a plexiglass shield to separate the students from the reaction. As a further precaution, have students wear goggles. For disposal, wear protective gear and place the beaker and contents into a 500-mL beaker half full of water. Swirl the small beaker in the water and then neutralize using a base with a molarity of less than 1*M*. Decant the liquid and fill the large beaker halfway with water once again. Let stand overnight in a protected location, test for pH, and neutralize. Repeat if necessary. Wrap the carbon in newspaper before placing it in a wastebasket.

EXPECTED OUTCOME The carbon left behind will expand to form a porous foam cylinder as the water vapor escapes.

But if you were responsible for ordering parts to make a bicycle, this word equation would be inadequate because it does not indicate the quantity of each part needed to make one bicycle.

A standard bicycle is composed of one frame (F), two wheels (W), one handlebar (H), and two pedals (P). The formula for a bicycle would be FW_2HP_2. The skeleton equation would be

F + 1W + H + 1P ⟶ FW_2HP_2

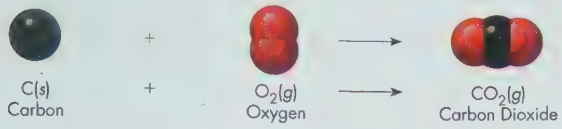
This equation is unbalanced. An unbalanced equation does not indicate the quantity of the reactants needed to make the product. A complete description of the reaction must include not only the kinds of parts involved but also the quantities of parts required.

F + 2W + H + 2P ⟶ FW_2HP_2

This equation for making a bicycle is balanced. It tells you that one frame, two wheels, one handlebar, and two pedals produce one bicycle. To balance the equation, the number 2 was placed before wheels and pedals. The number 1 is understood to be in front of *frame, handlebar,* and *bicycle.* These numbers are called **coefficients**—small whole numbers that are placed in front of the formulas in an equation in order to balance it. In this balanced equation, the number of each bicycle part on the reactant side is the same as the number of those parts on the product side. A chemical reaction is also described by a **balanced equation** in which each side of the equation has the same number of atoms of each element and mass is conserved.

Recall that John Dalton's atomic theory states that as reactants are converted to products, the bonds holding the atoms together are broken, and new bonds are formed. The atoms themselves are neither created nor destroyed; they are merely rearranged.

This part of Dalton's theory explains the law of conservation of mass: In any chemical change, mass is conserved. The atoms in the products are the same atoms that were in the reactants—they are just rearranged. Representing a chemical reaction by a balanced chemical equation is a two-step process. **To write a balanced chemical equation, first write the skeleton equation. Then use coefficients to balance the equation so that it obeys the law of conservation of mass.** In every balanced equation, each side of the equation has the same number of atoms of each element.



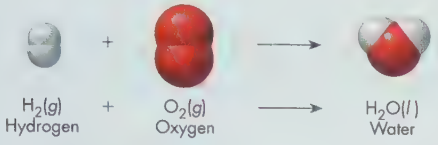
Differentiated Instruction

L3 ADVANCED STUDENTS Point out that not all chemical equations are easily balanced. Methods other than those currently shown will be used to balance more complex equations, such as those introduced in Chapter 21. Challenge students to balance the following equation: $HCl + HNO_3 \rightarrow HOCl + NO + H_2O$.

($3HCl + 2HNO_3 \rightarrow 3HOCl + 2NO + H_2O$)

LPR LESS PROFICIENT READERS Provide students with molecular model kits or foam balls of different sizes and colors. Using the balls to represent different types of atoms, students should model balancing a simple equation. Provide students with several additional unbalanced chemical equations, and have them balance the equations by using the models. Caution students to keep "atoms" in a compound together so that multiples of the entire unit are used, not multiples of just one atom in the unit.

Sometimes, though, a skeleton equation may already be balanced. For example, carbon burns in the presence of oxygen to produce carbon dioxide.

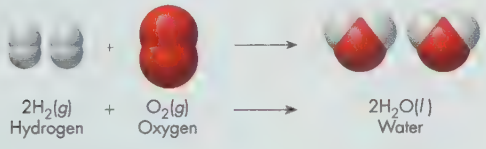


Reactants
1 carbon atom, 2 oxygen atoms

Product
1 carbon atom, 2 oxygen atoms

This equation is balanced. One carbon atom and two oxygen atoms are on each side of the equation. You do not need to change the coefficients; they are all understood to be 1.

What about the equation for the reaction of hydrogen and oxygen gas? When hydrogen and oxygen are mixed, the product of the reaction is water. The skeleton equation is as follows:



Reactants
2 hydrogen atoms
2 oxygen atoms

Product
2 hydrogen atoms
1 oxygen atom

The formulas for all the reactants and the product are correct, but this equation is not balanced. Count the atoms on both sides of the equation. Two oxygen atoms are on the reactant (left) side of the equation and only one oxygen atom is on the product (right) side. As written, the equation does not obey the law of conservation of mass, and so it does not describe quantitatively what really happens. What can you do to balance it?

To balance the equation for the reaction of hydrogen and oxygen, count the number of each kind of atom. Hydrogen is balanced, but oxygen is not. If you put the coefficient 2 in front of H_2O, the oxygen will be balanced. Now twice as many hydrogen atoms are in the product as are in the reactants. To correct this equation, put the coefficient 2 in front of H_2. Four hydrogen atoms and two oxygen atoms are on each side of the chemical equation. The equation is now balanced.

Reactants
4 hydrogen atoms
2 oxygen atoms

Products
4 hydrogen atoms
2 oxygen atoms

A few guidelines for writing and balancing equations are in the table on the next page.

CHEMISTRY & YOU

Q: *The reaction between oxygen and hydrogen in fuel cells produce the energy to power a car. What are the products of the reaction in a fuel cell that make the fuel-cell car a zero-emission car?*

See balancing equations *animated online.*

Explain

Misconception Alert

Some students think that the coefficients on both sides of the equation have to be the same in order for the number of atoms of each type to balance. Use the diagram of the formation of CO_2 on the student page to illustrate this concept. The atoms balance, but the coefficients total 2 on the left side of the equation and 1 on the right side. Convey that if the sums of the coefficients on both sides of a balanced chemical equation are the same number, it is coincidental.

CHEMISTRY & YOU Direct students to the reaction of hydrogen and oxygen to yield water. **Ask** What does "zero emission" mean based on the equation? *(Emissions are greenhouse gases and pollutants such as those produced by the combustion of fossil fuels. When hydrogen and oxygen react in a fuel cell, their only product is water.)*

Extend

Connect to TECHNOLOGY

Although fuel-cell technology sounds simple—hydrogen fuel reacts with oxygen from the air to produce water and electricity—explain to the class that in reality, the technology is fairly complicated. Have students research fuel-cell technology and note its challenges and successes in regard to powering automobiles. Instruct students to create a technological presentation explaining the advantages and disadvantages of fuel-cell technology.

UbD Check for Understanding

The Essential Question **How do chemical reactions obey the law of conservation of mass?**

Assess students' understanding of the law of conservation of mass by asking them to answer the following question:

Why do chemical equations have to be balanced when representing a chemical reaction? *(Atoms cannot be created or destroyed, so they must be conserved. Any atom that is present in a reactant must also be present in a product.)*

ADJUST INSTRUCTION If students are having trouble answering, write the law of conservation of mass on the board, along with a balanced chemical equation. Then ask them to try to answer the question again.

Explain

Balancing Chemical Equations

APPLY CONCEPTS Emphasize to students that in order to write a correct balanced chemical equation, the formulas for all reactants and products must be written correctly. Write an unbalanced chemical equation on the board, with all the formulas written correctly. Rewrite the equation with one formula written incorrectly. Identify the incorrect formula so that students consistently recognize that it is not correct. Have students balance the two equations and note the differences. Often an equation with an incorrect formula cannot be balanced.

Sample Practice Problem

Rewrite the following word equations as balanced chemical equations:

aluminum sulfate + calcium hydroxide → aluminum hydroxide + calcium sulfate

$(Al_2(SO_4)_3 + 3Ca(OH)_2 \rightarrow 2Al(OH)_3 + 3CaSO_4)$

Explore

Teacher Demo

PURPOSE Students will observe a chemical reaction and write skeleton and balanced chemical equations for the reaction.

MATERIALS 100-mL graduated cylinder, 0.1*M* copper(II) chloride solution, 400-mL beaker, metric ruler, scissors, aluminum foil

SAFETY $CuCl_2$ is an irritant.

PROCEDURE Add 200 mL of 0.1*M* copper(II) chloride solution to a 400-mL beaker. Cut a 5-cm square piece of aluminum foil. Crumple the piece of aluminum foil into a loose ball and place it in the copper solution. Ask students to note any evidence of chemical change. Write a sentence on the board that describes the chemical reaction. Have students write a skeleton equation for the reaction in their notebooks. Then have students balance the equation. Decant the liquid and flush down the drain with excess water. Dry the copper residue and use it again.

EXPECTED OUTCOME The solution will begin to produce gas, and a red-brown precipitate of copper will fall to the bottom of the beaker. The skeleton equation is the following:

$CuCl_2(aq) + Al(s) \rightarrow AlCl_3(aq) + Cu(s)$.

The balanced chemical equation is the following:

$3CuCl_2(aq) + 2Al(s) \rightarrow 2AlCl_3(aq) + 3Cu(s)$

Rules for Writing and Balancing Equations

1. Determine the correct formulas for all the reactants and products.
2. Write the skeleton equation by placing the formulas for the reactants on the left and the formulas for the products on the right with a yields sign (⟶) in between. If two or more reactants or products are involved, separate their formulas with plus signs.
3. Determine the number of atoms of each element in the reactants and products. Count a polyatomic ion as a single unit if it appears unchanged on both sides of the equation.
4. Balance the elements one at a time by using coefficients. When no coefficient is written, it is assumed to be 1. Begin by balancing elements that appear only once on each side of the equation. Never balance an equation by changing the subscripts in a chemical formula. Each substance has only one correct formula.
5. Check each atom or polyatomic ion to be sure that the number is equal on both sides of the equation.
6. Make sure all the coefficients are in the lowest possible ratio.

SampleProblem 11.2

Balancing a Chemical Equation

Students suspended copper wire in an aqueous solution of silver nitrate. They noticed a deposit of silver crystals on the copper wire when the copper reacted with the silver nitrate. They recorded the equation for this reaction but didn't balance it. Balance their equation.

$AgNO_3(aq) + Cu(s) \longrightarrow Cu(NO_3)_2(aq) + Ag(s)$

1 Analyze **Identify the relevant concepts.**

Apply the rules for balancing equations. Because the nitrate polyatomic ion appears as a reactant and a product, this ion can be balanced as a unit.

2 Solve **Apply concepts to this problem.**

Remember that a coefficient must always go in front of a compound's formula, not in the middle of it.

Balance the nitrate ion. Put a coefficient 2 in front of $AgNO_3(aq)$.

$2AgNO_3(aq) + Cu(s) \longrightarrow Cu(NO_3)_2(aq) + Ag(s)$

Balance the silver. Put a coefficient 2 in front of $Ag(s)$.

$2AgNO_3(aq) + Cu(s) \longrightarrow Cu(NO_3)_2(aq) + 2Ag(s)$

3. Balance the equation:
$CO + Fe_2O_3 \longrightarrow Fe + CO_2$

4. Write the balanced chemical equation for the reaction of carbon with oxygen to form carbon monoxide.

Foundations for Math

EQUALITY Explain that the equals sign in a mathematical equation is like the midpoint of a balance scale: Each side of the scale must hold the same mass in order for the scale to stay in balance. Likewise, the two sides of a mathematical equation must be equal for the equality to be true.

For instance, $5x^2 + x = 3x^2 + 2x + 2x^2 - x$. Combine terms to show that $5x^2 + x = 5x^2 + x$. Point out that the exponents were not altered; only the coefficients were combined.

In **Sample Problem 11.2**, explain that the yield arrow in a chemical reaction is like the equals sign in a mathematical equation. Convey that only the coefficient in front of a reactant or product can be changed when balancing an equation. Point out that if the subscript of any reactant or product were changed, this would result in a formula change that would alter the entire reaction and equality would no longer exist.

Sample Problem 11.3

Balancing a Chemical Equation

Aluminum is a good choice for outdoor furniture because it reacts with oxygen in the air to form a thin protective coat of aluminum oxide. Balance the equation for this reaction.

$$Al(s) + O_2(g) \longrightarrow Al_2O_3(s)$$

1 Analyze **Identify the relevant concepts.**
Apply the rules for balancing equations. Notice the odd number of oxygen atoms in the product.

2 Solve **Apply concepts to this problem.**

First balance the aluminum by placing the coefficient 2 in front of Al(s).

$$2Al(s) + O_2(g) \longrightarrow Al_2O_3(s)$$

Any whole number coefficient placed in front of O_2 will always give an even number of oxygen atoms on the left.

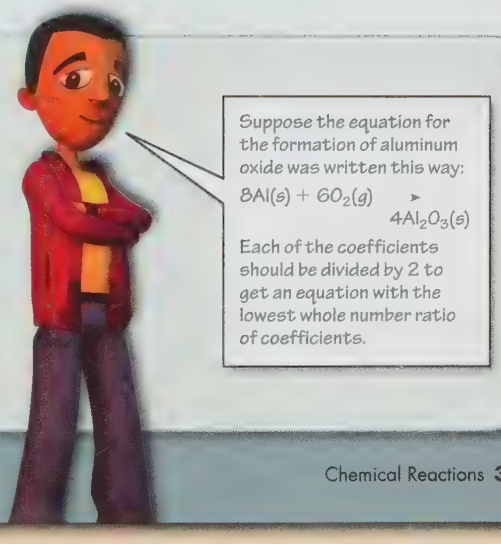
Multiply the formula with the odd number of oxygen atoms (on the right) by 2 to get an even number of oxygen atoms on the right.

$$2Al(s) + O_2(g) \longrightarrow 2Al_2O_3(s)$$

Balance the oxygens on the left by placing a 3 in front of O_2.

$$2Al(s) + 3O_2(g) \longrightarrow 2Al_2O_3(s)$$

Then rebalance the aluminum by changing the coefficient of Al(s) from 2 to 4.



$$4Al(s) + 3O_2(g) \longrightarrow 2Al_2O_3(s)$$

5. Balance each equation.

a. $FeCl_3 + NaOH \longrightarrow Fe(OH)_3 + NaCl$
b. $CS_2 + Cl_2 \longrightarrow CCl_4 + S_2Cl_2$
c. $KI + Pb(NO_3)_2 \longrightarrow PbI_2 + KNO_3$
d. $C_2H_2 + O_2 \longrightarrow CO_2 + H_2O$

6. Write and balance these equations.

a. calcium hydroxide + sulfuric acid ⟶ calcium sulfate + water
b. sodium + water ⟶ sodium hydroxide + hydrogen

Suppose the equation for the formation of aluminum oxide was written this way:

$$8Al(s) + 6O_2(g) \longrightarrow 4Al_2O_3(s)$$

Each of the coefficients should be divided by 2 to get an equation with the lowest whole number ratio of coefficients.

Focus on ELL

4 LANGUAGE PRODUCTION Have students work in groups of four to complete the Quick Lab on page 354. Make sure each group has ELLs of varied language proficiencies so that more proficient students can help less proficient ones. Have students work according to their proficiency level.

BEGINNING: LOW/HIGH Model the procedures. Have students draw a picture of the fork before and after it was placed in the solution.

INTERMEDIATE: LOW/HIGH Restate the procedures in short, simple sentences.

ADVANCED: LOW/HIGH Have these students use the think-aloud strategy when balancing the equation, in order to assist students with lower English proficiencies with this task.

Explain

MAKING CONNECTIONS Point out that balanced chemical equations can help manufacturers who use chemical processes to know how much of each reactant should be purchased and how much of each product will be made. For example, a welder might use oxygen and acetylene (C_2H_2) in a torch. Have students write a balanced chemical equation for the reaction that occurs at the torch. Water and carbon dioxide are produced. *($2C_2H_2 + 5O_2 \rightarrow 4CO_2 + 2H_2O$)* **Ask** From this balanced equation, what would be an effective acetylene:oxygen ratio for the torch? *(2:5)*

Evaluate

Informal Assessment

To evaluate students' understanding of how to write and interpret chemical equations, write two word equations on the board and have students produce skeleton equations. Then, write two unbalanced chemical equations on the board; have students balance them and describe them in words. Finally, write an equation on the board and begin to balance it by changing subscripts. When students object, ask why this approach is incorrect. Then have students complete the 11.1 Lesson Check.

Reteach

Guide students to examine the illustrations of equations throughout the lesson. Have students explain how the illustrations demonstrate the differences between a balanced and an unbalanced chemical equation. Review with students the key steps in writing balanced equations. Have them make a flowchart to describe the best way to subdivide the task.

Answers

3. $3CO + Fe_2O_3 \rightarrow 2Fe + 3CO_2$
4. $2C + O_2 \rightarrow 2CO$
5. a. $FeCl_3 + 3NaOH \rightarrow Fe(OH)_3 + 3NaCl$
   b. $CS_2 + 3Cl_2 \rightarrow CCl_4 + S_2Cl_2$
   c. $2KI + Pb(NO_3)_2 \rightarrow PbI_2 + 2\ KNO_3$
   d. $2C_2H_2 + 5O_2 \rightarrow 4CO_2 + 2H_2O$
6. a. $Ca(OH)_2 + H_2SO_4 \rightarrow CaSO_4 + 2H_2O$
   b. $2Na + 2H_2O \rightarrow 2NaOH + H_2$

Explore

QuickLab

OBJECTIVE After completing this activity, students will be able to describe and write a balanced chemical equation for a single-replacement reaction.

SKILLS FOCUS Observing, inferring, communicating results

PREP TIME 10 minutes

CLASS TIME 20 minutes

EXPECTED OUTCOME Aluminum replaces the silver in the tarnish on the fork or spoon.

ANALYZE AND CONCLUDE

1. After the reaction, the fork looks silvery, and the tarnish is gone.
2. Yes; the aluminum becomes darkened.
3. Al_2S_3
4. $3Ag_2S(s) + 2Al(s) \rightarrow 6Ag(s) + Al_2S_3(s)$

FOR ENRICHMENT Have students repeat the Quick Lab, using a piece of magnesium instead of aluminum foil. Have them compare the results and the speed of the reaction. Students will find that the reaction occurs more quickly with magnesium. After students learn about single-replacement reactions, on page 360, have them explain why the reaction proceeded more rapidly with magnesium. *(Magnesium is more active than aluminum.)*

Extend

Connect to CAREERS

Tell students that materials are classified as hazardous when the chemical reactions they undergo are potentially dangerous to humans or the environment. Explain that a hazardous materials specialist has a constantly changing career because the list of materials that are considered hazardous is constantly changing. Have students research this career and then construct a table that describes the nature of the work, educational and training requirements, employment outlook, working conditions, and other necessary information.

QuickLab

Removing Silver Tarnish

Materials

- aluminum foil, 20 cm × 20 cm
- large beaker or glass pan
- tarnished silver fork or spoon
- sodium hydrogen carbonate
- plastic tablespoon
- hot water

Procedure

1. Fill the beaker about three-quarters full of hot water and add 2 tablespoons of sodium hydrogen carbonate ($NaHCO_3$).
2. Crush the aluminum foil into a loose ball and place it in the beaker.
3. Write a brief description of the tarnished silver fork; then place it in the beaker so that it is touching the aluminum ball.
4. Allow the beaker to stand undisturbed for 30 minutes.
5. Remove the fork and aluminum ball and rinse them with water.

Analyze and Conclude

1. **Observe** Compare the silver fork with your observations before placing the fork in the water. What changes do you observe?
2. **Explain** Did a chemical reaction occur? How do you know?
3. **Explain** The tarnish on the silver fork is silver sulfide (Ag_2S). Silver becomes tarnished when it is exposed to air, egg yolk, or rubber bands. Each of these substances contains sulfur. Look carefully for a pale yellow precipitate of aluminum sulfide on the bottom of the beaker. Write the formula for aluminum sulfide.
4. **Apply Concepts** The unbalanced equation for the reaction is

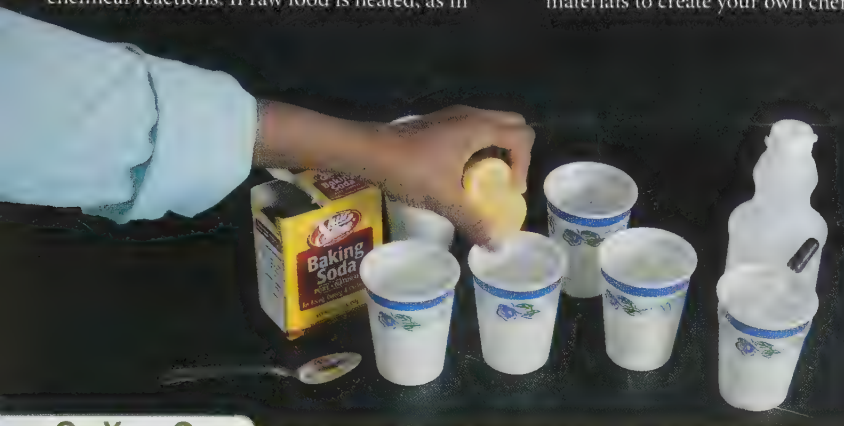
$$Ag_2S(s) + Al(s) \longrightarrow Al_2S_3(s) + Ag(s)$$

Balance the equation.

ONLINE SCIENCE

11.1 LessonCheck

7. **Explain** How do you write a skeleton equation?
8. **Summarize** Describe the steps in writing a balanced chemical equation.
9. **Describe** Write skeleton equations for these reactions.
   a. Heating copper(II) sulfide in the presence of diatomic oxygen produces pure copper and sulfur dioxide gas.
   b. When heated, baking soda (sodium hydrogen carbonate) decomposes to form the products sodium carbonate, carbon dioxide, and water.
10. **Apply Concepts** Balance the following equations:
    a. $SO_2(g) + O_2(g) \longrightarrow SO_3(g)$
    b. $Fe_2O_3(s) + H_2(g) \longrightarrow Fe(s) + H_2O(l)$
    c. $P(s) + O_2(g) \longrightarrow P_4O_{10}(s)$
    d. $Al(s) + N_2(g) \longrightarrow AlN(s)$
11. **Apply Concepts** Write and balance equations for the following reactions:
    a. Iron metal and chlorine gas react to form solid iron(III) chloride.
    b. Solid aluminum carbonate decomposes to form solid aluminum oxide and carbon dioxide gas.
    c. Solid magnesium reacts with aqueous silver nitrate to form solid silver and aqueous magnesium nitrate.



Lesson Check Answers

7. Write the formulas of the reactants to the left of the reaction arrow and the formulas of the products to the right.
8. Write the skeleton equation with the correct formulas of the reactants on the left and the correct formulas of the products on the right. Then balance the equation by using coefficients so that it obeys the law of conservation of mass.
9. a. $CuS(s) + O_2(g) \xrightarrow{heat} Cu(s) + SO_2(g)$
   b. $NaHCO_3(s) \xrightarrow{heat} Na_2CO_3(s) + CO_2(g) + H_2O(l)$
10. a. $2SO_2(g) + O_2(g) \rightarrow 2SO_3(g)$
    b. $Fe_2O_3(s) + 3H_2(g) \rightarrow 2Fe(s) + 3H_2O(l)$
    c. $4P(s) + 5O_2(g) \rightarrow P_4O_{10}(s)$
    d. $2Al(s) + N_2(g) \rightarrow 2AlN(s)$
11. a. $2Fe(s) + 3Cl_2(g) \rightarrow 2FeCl_3(s)$
    b. $Al_2(CO_3)_3(s) \rightarrow Al_2O_3(s) + 3CO_2(g)$
    c. $Mg(s) + 2AgNO_3(aq) \rightarrow 2Ag(s) + Mg(NO_3)_2(aq)$

Kitchen Chemistry

Did you know that your kitchen is a good place to study chemistry? Food preparation generally involves a large number of chemical reactions. Compounds in raw food may combine, decompose, or oxidize to give the finished product. The acids in vinegars, lemon juice, or anything acidic used to marinate meat helps break down the connective tissue of the meat through chemical reactions. If raw food is heated, as in frying and baking, chemical reactions produce many complex compounds. When you eat the cooked food, your body performs another series of chemical reactions that allow the nutrients in the food to nourish your body.

In this lesson, you learned how to describe chemical reactions and write balanced chemical equations. Now you can use ordinary kitchen materials to create your own chemical reactions.

On Your Own

1. For this activity, you'll need a few paper cups, baking soda, water, vinegar, and lemon juice. You'll also need a spoon and an eyedropper.
2. Spoon a little bit of baking soda into four cups.
3. Using the eyedropper, add a few drops of water to the first cup. Watch what happens. Then record your observations in a chart similar to the one below.
4. Repeat the process for each substance in the chart.

What Did You See?	
Substance	What's the Reaction?
Water	
vinegar	
lemon juice	
your own choice	

Take It Further

1. **Draw Conclusions** What clues tell you that a chemical reaction occurred?
2. **Apply Concepts** The skeleton equation for the reaction between baking soda and vinegar is:
$NaHCO_3 + HC_2H_3O_2 \longrightarrow NaC_2H_3O_2 + H_2O + CO_2$
Is this equation balanced? Explain.
3. **Connect to the Big Idea** How does the law of conservation of mass apply to this experiment?

Differentiated Instruction

L1 STRUGGLING STUDENTS Before assigning the On Your Own activity, discuss clues that students should look for that indicate a chemical reaction has occurred. Write the clues on the board for them to use as they make their observations. It may be helpful to have students perform the activity in class rather than at home.

LPR LESS PROFICIENT READERS Before assigning this activity, have students read each step, and then discuss it to be sure students understand the procedure before they perform it.

L3 ADVANCED STUDENTS Have students choose a type of chemical reaction that occurs in the kitchen and prepare a demonstration for the class. Students should write the reaction's chemical equation on the board as part of their demonstration.

CHEMISTRY & YOU Draw students' attention to the title of the feature and the photograph of the activity setup. Pose the following question to students: *What are some common chemical reactions that you might encounter in a kitchen?* You may need to assist students in the following ways:

- Ripening in fruits and vegetables involves chemical reactions within their cells.
- Flavors and textures change in some foods as they cook.
- Some reactions occur only when foods are cut.
- Some reactions occur only in the presence of heat, such as with double-acting baking powder.

Explain

APPLY CONCEPTS Explain that chemical reactions can be useful in cooking, but they also can have harmful effects such as food spoilage. Explain that clues that spoilage has occurred include changes in color, the formation of an unpleasant odor, and changes in taste. For example, fats in food can spoil by reacting with oxygen. Encourage students to describe examples they have seen of food spoilage. Help them connect the changes they observed to chemical reactions.

Answers

TAKE IT FURTHER

1. Bubbles formed.
2. Yes, it's balanced.
3. The law of conservation of mass states that mass cannot be created nor destroyed. This means the total mass of reactants in a chemical reaction will equal the total mass of the products. If a gas is produced during a reaction, its mass is often forgotten when calculating the final mass because the students are unable to see the gas.

LESSON 11.2

Key Objective

11.2.1 IDENTIFY the five general types of reactions.

Engage

CHEMISTRY & YOU Have students study the photograph and read the text. Ask students to predict what happens to the wax as the candle burns.

Activate Prior Knowledge

Review with students the key steps in writing balanced equations. Have them use a flowchart to describe the best way to subdivide the task.

IN ACADEMIC STANDARDS for SCIENCE

C.1.4 Describe physical and chemical changes at the molecular level.

C.4.1 Predict products of simple reactions such as synthesis, decomposition, single replacement and double replacement.

C.4.5 Describe, classify and give examples of various kinds of reactions-synthesis (combination), decomposition, single displacement, double displacement and combustion.

11.2 Types of Chemical Reactions

IN C.1.4 Physical and chemical changes; C.4.1 Predict products; C.4.5 Classify types of reactions

CHEMISTRY & YOU

Q: *What happens to the wax when you burn a candle?* You probably have noticed that you have less candle after burning than before, but you may not know that a candle will not burn unless oxygen is present. When you burn a candle, a chemical reaction called combustion takes place. In this lesson, you will learn that if you can recognize the type of reaction, you may be able to predict the products of the reaction.

Key Questions

What are the five general types of reactions?

Vocabulary

- combination reaction
- decomposition reaction
- single-replacement reaction
- activity series
- double-replacement reaction
- combustion reaction

Classifying Reactions

What are the five general types of reactions?

By classifying chemical reactions, you can more easily predict what products are likely to form. One classification system identifies five general types. **The five general types of reactions include combination, decomposition, single-replacement, double-replacement, and combustion.** Not all chemical reactions fit uniquely into only one category. Occasionally, a reaction may fit equally well into two categories. Nevertheless, recognizing a reaction as a particular type is useful. Patterns of chemical behavior will become apparent and allow you to predict the products of reactions.

Combination Reactions The first type of reaction is the combination, or synthesis, reaction. A **combination reaction** is a chemical change in which two or more substances react to form a single new substance. As shown in Figure 11.4, magnesium metal and oxygen gas combine to form the compound magnesium oxide.

$$2Mg(s) + O_2(g) \longrightarrow 2MgO(s)$$

Notice that in this reaction, as in all combination reactions, the product is a single substance (MgO), which is a compound. The reactants in this combination reaction (Mg and O_2) are two elements, which is often the case. But two compounds may also combine to form a single substance.

When a Group A metal and a nonmetal react, the product is a binary ionic compound.

$$2K(s) + Cl_2(g) \longrightarrow 2KCl(s)$$

When two nonmetals react in a combination reaction, more than one product is often possible.

$$S(s) + O_2(g) \longrightarrow SO_2(g) \text{ sulfur dioxide}$$

$$2S(s) + 3O_2(g) \longrightarrow 2SO_3(g) \text{ sulfur trioxide}$$

Focus on ELL

1 CONTENT AND LANGUAGE Write the lesson objective on the board and read it out loud slowly. Tell students the term *identify* in the objective indicates that they will answer the key question by identifying the five general types of reactions.

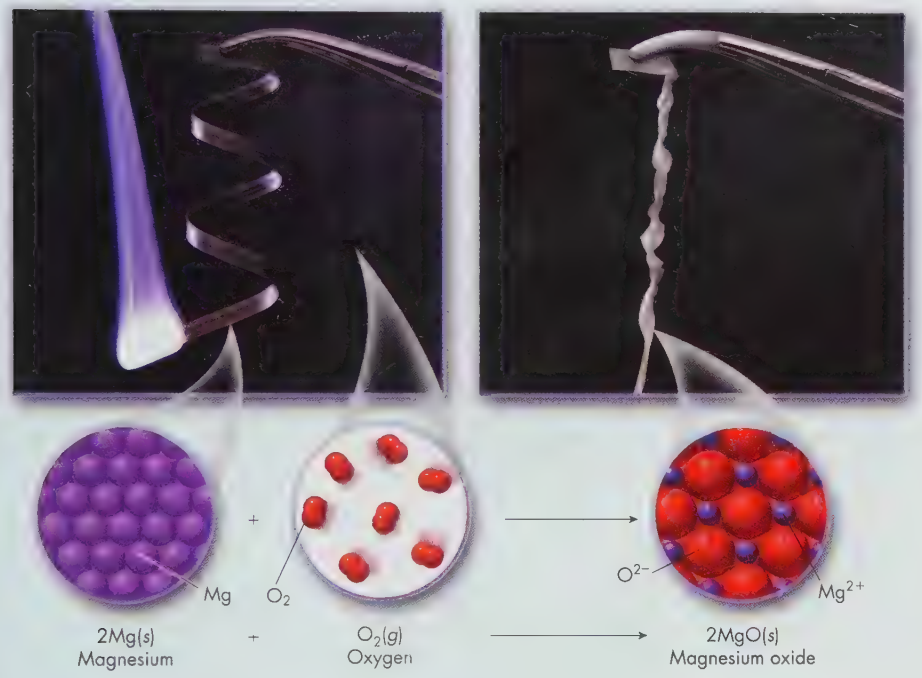
2 FRONTLOAD THE LESSON Remind students of the activity they did at the beginning of the chapter when they listed different types of reactions that are familiar to them. Ask a student to read the key question. Draw a diagram that shows the different types of reactions across the top and then under *Chemical Reactions* write the numbers 1–5. Explain to students that they are going to learn the different types of chemical reactions.

3 COMPREHENSIBLE INPUT Assign students to five groups. Assign each group a different reaction and have the students create a poster describing their reaction. Be sure they include pictures and important facts. Display the posters around the room.

More than one product may also result from the combination reaction of a transition metal and a nonmetal.

$$Fe(s) + S(s) \longrightarrow FeS(s) \text{ iron(II) sulfide}$$

$$2Fe(s) + 3S(s) \longrightarrow Fe_2S_3(s) \text{ iron(III) sulfide}$$



Some nonmetal oxides react with water to produce an acid, a compound that produces hydrogen ions in aqueous solution. You will learn about acids in Chapter 19.

$$SO_2(g) + H_2O(l) \longrightarrow H_2SO_3(aq) \text{ sulfurous acid}$$

Some metallic oxides react with water to give a base, or a compound containing hydroxide ions. Again in this case, you can use the ionic charges to derive the formula for the product.

$$CaO(s) + H_2O(l) \longrightarrow Ca(OH)_2(aq) \text{ calcium hydroxide}$$

Figure 11.4 Magnesium Ribbon
When ignited, magnesium ribbon reacts with oxygen in the surrounding air to form magnesium oxide, a white solid. This reaction is a combination reaction.

Differentiated Instruction

L3 ADVANCED STUDENTS Combination reactions are sometimes referred to as synthesis reactions. Have students research the meaning of *synthesis*. Point out that synthesis involves making a final product from other substances, but not all synthesis processes—such as those in photosynthesis—are true combination reactions.

ELL ENGLISH LANGUAGE LEARNERS Have students name different elements in their native languages and in English. Then have students list the symbols for several elements in their native languages. Point out that the names might differ, but chemical symbols are the same in any language.

L1 STRUGGLING STUDENTS Have students create a set of clues they can refer to for classifying reactions. Have students write the clues on sticky notes and attach the notes to the appropriate locations in their text.

Foundations for Reading

BUILD VOCABULARY Have students draw concept maps entitled *Types of Chemical Reactions*. Have them include all the vocabulary terms in the concept map. Ask them to explain how the name of each reaction tells what occurs in the reaction.

READING STRATEGY As students read the lesson, have them visualize the process that occurs in each type of chemical reaction. Suggest that they sketch their visualizations.

Explain

Classifying Reactions

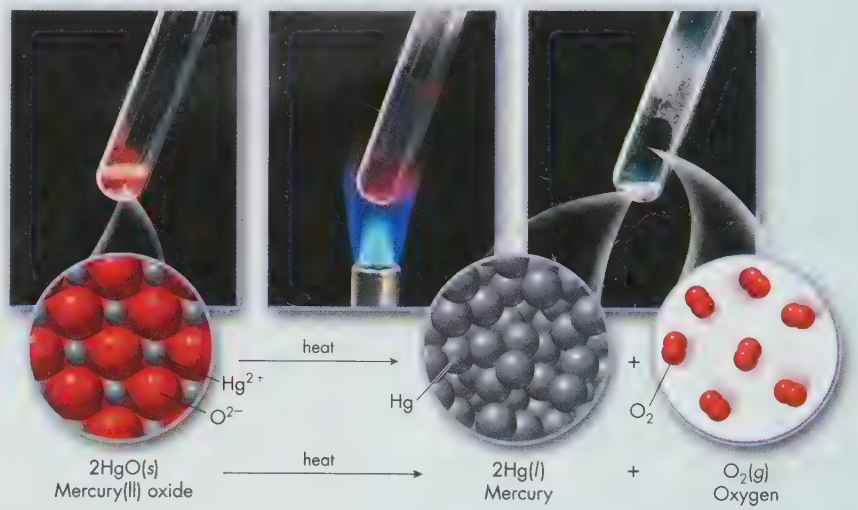
USE VISUALS Direct students' attention to Figure 11.4. Have students study the photographs. Point out that many combination reactions release large amounts of energy. Explain that the reaction of Mg with O_2 was once used in flash photography because it releases energy in the form of a bright, white light. Then, write a number of equations for combination reactions on the board and have students practice balancing them. Rewrite some of the equations with the product on the reactant side and the reactants on the product side. **Ask** Is it possible to reverse the process? *(yes)* **Ask** What is the name of the reverse process? *(a decomposition reaction)* **Ask** Why is energy usually needed for a decomposition reaction to occur? *(Decomposition involves the breaking of bonds, which requires energy.)*

Explain

Classifying Reactions

USE A VISUAL Help students create a list of criteria for identifying compostion and decompostion reactions. For example, decompostion reactions are characterized by one molecule on the reactant side and smaller molecules or elements on the product side.

Decomposition Reactions Some chemical reactions are the opposite of combination reactions. These kinds of reactions are classified as decomposiiton reactions. When mercury(II) oxide is heated, it decomposes or breaks down into two simpler substances, as shown in Figure 11.5.



$$2HgO(s) \longrightarrow 2Hg(l) + O_2(g)$$

A **decomposition reaction** is a chemical change in which a single compound breaks down into two or more simpler products. Decomposition reactions involve only one reactant and two or more products. The products can be any combination of elements and compounds. It is usually difficult to predict the products of decomposition reactions. However, when a simple binary compound such as HgO breaks down, you know that the products must be the constituent elements Hg and O_2. Most decomposition reactions require energy in the form of heat, light, or electricity.

Did you know that a decompositon reaction happens when an automobile air bag inflates? A device that can trigger the reaction is placed into the air bag along with sodium azide pellets. When the device is triggered, the sodium azide pellets decompose and release nitrogen gas, which inflates the air bag quickly.

$$2NaN_3(s) \longrightarrow 2Na(s) + 3N_2(g)$$

Figure 11.5 Decomposition Reaction
When orange-colored mercury(II) oxide is heated, it decomposes into its constituent elements: liquid mercury and gaseous oxygen.
Compare and Contrast *How are the reactions pictured in Figures 11.4 and 11.5 similar? How are they different?*

UbD Check for Understanding

BIGIDEA REACTIONS Assess students' knowledge about classifying chemical reactions by directing students to answer the following question with a written explanation or an illustrated example.

How can you tell the difference between a combination reaction and a decomposition reaction? *(A combination reaction forms one product from two or more substances, and a decomposition reaction takes a single compound and breaks it down into simpler compounds or elements.)*

ADJUST INSTRUCTION If students are having trouble answering, draw on the board a compare-contrast table for the two reaction types. Complete the table as a class. Then ask students to identify the key differences between the two reaction types.

Sample Problem 11.4

Writing Equations for Combination and Decomposition Reactions

Write a balanced equation for each of the following reactions.

a. Combination of copper and sulfur:

$Cu(s) + S(s) \longrightarrow$ (two reactions possible)

b. Decomposition of water:

$H_2O(l) \xrightarrow{\text{electricity}}$

1 Analyze **Identify the relevant concepts.** Two combination reactions are possible because copper is a transition metal and has more than one common ionic charge (Cu^+ and Cu^{2+}).

2 Solve **Apply concepts to this problem.**

Write the formula for the product(s) in each reaction.

a. Copper(I) sulfide $Cu_2S(s)$
Copper(II) sulfide $CuS(s)$

Note that Cu_2S and CuS represent different products from different reactions.

b. $H_2(g)$
$O_2(g)$

Write a skeleton equation for each reaction.

For Copper(I):
$Cu(s) + S(s) \longrightarrow Cu_2S(s)$
For Copper(II):
$Cu(s) + S(s) \longrightarrow CuS(s)$

$H2O(l) \xrightarrow{\text{electricity}} H_2(g) + O_2(g)$

The hydrogen is balanced but the oxygen is not. After balancing the oxygen, you must rebalance the hydrogen atoms.

Apply the rules for balancing equations.

For Copper(I):
$2Cu(s) + S(s) \longrightarrow Cu_2S(s)$ (balanced)
For Copper(II): the skeleton equation is already balanced.
$Cu(s) + S(s) \longrightarrow CuS(s)$ (balanced)

$2H_2O(l) \xrightarrow{\text{electricity}} H_2(g) + O_2(g)$
$2H_2O(l) \xrightarrow{\text{electricity}} 2H_2(g) + O_2(g)$
$2H_2O(l) \xrightarrow{\text{electricity}} 2H_2(g) + O_2(g)$

12. Write the formula for the binary compound that decomposes to the products H_2 and Br_2.

13. Complete and balance this decomposition reaction.

$HI \longrightarrow$

14. Write and balance the equation for the formation of magnesium nitride (Mg_3N_2) from its elements.

Professional Development Note

The Decomposition of Hydrogen Peroxide

Hydrogen peroxide is capable of gently cleansing wounds, but it also has the power to launch small rockets. The secret to its versatility lies in its concentration. Hydrogen peroxide solutions sold in the first-aid section of grocery stores are very dilute (3% v/v). When a dilute solution comes into contact with the broken cells of a wound, an enzyme called catalase catalyzes the decomposition of the hydrogen peroxide. The resulting bubbles of hydrogen and oxygen gas help loosen dirt and debris and bring them to the surface of the wound.

The decomposition reaction generates more than gas bubbles; it is exothermic as well. While the heat produced by a 3% solution is barely perceptible, the heat generated by highly concentrated solutions can turn water into steam. While this ability to generate heat is useful under certain circumstances, it has sometimes led to disastrous results.

Explain

Misconception Alert

Emphasize to students that decomposition reactions consist of one substance forming *two or more different substances*. Students tend to limit decomposition reactions to the decomposition of a compound into its component elements. Explain that a compound can also break down into an element and a compound or two or more compounds. Provide students with the following chemical equations as examples of decomposition reactions that result in products other than elements: $2H_2O_2 \rightarrow 2H_2O + O_2$ and $H_2CO_3 \rightarrow H_2O + CO_2$.

Sample Practice Problem

Write and balance an equation for the formation of aluminum chloride ($AlCl_3$) from its elements. *($2Al + 3Cl_2 \rightarrow 2AlCl_3$)*

Answers

FIGURE 11.5 Both involve two elements and one compound. In Figure 11.4, a compound is being formed from the elements; in Figure 11.5, a compound is being decomposed into its elements.

12. $HBr(g)$

13. $2HI(g) \rightarrow H_2(g) + I_2(g)$

14. $3Mg(s) + N_2(g) \rightarrow Mg_3N_2(s)$

Explore

Classifying Reactions

Teacher Demo

PURPOSE Students will observe single-replacement reactions.

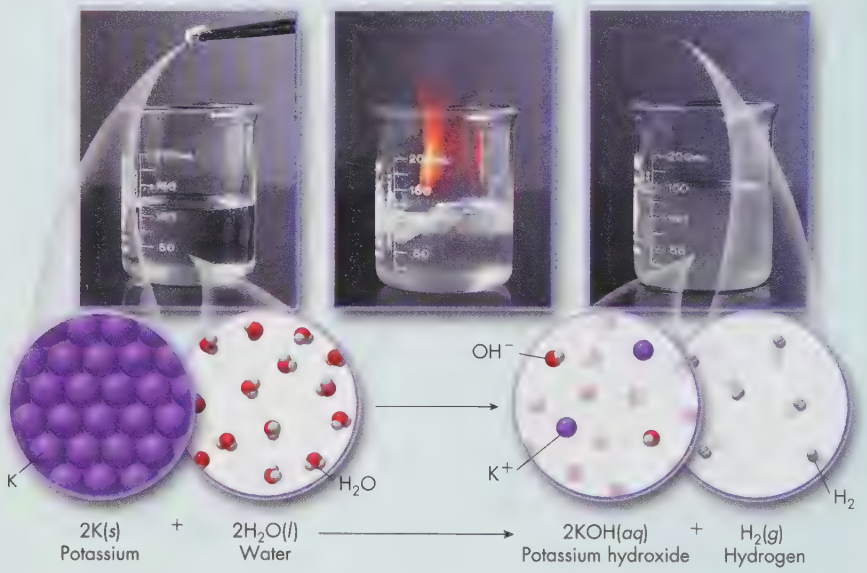
MATERIALS magnesium ribbon, 10-mL graduated cylinder, 1*M* HCl, sodium, 2 beakers, tongs, water

SAFETY HCl(*aq*) is corrosive and can cause severe burns. The piece of sodium should be no larger than a match head. Wear plastic gloves and use tongs to avoid contact between sodium and your skin.

PROCEDURE Place a 2-cm piece of magnesium ribbon in 10 mL of 1*M* HCl. Using tongs, place a small piece of sodium in 250 mL of cold water.

EXPECTED OUTCOMES In both reactions, the metal replaces hydrogen in a compound. Hydrogen gas is released. The reaction using sodium is much more dramatic and rapid than the reaction involving magnesium.

Single-Replacement Reactions Dropping a small piece of potassium into a beaker of water creates the vigorous reaction shown in Figure 11.6 The reaction produces hydrogen gas and a large quantity of heat. The released hydrogen gas can ignite explosively.



$$2K(s) + 2H_2O(l) \longrightarrow 2KOH(aq) + H_2(g)$$

Similar but less spectacular reactions can occur. For example, if you drop a piece of zinc into a solution of copper nitrate, this reaction occurs:

$$Zn(s) + Cu(NO_3)_2(aq) \longrightarrow Cu(s) + Zn(NO_3)_2(aq)$$

These equations describe two examples of single-replacement reactions. A **single-replacement reaction** is a chemical change in which one element replaces a second element in a compound. You can identify a single-replacement reaction by noting that both the reactants and the products consist of an element and a compound. In the equation above, zinc and copper change places. The reacting element Zn replaces copper in the reactant compound $Cu(NO_3)_2$. The products are the element Cu and the compound $Zn(NO_3)_2$.

Figure 11.6 Alkali Metals
The alkali metal potassium displaces hydrogen from water and forms a solution of potassium hydroxide in a single-replacement reaction. The heat of the reaction is often sufficient to ignite the hydrogen.
Inferring ***Why are alkali metals stored under mineral oil or kerosene?***

Professional Development Note

Launching the Space Shuttle

The space shuttle program ran for thirty years. During that time, each mission relied on decomposition and displacement reactions to supply the energy needed for launching the space shuttles and their payloads into space. Have students research what fuels were used to propel the space shuttle orbiters. Have volunteers describe the reactions and how the products provided the thrust necessary to launch the space vehicles.

Sample Problem 11.5

Writing Equations for Single-Replacement Reactions

Write a balanced equation for the single-replacement reaction.

$$Cl_2(aq) + NaBr(aq) \longrightarrow$$

1 Analyze **Identify the relevant concepts.** Chlorine is more reactive than bromine and displaces bromine from its compounds.

2 Solve **Apply concepts to this problem.**

Hint: You're starting with an unequal number of atoms:
- reactants
- 2 chlorine atoms
- 1 sodium atom
- 1 bromine atom
- products
- 1 chlorine atom
- 1 sodium atom
- 2 bromine atoms

Write the skeleton equation. $Cl_2(aq) + NaBr(aq) \longrightarrow NaCl(aq) + Br_2(aq)$

Apply the rules for balancing equations. $Cl_2(aq) + 2NaBr(aq) \longrightarrow 2NaCl(aq) + Br_2(aq)$ (balanced)

15. Complete the equations for these single-replacement reactions in aqueous solution. Balance each equation. Write "no reaction" if a reaction does not occur.

a. $Fe(s) + Pb(NO_3)_2(aq) \longrightarrow$
b. $Cl_2(aq) + NaI(aq) \longrightarrow$
c. $Ca(s) + H_2O(l) \longrightarrow$
d. $Zn(s) + H_2SO_4(aq) \longrightarrow$

Hint: Look at Table 11.2. Zinc displaces hydrogen from an acid and takes its place.

Whether one metal will displace another metal from a compound depends upon the relative reactivities of the two metals. The **activity series** of metals, given in Table 11.2, lists metals in order of decreasing reactivity. A reactive metal will replace any metal listed below it in the activity series. Thus, iron will displace copper from a copper compound in solution, but iron does not similarly displace zinc or calcium.

A halogen can also replace another halogen from a compound. The activity of the halogens decreases as you go down Group 7A of the periodic table—fluorine, chlorine, bromine, and iodine. Bromine is more active than iodine, so this reaction occurs:

$$Br_2(aq) + 2NaI(aq) \longrightarrow 2NaBr(aq) + I_2(aq)$$

But bromine is less active than chlorine, so this reaction does not occur:

$$Br_2(aq) + NaCl(aq) \longrightarrow \text{No reaction}$$

Table 11.2
Activity Series of Metals

	Name	Symbol
Decreasing reactivity ↓	Lithium	Li
	Potassium	K
	Calcium	Ca
	Sodium	Na
	Magnesium	Mg
	Aluminum	Al
	Zinc	Zn
	Iron	Fe
	Lead	Pb
	(Hydrogen)	(H)*
	Copper	Cu
	Mercury	Hg
	Silver	Ag

*Metals from Li to Na will replace H from acids and water; from Mg to Pb they will replace H from acids only.

Foundations for Math

USING TABLES TO SOLVE PROBLEMS Making a table is a problem-solving strategy that is often used in mathematics. A table can help students better visualize relationships in information provided in word problems, and it encourages students to look critically at the information in order to plan and develop a solution.

In **Sample Problem 11.5**, guide students to create and use a table to organize the information presented in the skeleton equation of the single-replacement reaction.

Atom	Reactants	Products
Cl	2	1
Na	1	1
Br	1	2

Point out that how easy it is to see that sodium atoms are balanced, but the chlorine and the bromine atoms are not yet balanced.

Explain

USE AN ANALOGY Direct students to Table 11.2 and review the definition of a single-replacement reaction. Explain that single-replacement reactions can be compared to cutting in at a dance. A person who is alone approaches a couple and cuts in. The person replaces one partner, who is now left alone. In a chemical reaction, however, only certain substances can replace other substances in a given compound. The activity series of metals shows which metals can replace another metal in a given compound. Review the reactions on this page. Show students how to use Table 11.2 to predict whether a reaction will occur. Direct students' attention to hydrogen's treatment in the table. Remind students that they learned in Chapter 6 that hydrogen is a nonmetal, even though it is located in period 1A of the periodic table. However, it can replace some metals and be replaced by others, so it is included in the table for reference. For this reason, hydrogen is shown enclosed by parentheses.

Sample Practice Problem

Complete the partial equation shown and then balance the equation, which is for a single-replacement reaction that takes place in aqueous solution. If a reaction does not occur, write "no reaction." (Use the activity series.)

$K(s) + H_2SO_4(aq) \rightarrow$

$(2K(s) + H_2SO_4(aq) \rightarrow K_2SO_4(aq) + H_2(g))$

Answers

FIGURE 11.6 to prevent their reaction with water vapor and oxygen in the air

15. **a.** $Fe(s) + Pb(NO_3)_2(aq) \rightarrow Fe(NO_3)_2(aq) + Pb(s)$
b. $Cl_2(aq) + 2NaI(aq) \rightarrow 2NaCl(aq) + I_2(aq)$
c. $Ca(s) + 2H_2O(l) \rightarrow Ca(OH)_2(aq) + H_2(g)$
d. $Zn(s) + H_2SO_4 \rightarrow ZoSO_4 + H_2$

Explain

Classifying Reactions

USE VISUALS Have students examine the reaction in Figure 11.7. **Ask** What characteristics do KI and $Pb(NO_3)_2$ share? *(They are both in aqueous solution, and they are both ionic compounds.)* Explain to students that a double-replacement reaction always involves two ionic compounds in aqueous solution. In addition, one of the products must be a precipitate, a gas, or a molecular compound. **Ask** Does one of the products in this reaction meet the second qualification? Why? *(Yes; PbI_2 is a solid, so it will precipitate from solution when it forms.)*

Explore

Teacher Demo

PURPOSE Students will observe double-replacement reactions.

MATERIALS equimolar solutions of $BaCl_2$, Na_2SO_4, Na_3PO_4, $CaCl_2$, $Pb(NO_3)_2$, and KI

PROCEDURE Mix equimolar solutions of the following ionic compounds: $BaCl_2$ and Na_2SO_4; Na_3PO_4 and $CaCl_2$; and $Pb(NO_3)_2$ and KI. **Ask** What evidence of a double-replacement reaction do you observe? *(a precipitate)* Write the formula of each precipitate formed in the reactions.

EXPECTED OUTCOME Precipitates of $BaSO_4$, $Ca_3(PO_4)_2$, and PbI_2 form.

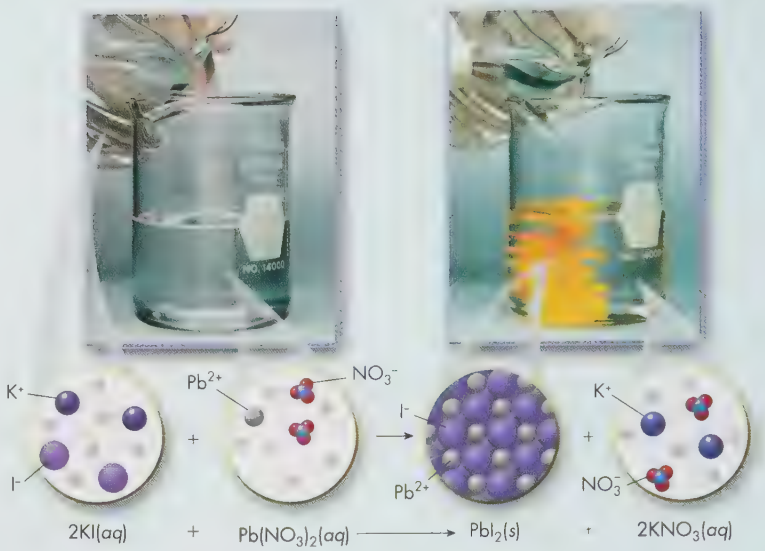


Figure 11.7 Double-Replacement Reactions
Aqueous solutions of potassium iodide and lead(II) nitrate react in a double-replacement reaction to form the yellow precipitate lead(II) iodide.

Double-Replacement Reactions Sometimes, when two solutions of ionic compounds are mixed, nothing happens. At other times, the ions in the two solutions react. Figure 11.7 shows that mixing aqueous solutions of potassium iodide and lead(II) nitrate results in a chemical reaction in which a yellow precipitate of solid lead(II) iodide is formed. Potassium nitrate, the other product of the reaction, remains in solution. This reaction is an example of a **double-replacement reaction,** which is a chemical change involving an exchange of positive ions between two compounds. Double-replacement reactions are also referred to as double-displacement reactions. They generally take place in aqueous solution and often produce a precipitate, a gas, or a molecular compound such as water. For a double-replacement reaction to occur, one of the following is usually true:

1. One of the products is only slightly soluble and precipitates from solution. For example, the reaction of aqueous solutions of sodium sulfide and cadmium nitrate produces a yellow precipitate of cadmium sulfide.

$$Na_2S(aq) + Cd(NO_3)_2(aq) \longrightarrow CdS(s) + 2NaNO_3(aq)$$

2. One of the products is a gas. Poisonous hydrogen cyanide gas is produced when aqueous sodium cyanide, also a poison, is mixed with sulfuric acid.

$$2NaCN(aq) + H_2SO_4(aq) \longrightarrow 2HCN(g) + Na_2SO_4(aq)$$

3. One product is a molecular compound such as water. Combining solutions of calcium hydroxide and hydrochloric acid produces water.

$$Ca(OH)_2(aq) + 2HCl(aq) \longrightarrow CaCl_2(aq) + 2H_2O(l)$$

UbD

Check for Understanding

The Essential Question **How can you predict the products of chemical reactions?**

Assess students' understanding of how to predict the products of chemical reactions by having them use the activity series shown in Table 11.2 to answer the following questions:

- What will happen if a piece of iron is placed in a solution of lead(II) nitrate? *(Iron will displace lead.)*
- What will happen if a piece of aluminum is placed in a solution of calcium chloride? *(Nothing will happen because Al will not displace Ca.)*

ADJUST INSTRUCTION If students have difficulty answering, project or write Table 11.2 on the board. Using a think-aloud strategy, demonstrate how to answer the first question by deciding whether iron will displace lead. As a class, work through the answer to the second question. Then provide additional practice using Table 11.2 until students are comfortable predicting reaction products.

Sample Problem 11.6

Writing Equations for Double-Replacement Reactions

A precipitate of barium carbonate is formed when aqueous solutions of barium chloride react with potassium carbonate. Write a balanced chemical equation for the double-replacement reaction.

$$K_2CO_3(aq) + BaCl_2(aq) \longrightarrow$$

1 Analyze **Identify the relevant concepts.**
The driving force behind the reaction is the formation of a precipitate. Write correct formulas of the products using ionic charges. Then balance the equation.

2 Solve **Apply concepts to this problem.**

Write the skeleton equation. $K_2CO_3(aq) + BaCl_2(aq) \longrightarrow KCl(aq) + BaCO_3(s)$

Apply the rules for balancing equations. $K_2CO_3(aq) + BaCl_2(aq) \longrightarrow 2KCl(aq) + BaCo_3(s)$ (balanced)

16. Write the products of these double-replacement reactions. Then balance each equation.

a. $NaOH(aq) + Fe(NO_3)_3(aq) \longrightarrow$ (Iron(III) hydroxide is a precipitate.)
b. $Ba(NO_3)_2(aq) + H_3PO_4(aq) \longrightarrow$ (Barium phosphate is a precipitate.)
c. $FeS(s) + HCl(aq) \longrightarrow$ (Hydrogen sulfide gas (H_2S) is formed.)

17. Write a balanced equation for each reaction.

a. $KOH(aq) + H_3PO_4(aq) \longrightarrow$ (Water is formed.)
b. $AgNO_3(aq) + NaCl(s) \longrightarrow$ (Silver chloride is a precipitate.)
c. $Ca(OH)_2(aq) + H_3PO_4(aq) \longrightarrow$ (Water is formed.)
d. $KI(aq) + Pb(NO_3)_2(aq) \longrightarrow$ (Lead(II) iodide is a precipitate.)
e. $H_2SO_4(aq) + Al(OH)_3(aq) \longrightarrow$ (Water is formed.)

Hint: Use ionic charges to write the correct formula of the other product.

Combustion Reactions The flames of a campfire, candle, or a gas grill are evidence that a combustion reaction is taking place. A **combustion reaction** is a chemical change in which an element or a compound reacts with oxygen, often producing energy in the form of heat and light. A combustion reaction always involves oxygen as a reactant. Often the other reactant is a hydrocarbon, which is a compound composed of hydrogen and carbon. The complete combustion of a hydrocarbon produces carbon dioxide and water. But if the supply of oxygen is limited during a reaction, the combustion will not be complete. Elemental carbon (soot) and toxic carbon monoxide gas may be additional products.

Foundations for Math

COEFFICIENTS As a class, compare and contrast how coefficients are used in mathematical equations and chemical equations. Point out that a coefficient in front of a variable term such as $3x$ represents the expression "3 times x." A coefficient in front of a chemical formula such as 2KCl represents the number of molecules of that compound, in this case 2. In both mathematical and chemical equations, if a coefficient is not present, the number 1 is understood. (Convey that this is also true for subscripts in chemical equations.)

Explain that the balanced chemical equation in **Sample Problem 11.6** is the same as the following expanded equation:

$$1K_2C_1O_3(aq) + 1Ba_1Cl_2(aq) \rightarrow 2K_1Cl_1(aq) + 1Ba_1C_1O_3(aq)$$

As students are sure to note, using ones as coefficients and subscripts makes the equation more difficult to read, thus defeating the purpose of using chemical symbols rather than words to express the events in a chemical reaction.

Sample Practice Problem

Write a balanced equation for the double-replacement reaction.

$K_2CrO_4(aq) + Ba(NO_3)_2(aq) \rightarrow$ (Barium chromate is a precipitate.)

($K_2CrO_4(aq) + Ba(NO_3)_2(aq) \rightarrow BaCrO_4(s) + 2KNO_3(aq)$)

Explain

START A CONVERSATION Ask students to consider the three things necessary for a fire to burn. *(fuel, oxygen, and energy to initiate combustion)* **Ask** Why is it not safe to use a single kind of fire extinguisher on all fires? *(A fire extinguisher that controls one type of fire may actually enhance other types of combustion reactions. For example, water is not sprayed on burning magnesium because the intense heat can decompose water, producing flammable hydrogen and oxygen gases.)*

MAKE A CONNECTION Discuss with students the requirements of a gas that might be used to put out a fire. Explain that the gas cannot itself burn or support the combustion of another material; it also must be heavier than air so that it will settle on a fire, depriving it of oxygen. Discuss some specific gases in terms of these factors. For example, nitrogen and helium are relatively nonreactive, but they are not heavy enough; hydrogen and methane will burn; oxygen supports the burning of the fuel; carbon dioxide will not burn or support combustion and is heavier than air. **Ask** Is a piece of paper combustible? Is it flammable? *(Paper is combustible but not flammable.)* Explain that these two terms are often used synonymously, but *combustible* means that the material will burn, and *flammable* means a material may easily burst into flame.

Answers

16. **a.** $3NaOH(aq) + Fe(NO_3)_3(aq) \rightarrow Fe(OH)_3(s) + 3NaNO_3(aq)$
b. $3Ba(NO_3)_2(aq) + 2H_3PO_4(aq) \rightarrow Ba_3(PO_4)_2(s) + 6HNO_3(aq)$
c. $FeS(s) + HCl(aq) \rightarrow FeCl_2(s) + H_2S(g)$

17. **a.** $3KOH(aq) + H_3PO_4(aq) \rightarrow K_3PO_4(aq) + 3H_2O(l)$
b. $AgNO_3(aq) + NaCl(s) \rightarrow AgCl(s) + NaN)_3(aq)$
c. $Ca(OH)_2 + H_3PO \rightarrow Ca_3(PO_4)_2 + H_2O$
d. $KI(aq) + Pb(NO_3)_2 \rightarrow PbI_2(s) + 2KNO_3(aq)$
e. $3H_2SO_4(aq) + 2Al(OH)_3(aq) \rightarrow Al_2(SO_4)_3(aq) + 6H_2O(l)$

Explain

CHEMISTRY & YOU Read the question. Ask students if their predictions about what happens as candles burns was correct.

START A CONVERSATION Point out to students that an important product of most combustion reactions is energy, which is usually in the form of heat or light. Emphasize as well that one of the reactants must be oxygen. Relate this fact to everyday experience by recalling how removing oxygen from a combustion reaction—for example, snuffing out a candle—causes the reaction to stop.

CRITICAL THINKING Ask students to infer why it is important that combustion reactions, such as those used to heat a home or run an automobile, take place in properly ventilated areas. *(Without proper ventilation and enough available oxygen, the combustion may be incomplete, and poisonous carbon monoxide may be produced.)*

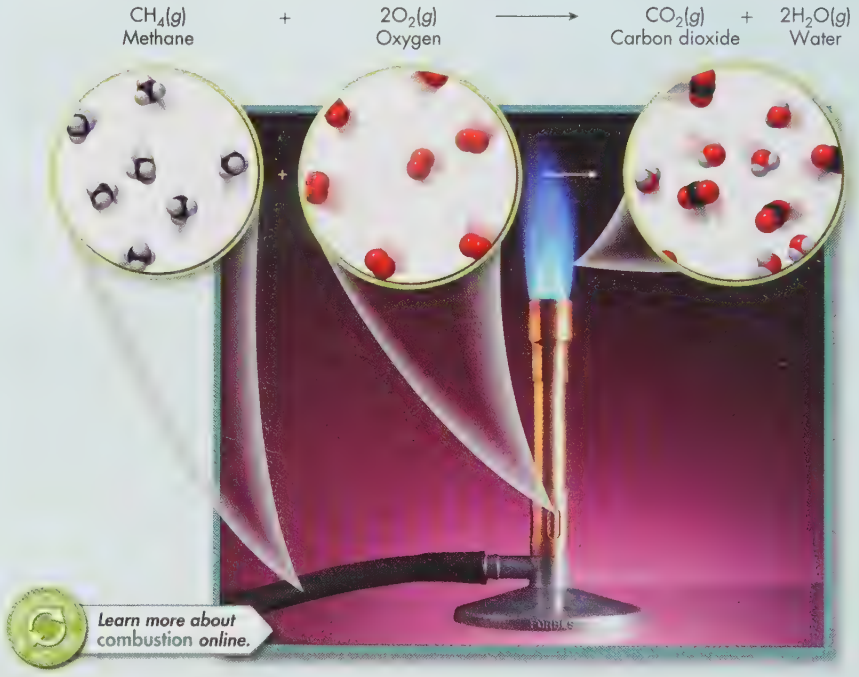
USE VISUALS Have students study Figure 11.8. Remind them that the complete combustion of a hydrocarbon, such as methane, always produces water, carbon dioxide, heat, and light. Use a disposable lighter to show students the combustion of butane. Ask students to write the balanced equation for the combustion of butane (C_4H_8). Have them use the diagram and chemical equation on this page as an aid.

MAKE A CONNECTION Explain that some combustion reactions are also combination reactions in which an element or a compound combines with oxygen to form a single product plus energy. For example: $2Mg(s) + O_2(g) \rightarrow 2MgO(s)$, and $4Fe(s) + 3O_2(g) \rightarrow 2Fe_2O_3(s)$.

CHEMISTRY & YOU

Q: *Materials such as candle wax contain hydrogen and carbon. One type of wax has a formula of $C_{25}H_{52}$. The wax reacts with oxygen in the air. So, what happens to the wax as it burns?*

The complete combustion of a hydrocarbon releases a large amount of energy as heat. That's why hydrocarbons such as methane (CH_4), propane (C_3H_8), and butane (C_4H_{10}) are important fuels. The combination reaction for methane is shown in Figure 11.8. Gasoline is a mixture of hydrocarbons that can be approximately represented by the formula C_8H_{18}. The complete combustion of gasoline in a car engine is shown by this equation.



$$2C_8H_{18}(l) + 25O_2(g) \longrightarrow 16CO_2(g) + 18H_2O(g)$$

The reactions between oxygen and some elements other than carbon are also examples of combustion reactions. For example, both magnesium and sulfur will burn in the presence of oxygen. As you look at these combustion equations, notice that the reactions could also be classified as combination reactions.

$$2Mg(s) + O_2(g) \longrightarrow 2MgO(s)$$

$$S(s) + O_2(g) \longrightarrow SO_2(g)$$

Figure 11.8 Methane Gas
Methane gas reacts with oxygen from the surrounding air in a combustion reaction to produce carbon dioxide and water.
Infer *What else is produced in this reaction?*

Differentiated Instruction

ELL ENGLISH LANGUAGE LEARNERS Make sure that students understand clearly the five terms that describe general types of chemical reactions: *combination, decomposition, single-replacement, double-replacement,* and *combustion*. Help them to spell and pronounce each term as well as to define it. Encourage them to ask questions about any term they do not fully understand.

L1 STRUGGLING STUDENTS Provide students with general statements that represent each of the first four types of chemical reactions discussed in this lesson, such as $X + Y \rightarrow XY$ for a combination reaction, $XY \rightarrow X + Y$ for a decomposition reaction, $X + CD \rightarrow XD + C$ for a single-displacement reaction, and $AB + CD \rightarrow AD + CB$ for a double-displacement reaction. Tell students that they can compare actual reactions to these general statements to help them identify the reaction type.

Sample Problem 11.7

Writing Equations for Combustion Reactions

An alcohol lamp often uses ethanol as its fuel. Write a balanced equation for the complete combustion of ethanol.

$C_2H_6O(l)$

1 Analyze **Identify the relevant concepts.**
Oxygen is the other reactant in a combustion reaction. The products are CO_2 and H_2O.

2 Solve **Apply concepts to this problem.**

Write the skeleton equation. $C_2H_6O(l) + O_2(g) \longrightarrow CO_2(g) + H_2O(g)$

Apply the rules for balancing equations. $C_2H_6O(l) + 3O_2(g) \longrightarrow 2CO_2(g) + 3H_2O(g)$ (balanced)

18. Write a balanced equation for the complete combustion of each compound.
- **a.** formaldehyde ($CH_2O(g)$)
- **b.** heptane ($C_7H_{16}(l)$)
- **c.** benzene ($C_6H_6(l)$)

19. Write a balanced equation for the complete combustion of
- **a.** glucose ($C_6H_{12}O_6(s)$)
- **b.** acetone ($C_3H_6O(l)$)
- **c.** pentanol ($C_5H_{12}O(l)$)

Now that you have learned about some of the basic reaction types, you can predict the products of many reactions. The number of elements and/or compounds reacting is a good indicator of possible reaction type and, thus, possible products.

For example, in a combination reaction, two or more reactants (elements or compounds) combine to form a single product. In a decomposition reaction, a single compound is the reactant; two or more substances are the products. An element and a compound are the reactants in a single-replacement reaction. A different element and a new compound are the products. In a double-replacement reaction, two ionic compounds are the reactants; two new compounds are the products. The reactants in a combustion reaction are oxygen and usually a hydrocarbon. The products of most combustion reactions are carbon dioxide and water.

Differentiated Instruction

L3 ADVANCED STUDENTS When hydrochloric acid (HCl) is dropped on calcium carbonate ($CaCO_3$), a double-replacement reaction occurs. **Ask** What are the products of this reaction? *($CaCl_2$ and H_2CO_3)* Neither of these products is a gas, but bubbles of gas are released during this reaction. Ask students to infer the identity of the gas. *(CO_2)* **Ask** What type of reaction could produce this gas? *(the decomposition reaction $H_2CO_3 \rightarrow H_2O + CO_2$)* Explain that geologists often make use of this pair of reactions to test rock samples for the presence of limestone, which is formed from the calcium carbonate skeletons of prehistoric corals.

Explore

Teacher Demo

PURPOSE Students will observe the combustion of iron.

MATERIALS superfine steel wool, plastic sandwich bag, balance, ring stand, utility clamp, matches

SAFETY Steel wool burns readily.

PROCEDURE Place a superfine steel wool pad in a plastic sandwich bag, measure the mass, and write the value on the board. Take the steel wool out of the bag and unfold it to full length. Clamp it to a ring stand with a utility clamp. Set the steel wool on fire. Ask students to predict what effect the burning will have on the mass of the sample. As soon as the steel wool stops burning and is cool, place the remains in the same plastic sandwich bag and measure the mass again. Write the new value on the board, next to the original mass. Discuss why the sample gained mass.

EXPECTED OUTCOMES Two elements, Fe*(s)* and $O_2(g)$, will combine in a combustion reaction to form a binary compound, Fe_2O_3. The sample will gain mass because initially only the mass of the iron is determined. During the reaction, oxygen from the air will combine with the iron.

Sample Practice Problem

Write a balanced equation for the complete combustion of propanè, C_3H_8.

($C_3H_8 + 5O_2 \rightarrow 3CO_2 + 4H_2O$)

Answers

Teacher Demo

PURPOSE Students will observe a combination reaction.

MATERIALS magnesium ribbon, large crucible, lab burner, cobalt blue glass or exposed photographic film, crucible tongs, matches or igniter

SAFETY Students should not look directly at burning magnesium. Have them observe through pieces of cobalt blue glass or exposed photographic film. Another option is to conduct the reaction inside a large, metal can.

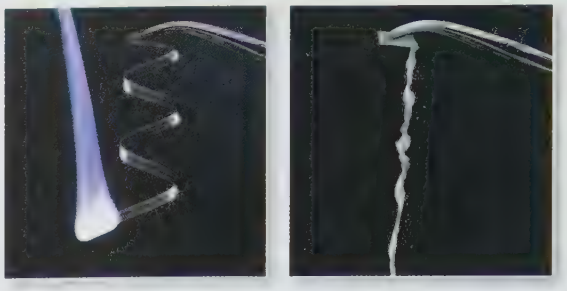
PROCEDURE Explain to students that in a combination reaction, the reactants combine to make one new product. Measure a 5- to 7-cm strip of magnesium ribbon. Light the burner. Hold one end of the magnesium ribbon with a pair of crucible tongs. Ignite the magnesium and hold it above the crucible. Ask students to note any evidence of chemical change. Have students note the condition of the residue compared to the original magnesium. The product may be disposed of in the trash.

EXPECTED OUTCOMES Metallic magnesium and oxygen gas from the air form a white powder, magnesium oxide. Other evidence of chemical change includes release of energy as heat and light. Tell students that small amounts of magnesium nitride also form.

Extend

Extend the demonstration on this page. **Ask** What are the reactants in this combination reaction? *(Mg and O_2.)* What is the product of this reaction? *(MgO)* Does this reaction obey the law of conservation of mass? Explain. *(Yes. The sum of the masses of magnesium and oxygen is equal to the mass of the magnesium oxide formed.)* Have students write the balanced equation for the reaction. *($2Mg(s) + O_2(g) \rightarrow 2MgO(s)$)* Challenge students to write the balanced equation for the formation of the small amount of magnesium nitride that forms during this reaction. *($3Mg(s) + N_2(g) \rightarrow Mg_3N_2(s)$).*

1 Combination Reaction



General Equation: R + S ⟶ RS

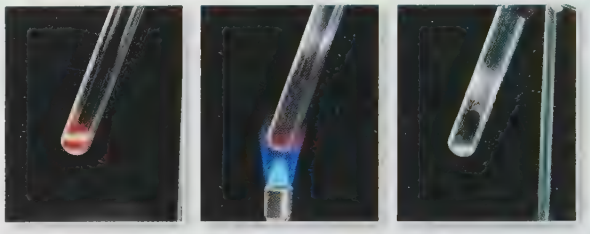
Reactants: Generally two elements, or two compounds (where at least one compound is a molecular compound)

Probable Products: A single compound

Example: Burning magnesium in air

See reactions animated online.

$2Mg(s) + O_2(g) \longrightarrow 2MgO(s)$



2 Decomposition Reaction

General Equation: RS ⟶ R + S

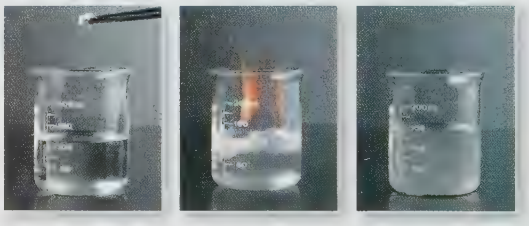
Reactants: Generally a single binary compound or a compound with a polyatomic ion

Probable Products: Two elements (for a binary compound), or two or more elements and/or compounds (for a compound with a polyatomic ion)

Example: Heating mercury(II) oxide

$2HgO(s) \longrightarrow 2Hg(l) + O_2(g)$

3 Single-Replacement Reaction



General Equation: T + RS ⟶ TS + R

Reactants: An element and a compound

In a single-replacement reaction, an element replaces another element from a compound in aqueous solution. For a single-replacement reaction to occur, the element that is displaced must be less active than the element that is doing the displacing.

Probable Products: A different element and a new compound

Example: Potassium in water

$2K(s) + 2H_2O(l) \longrightarrow 2KOH(aq) + H_2(g)$

Professional Development Note

Magnesium from Seawater

Magnesium metal is an important component of alloys used to make consumer materials. The main commercial source of Mg(s) is seawater. The Mg^{2+} ion is the third most abundant dissolved ion in the oceans. A process for isolating magnesium from seawater depends on the fact that because of a double-replacement reaction, Mg^{2+} will precipitate when OH^- is added. Students can research the commercial process.

4 Double-Replacement Reaction

General Equation: $R^+ S^- + T^+ U^- \longrightarrow R^+ U^- + T^+ S^-$

Reactants: Two ionic compounds

In a double-replacement reaction, two ionic compounds react by exchanging cations to form two different compounds.

Probable Products: Two new compounds

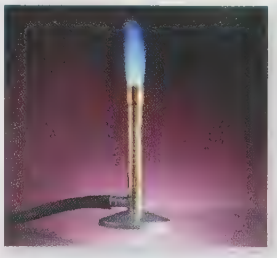
Double-replacement reactions are driven by the formation of a precipitate, a gaseous product, or water.

Example: Reaction of aqueous solutions of potassium iodide and lead(II) nitrate.

$2KI(aq) + Pb(NO_3)_2(aq) \longrightarrow PbI_2(s) + 2KNO_3(aq)$

5 Combustion Reaction

General Equation: $C_x H_y + (x + y/4)\, O_2 \longrightarrow xCO_2 + (y/2)H_2O$



Reactants: Oxygen and a compound of C, H, (O)

When oxygen reacts with an element or compound, combustion may occur.

Probable Products: CO_2 and H_2O

With incomplete combustion, C and CO may also be products.

Example: The combustion of methane gas in air

$CH_4(g) + 2O_2(g) \longrightarrow CO_2(g) + 2H_2O(g)$

11.2 LessonCheck

20. **Review** What are the five types of chemical reactions?

21. **Apply Concepts** Classify each reaction and balance the equations.

a. $C_3H_6(g) + O_2(g) \longrightarrow CO_2(g) + H_2O(g)$

b. $Al(OH)_3(s) \longrightarrow Al_2O_3(s) + H_2O(l)$

c. $Li(s) + O_2(g) \longrightarrow Li_2O(s)$

d. $Zn(s) + AgNO_3(aq) \longrightarrow Ag(s) + Zn(NO_3)_2(aq)$

22. **Identify** Which of the five general types of reaction would most likely occur, given each set of reactants? What are the probable products?

a. an aqueous solution of two ionic compounds

b. a single compound

c. two elements

d. oxygen and a compound of carbon and hydrogen

23. **Apply Concepts** Complete and balance an equation for each reaction.

a. $CaI_2(aq) + Hg(NO_3)_2(aq) \longrightarrow$ (HgI_2 precipitates.)

b. $Al(s) + Cl_2(g) \longrightarrow$

c. $Ag(s) + HCl(aq) \longrightarrow$

d. $C_2H_2(g) + O_2(g) \longrightarrow$

BIG IDEA REACTIONS

24. After wood burns, the ash weighs much less than the original wood. Explain why the law of conservation of mass is not violated in this situation.

Lesson Check Answers

20. combination, decomposition, single-replacement, double-replacement, and combustion

21. **a.** combustion; $2C_3H_6 + 9O_2 \rightarrow 6CO_2 + 6H_2O$

b. decomposition; $2Al(OH)_3 \rightarrow Al_2O_3 + 3H_2O$

c. combination; $4Li + O_2 \rightarrow 2Li_2O$

d. single-replacement; $Zn + 2AgNO_3 \rightarrow 2Ag + Zn(NO_3)_2$

22. **a.** double replacement; two different compounds

b. decomposition; two or more elements and/or compounds

c. combination; a compound

d. combustion; carbon dioxide and water

23. **a.** $CaI_2 + Hg(NO_3)_2 \rightarrow HgI_2 + Ca(NO_3)_2$

b. $2Al + 3Cl_2 \rightarrow 2AlCl_3$

c. no reaction

d. $2C_2H_2 + 5O_2 \rightarrow 4CO_2 + 2H_2O$

24. **BIG IDEA** The combustible compounds in wood react with O_2 to produce CO_2 and H_2O during combustion, leaving the non-combustible components behind as ash. The law is not violated because the total mass of the wood and O_2 before combustion is equal to the total mass of the ash, CO_2 and H_2O produced by the reaction.

Evaluate

Informal Assessment

Create a matching assessment involving types of reaction in one column and balanced chemical equations in the other column. As a challenge, write on the board only the products of combination, decomposition, and displacement reactions, and challenge students to fill in the reactants. Then have students complete the 11.2 Lesson Check.

Reteach

Help students develop a branched flowchart of chemical reactions that is similar to flowcharts used in qualitative analysis. Start by asking if there is a single reactant. If so, the reaction is a decomposition. If not, proceed to the next step. Ask if oxygen is one of the reactants. If so, the reaction is either combination or combustion. If not, proceed to the next step. Continue through the five general types of reactions.

CHEMISTRY & YOU Have students examine the photo of the collapsing building and read the caption. Lead students in discussing the use of combustion reactions in demolition. Point out that the blasting cap also relies on a combustion reaction. Pose the following question to students: *Why might an explosion be necessary to detonate dynamite?* You may need to assist students in the following ways:

- Ammonium nitrate replaced nitroglycerin in dynamite because of its greater stability.
- Ammonium nitrate is a common agricultural fertilizer that does not explode despite mixing with air as it is spread on cropland.
- Ammonium nitrate can be melted, at which point additional heat will cause it to decompose into nitrous oxide (N_2O) and water.

Explain

START A CONVERSATION Draw students' attention to the second column of text on the page. **Ask** What are the three reasons mentioned to explain why ammonium nitrate is used today instead of nitroglycerin? *(It makes dynamite stronger, safer, and cheaper.)* Explain that large manufacturing companies often employ chemists who continually research and develop new and better products. Engage students in discussing how a manufacturing company today might use chemistry research to develop an even better explosive than ammonium nitrate

Extend

Connect to PHYSICS

If possible, present a video that shows a controlled demolition of a skyscraper or sports facility and has commentary from the explosives expert taking part in the demolition. Challenge students to identify the factors that allow a relatively small amount of explosive to bring down even the largest sports facility.

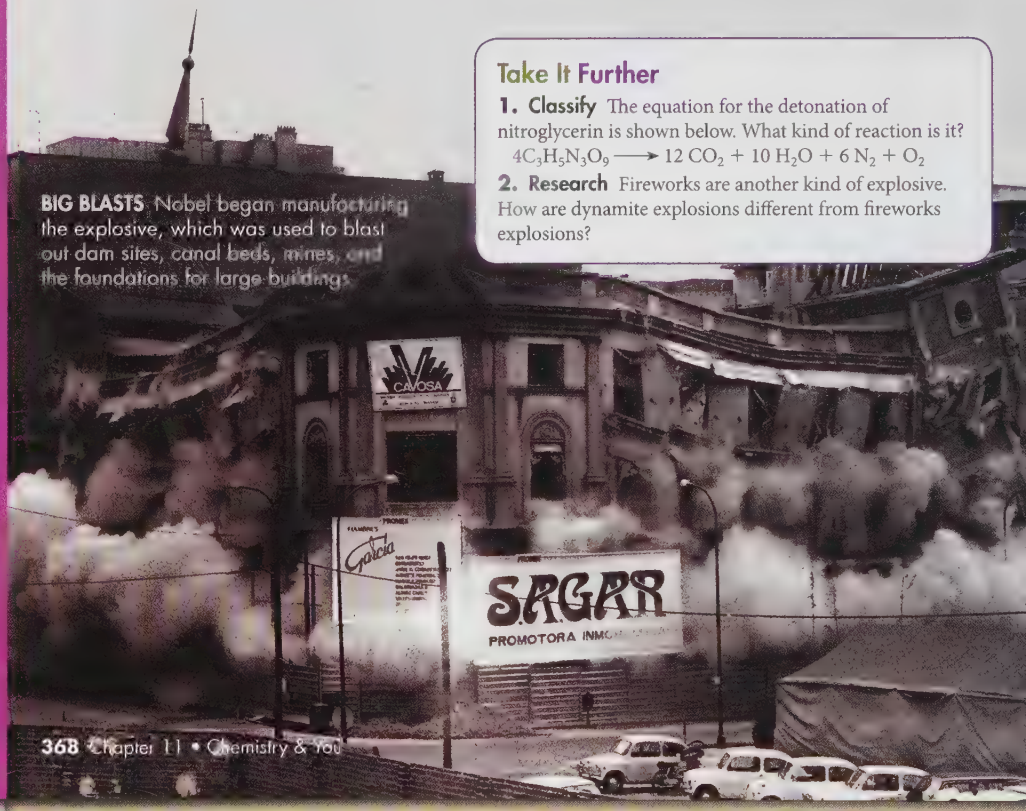
CHEMISTRY & YOU: HISTORY

The History of Dynamite

In 1846, Ascanio Sobrero added glycerol to a mixture of concentrated nitric and sulfuric acids. The resulting oily liquid, known as nitroglycerin, turned out to be such a powerful explosive that a small bottle could blow up a building. Unfortunately, it was also extremely unstable, and tended to explode after being handled roughly, or a temperature change.



Alfred Nobel (1833–1896), a Swedish chemist and industrialist, began experimenting with nitroglycerin, looking for a way to make it safe to use. In 1866, Nobel discovered that he could mix nitroglycerine with a fine sand called *kieselguhr* to turn the liquid into paste that could be shaped into rods. The rods were then packed into cylinders made of paper. He named these rods "dynamite."

Originally, Nobel marketed dynamite as Nobel's Blasting Powder.

To safely ignite dynamite and control the timing of a detonation, Nobel also invented blasting caps, which create a small explosion that triggers the larger explosion in the dynamite itself.

Today, ammonium nitrate is used in place of nitroglycerin. This dynamite is stronger, safer, and cheaper than Nobel's original invention.

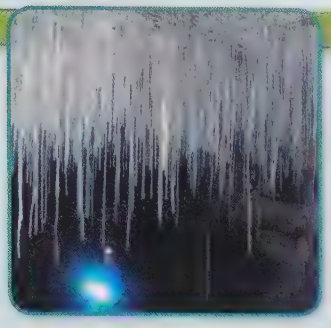
When he died in 1896, Alfred Nobel left a nine million dollar fortune to be used to fund different fields of study. The Nobel Prize is still awarded to people whose work helps humanity.

BIG BLASTS Nobel began manufacturing the explosive, which was used to blast out dam sites, canal beds, mines, and the foundations for large buildings.

Take It Further

1. Classify The equation for the detonation of nitroglycerin is shown below. What kind of reaction is it?

$$4C_3H_5N_3O_9 \longrightarrow 12\,CO_2 + 10\,H_2O + 6\,N_2 + O_2$$



2. Research Fireworks are another kind of explosive. How are dynamite explosions different from fireworks explosions?

21st Century Learning To be successful in the 21st century, students need skills and learning experiences that extend beyond subject matter mastery. The following project helps students build the following 21st Century Skills: *Creativity and Innovation; Communication and Collaboration; Initiative and Self-Direction; Productivity and Accountability.*

EXPLOSION! Pose the following challenge to your students. A demolition company has decided to use dynamite to bring down a tall building in a city. Your job is to inform people who work or live in nearby buildings about what to expect. Create an informational flyer that can be posted in the area and passed out to residents and/or businesses in the blast zone. The flyer should describe why dynamite rather than other explosives will be used for the demolition, and it should explain the type of chemical reaction involved in easy-to-understand terms. It should also explain what the explosion will be like at the site of the building and in nearby areas. The flyer should list the precautions that will be taken to protect surrounding properties, and it should include a map of the blast and safety zones.

11.3 Reactions in Aqueous Solution

C.1.4 Physical and chemical changes; C.4.1 Predict products; C.4.5 Classify types of reactions

CHEMISTRY & YOU

Q: *How did soda straws get into limestone caves?* These "soda straws" are really stalactites in a limestone cave. Soda straws grow on cave ceilings as thin-walled hollow tubes that result from chemical reactions involving water. In this lesson, you will learn to predict the formation of precipitates and write equations to describe the reactions that produce them.

Key Questions

- *What does a net ionic equation show?*
- *How can you predict the formation of a precipitate in a double-replacement reaction?*

Vocabulary

- complete ionic equation
- spectator ion
- net ionic equation

Net Ionic Equations

What does a net ionic equation show?

Your world is water based. More than 70 percent of Earth's surface is covered by water, and about 66 percent of the adult human body is water. It is not surprising, then, that many important chemical reactions take place in water—that is, in aqueous solution. The reaction of aqueous solutions of silver nitrate with sodium chloride to form solid silver chloride and aqueous sodium nitrate is a double-replacement reaction. The reaction is shown in Figure 11.9.

$$AgNO_3(aq) + NaCl(aq) \longrightarrow AgCl(s) + NaNO_3(aq)$$

The equation above reflects the way you have been writing equations involving aqueous solutions of ionic compounds. However, the equation does not show that, like most ionic compounds, the reactants and one of the products dissociate, or separate, into cations and anions when they dissolve in water.

Figure 11.9 Precipitate in a Double Replacement Reaction
A precipitate of silver chloride forms when aqueous solutions of silver nitrate and sodium chloride are mixed.
Inferring *Which ions do not participate in the reaction?*

Focus on ELL

1 CONTENT AND LANGUAGE Write the word *aqueous* on the board and explain to students that it is the adjective form of the noun *aqua*, which means "water". Remind students that aqueous solutions are solutions made from ionic or molecular compounds dissolved in water.

2 FRONTLOAD THE LESSON Review double-replacement reactions with students. Make sure that students are able to consistently identify monatomic and polyatomic ions and their associated charges by writing a few practice compounds on the board.

3 COMPREHENSIBLE INPUT Preview the equations and sample problems in the lesson. Review the four abbreviations used to indicate the states of matter of reactants and products (*aq*, *s*, *g*, and *l*). Have students list the abbreviations, with definitions, in their notebooks.

LESSON 11.3

Key Objectives

11.3.1 DESCRIBE the information found in a net ionic equation.

11.3.2 PREDICT the formation of a precipitate in a double-replacement reaction.

Engage

CHEMISTRY & YOU Point out that the formation of stalactites and stalagmites is a precipitation reaction. **Ask** What does the term *precipitation reaction* suggest about the substances that react to create these formations? *(The term precipitation reaction suggests that ions are involved in their creation.)*

Activate Prior Knowledge

Ask In a double-replacement reaction, two ions form a solid precipitate, a molecular compound, or a gas. What happens to the other ions? *(They remain dissolved in the solution.)* **Ask** What would you need to know to predict whether a precipitate forms in a double-replacement reaction? *(the solubility of all compounds that could form)*

IN ACADEMIC STANDARDS for SCIENCE

C.1.4 Describe physical and chemical changes at the molecular level.

C.4.1 Predict products of simple reactions such as synthesis, decomposition, single replacement and double replacement.

C.4.5 Describe, classify and give examples of various kinds of reactions-synthesis (combination), decomposition, single displacement, double displacement and combustion.

Foundations for Reading

BUILD VOCABULARY Help students predict the meaning of the term *net ionic equation* by exploring the meaning of phrases such as *net income* and *net worth*.

READING STRATEGY Stress that it is important to note the physical states of reactants and products in precipitation reactions.

Explain

Net Ionic Equations

APPLY CONCEPTS Explain to students that a net ionic equation differentiates between ions that react to form a solid precipitate, a gas, or water and ions that simply remain in aqueous solution. It is important to note, however, that spectator ions are not completely unaffected by the reaction. They become paired with different anions or cations than they were paired with when the reaction began.

READING SUPPORT

Build Vocabulary: *Word Origins* The word *spectator* comes from the Latin verb *spectare*, meaning "to watch." Thus, a spectator ion can be thought of as only watching a reaction, not participating. ***During a football game, what analogy can you draw to the people in the seats and the football players on the field?***

For example, when sodium chloride dissolves in water, it separates into sodium ions ($Na^+(aq)$) and chloride ions ($Cl^-(aq)$). Similarly, when dissolved in water, silver nitrate dissociates into silver ions ($Ag^+(aq)$) and nitrate ions ($NO_3^-(aq)$). You can use these ions to write a **complete ionic equation,** an equation that shows dissolved ionic compounds as dissociated free ions.

$$Ag^+(aq) + NO_3^-(aq) + Na^+(aq) + Cl^-(aq) \longrightarrow$$

$$AgCl(s) + Na^+(aq) + NO_3^-(aq)$$

Notice that the nitrate ion and the sodium ion appear unchanged on both sides of the equation. The equation can be simplified by eliminating these ions because they don't participate in the reaction.

$$Ag^+(aq) + \cancel{NO_3^-(aq)} + \cancel{Na^+(aq)} + Cl^-(aq) \longrightarrow$$

$$AgCl(s) + \cancel{Na^+(aq)} + \cancel{NO_3^-(aq)}$$

An ion that appears on both sides of an equation and is not directly involved in the reaction is called a **spectator ion.** When you rewrite an equation leaving out the spectator ions, you have the net ionic equation. The **net ionic equation** is an equation for a reaction in solution that shows only those particles that are directly involved in the chemical change.

$$Ag^+(aq) + Cl^-(aq) \longrightarrow AgCl(s)$$

In writing balanced net ionic equations, you must make sure that the ionic charge is balanced. For the previous reaction, the net ionic charge on each side of the equation is zero and is therefore balanced. But consider the skeleton equation for the reaction of lead with silver nitrate.

$$Pb(s) + AgNO_3(aq) \longrightarrow Ag(s) + Pb(NO_3)_2(aq)$$

The nitrate ion is the spectator ion in this reaction. The net ionic equation is as follows:

$$Pb(s) + Ag^+(aq) \longrightarrow Ag(s) + Pb^{2+}(aq) \text{ (unbalanced)}$$

Why is this equation unbalanced? Notice that a single unit of positive charge is on the reactant side of the equation. Two units of positive charge are on the product side. Placing the coefficient 2 in front of $Ag^+(aq)$ balances the charge. A coefficient of 2 in front of Ag(s) rebalances the atoms.

$$Pb(s) + 2Ag^+(aq) \longrightarrow 2Ag(s) + Pb^{2+}(aq) \text{ (balanced)}$$

A net ionic equation shows only those particles involved in the reaction and is balanced with respect to both mass and charge. Of the five types of reactions identified in this chapter, both single- and double-replacement reactions can be written as net ionic equations.

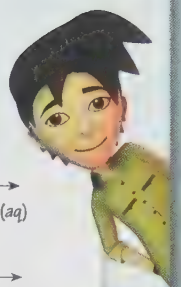
Figure 11.10 Silver Hallide and Medical X-rays Small crystals of a silver halide, usually silver bromide, are embedded in the coating on film used to record medical X-rays. The crystals darken when exposed to X-rays that pass through the human body. Dense parts like bones absorb more X-rays; relatively few rays pass through these parts, which appear as light areas on the developed film. More rays pass through soft tissue, which shows up as darker areas on the developed film. Metals also strongly absorb X-rays.
Identify ***How can you determine from this x-ray whether there is any metal in the foot?***

Differentiated Instruction

LPR LESS PROFICIENT READERS Explain that net ionic equations are a direct and simple way to describe chemical change. Ask four student volunteers to represent two people who go to a dance on a double date and then watch while their partners dance together. Explain that the students watching represent spectator ions and the couple dancing represent the ions that form a precipitate.

L3 ADVANCED STUDENTS Explain that precipitation reactions can occur in the human body under certain conditions. Have students research the precipitation reactions involved in the formation of kidney stones and gall stones, and write complete and net ionic equations for each reaction.

L1 STRUGGLING STUDENTS Discuss with students the steps involved in writing and balancing ionic equations. Help students create a checklist they can refer to when writing balanced ionic equations.



SampleProblem 11.8

Writing and Balancing Net Ionic Equations

Aqueous solutions of iron(III) chloride and potassium hydroxide are mixed. A precipitate of iron(III) hydroxide forms. Identify the spectator ions and write a balanced net ionic equation for the reaction.

1 Analyze **Identify the relevant concepts.** Write the complete ionic equation. Eliminate aqueous ions that appear in both the reactants and products. Then balance the equation with respect to both mass and charge.

2 Solve **Apply concepts to this problem.**

Write the complete ionic equation for the reaction, showing any soluble ionic compounds as individual ions.

$$Fe^{3+}(aq) + 3Cl^-(aq) + 3K^+(aq) + 3OH^-(aq) \longrightarrow Fe(OH)_3(s) + 3K^+(aq) + 3Cl^-(aq)$$

Eliminate aqueous ions that appear in both reactants and products. The spectator ions are K^+ and Cl^-.

$$Fe^{3+}(aq) + \cancel{3Cl^-(aq)} + \cancel{3K^+(aq)} + 3OH^-(aq) \longrightarrow Fe(OH)_3(s) + \cancel{3K^+(aq)} + \cancel{3Cl^-(aq)}$$

Balance the net ionic equation.

$$Fe^{3+}(aq) + 3OH^-(aq) \longrightarrow Fe(OH)_3(s)$$

25. Write the balanced net ionic equation for this reaction.

$$Ca^{2+}(aq) + OH^-(aq) + H^+(aq) + PO_4^{3-}(aq) \longrightarrow Ca^{2+}(aq) + PO_4^{3-}(aq) + H_2O(l)$$

26. Write the complete ionic equation and net ionic equation for the reaction of aqueous calcium hydroxide with phosphoric acid. The products are calcium phosphate and water.

Predicting the Formation of a Precipitate

How can you predict the formation of a precipitate in a double-replacement reaction?

You have seen that mixing solutions of two ionic compounds can sometimes result in the formation of an insoluble salt called a precipitate. Some combinations of solutions produce precipitates, while others do not. Whether or not a precipitate forms depends upon the solubility of the new compounds that form. **By using the general rules for solubility of ionic compounds, you can predict the formation of a precipitate.** These general rules are shown in Table 11.3.

Foundations for Math

SIMPLIFYING EQUATIONS Explain to students that when they simplify a mathematical expression or an equation, they combine like terms and write the answer in simplest form. For example, write the following equation on the board:

$$3x^2 + 4x - 7xy + 2 = 4y + 3x^2 - 7xy$$

Note that crossing out spectator ions from an ionic equation is similar to using inverse operations to solve a mathematical equation. Demonstrate it by crossing out the like terms on the left- and right-hand sides of the equals sign. Note that in the mathematical equation, like terms have the same coefficients, the same variables, and the same mathematical signs in front of them.

In **Sample Problem 11.9**, point out that the spectator ions can be identified by the fact that they are identical in symbol, charge, and coefficient. Remind students that the states of spectator ions will always be aqueous.

EXPLAIN

Sample Practice Problem

Write a balanced net ionic equation for the reaction between sulfuric acid (H_2SO_4) and sodium hydroxide (NaOH). ($H^+(aq) + OH^-(aq) \rightarrow H_2O(l)$)

Answers

READING SUPPORT The spectators at a football game are present at the game, but they don't participate in it.

FIGURE 11.10 Metal and bone both absorb x-rays. You can examine the lighter areas of the x-ray to see if there are shapes other than bones in the image and determine if those shapes resemble metal objects.

25. $OH^-(aq) + H^+(aq)\ H_2O(l)$

26. complete ionic equation: $3Ca^{2+}(aq) + 6OH^-(aq) + 6H^+(aq) + 2PO_4^{3-}(aq) \rightarrow Ca_3(PO_4)_2(s) + 6H_2O(l)$
net ionic equation: same as complete ionic equation

Explain

Predicting the Formation of a Precipitate

USE VISUALS Direct students' attention to Table 11.3. Have students practice reading the table and using the solubility rules to decide whether or not some compounds are soluble. Then, have students use the solubility rules to determine whether the following ionic compounds are soluble or not:

a. $PbCl_2$ *(not)*
b. KOH *(soluble)*
c. NaOH *(soluble)*
d. $Ba(OH)_2$ *(soluble)*
e. Fe_2S_3 *(not)*

APPLY CONCEPTS On the board, write the products only of several double-replacement reactions; challenge students to fill in the reactants. Examples include: → $AgBr(s) + KNO_3(aq)$, → $BaSO_4(s) + 2NaCl(aq)$, → $2KCl(aq) + CaSO_4(s)$. *(KBr(aq) + $AgNO_3$(aq), and $CaCl_2$(aq) + K_2SO_4(aq))* Remind students that in a double-replacement reaction, the positive ions (cations) of one compound trade places with the positive ions of another compound.

CHEMISTRY & YOU Calcium carbonate reacts with carbon dioxide dissolved in water to form soluble calcium hydrogen carbonate. Carbon dioxide then converts calcium hydrogen carbonate back to calcium carbonate, which precipitates and forms the soda straws.

VIRTUAL LAB *Learn more about the solubility rules online.*

Table 11.3

Solubility Rules for Ionic Compounds

Compounds	Solubility	Exceptions
Salts of alkali metals and ammonia	Soluble	Some lithium compounds
Nitrate salts and chlorate salts	Soluble	Few exceptions
Sulfate salts	Soluble	Compounds of Pb, Ag, Hg, Ba, Sr, and Ca
Chloride salts	Soluble	Compounds of Ag and some compounds of Hg and Pb
Carbonates, phosphates, chromates, sulfides, and hydroxides	Most are insoluble	Compounds of the alkali metals and of ammonia

Will a precipitate form when aqueous solutions of $Na_2CO_3(aq)$ and $Ba(NO_3)_2(aq)$ are mixed?

$$2Na^+(aq) + CO_3^{2-}(aq) + Ba^{2+}(aq) + 2NO_3^-(aq) \longrightarrow ?$$

CHEMISTRY & YOU

Q: *How did the soda straws, which are composed of calcium carbonate, get into the cave?*

When these four ions are mixed, the cations could change partners. If they did, the two new compounds that would form are $NaNO_3$ and $BaCO_3$. These are the only new combinations of cation and anion possible. To find out if an exchange will occur, refer to Table 11.3, which gives guidelines for determining whether ion combinations are soluble. Recall that sodium is an alkali metal. Rows 1 and 2 tell you that sodium nitrate will not form a precipitate because alkali metal salts and nitrate salts are soluble. Row 5 indicates that carbonates in general are insoluble. Barium carbonate will precipitate. In this reaction, Na^+ and NO_3^- are spectator ions. The net ionic equation for this reaction is as follows:

$$Ba^{2+}(aq) + CO_3^{2-}(aq) \longrightarrow BaCO_3(s)$$

Figure 11.11 Ions
A precipitate forms when aqueous solutions of sodium sulfate (Na_2SO_4) and barium nitrate ($Ba(NO_3)_2$) are mixed. The net ionic equation for this reaction is as follows:

$Ba^{2+}(aq) + SO_4^{2-}(aq) \longrightarrow BaSO_4(s)$

Apply Concepts ***Which ions are present in the final solution but are not part of the net ionic equation?***

Focus on ELL

4 LANGUAGE PRODUCTION Have students work in groups of four to complete the Small-Scale Lab on page 374. Make sure each group has ELLs of varied language proficiencies so that more proficient students can help less proficient ones. Have students work according to their proficiency level.

BEGINNING: LOW/HIGH Paraphrase each procedure and model it for the students. Allow them to draw pictures or diagrams to describe the reaction in each box.

INTERMEDIATE: LOW/HIGH Allow students to use short phrases and simple sentences to answer questions.

ADVANCED: LOW/HIGH Have these students help students with lower English proficiencies to complete their charts and answer the questions.

SampleProblem 11.9

Writing and Balancing Net Ionic Equations

Aqueous potassium carbonate reacts with aqueous strontium nitrate. Identify the precipitate formed and write the net ionic equation for the reaction.

1 Analyze **Identify the relevant concepts.** Write the reactants. Look at possible new pairings of cation and anion that give an insoluble substance. Eliminate the spectator ions.

2 Solve **Apply concepts to this situation.**

Use the solubility rules in Table 11.3 to identify the precipitate formed.

Write the reactants, showing each as dissociated ions.

$2K^+(aq) + CO_3^{2-}(aq) + Sr^{2+}(aq) + 2NO_3^-(aq) \longrightarrow ?$

Look at possible new pairings of cation and anion that give an insoluble substance.

Of the two possible combinations, KNO_3 is soluble and $SrCO_3$ is insoluble.

Eliminate the spectator ions and write the net ionic equation.

$CO_3^{2-}(aq) + Sr^{2+}(aq) \longrightarrow SrCO_3(s)$

27. Identify the precipitate formed when solutions of these compounds are mixed. Write the net ionic equation.

$NH_4Cl(aq) + Pb(NO_3)_2(aq) \longrightarrow$

28. Write a complete ionic equation and a net ionic equation for the reaction of aqueous solutions of iron(III) nitrate and sodium hydroxide.

11.3 LessonCheck

29. **Review** What is a net ionic equation?

30. **Explain** How can you predict the formation of a precipitate in a double-replacement reaction?

31. **Apply Concepts** Write a balanced net ionic equation for each reaction.

a. $Pb(NO_3)_2(aq) + H_2SO_4(aq) \longrightarrow PbSO_4(s) + HNO_3(aq)$

b. $Pb(C_2H_3O_2)_2(aq) + HCl(aq) \longrightarrow PbCl_2(s) + HC_2H_3O_2(aq)$

c. $Na_3PO_4(aq) + FeCl_3(aq) \longrightarrow NaCl(aq) + FePO_4(s)$

d. $(NH_4)_2S(aq) + Co(NO_3)_2(aq) \longrightarrow CoS(s) + NH_4NO_3(aq)$

32. **Identify** List the precipitate formed when solutions of these ionic compounds are mixed.

a. $H_2SO_4 + BaCl_2 \longrightarrow$

b. $Al_2(SO_4)_3 + NH_4OH \longrightarrow$

c. $AgNO_3 + H_2S \longrightarrow$

d. $CaCl_2 + Pb(NO_3)_2 \longrightarrow$

e. $Ca(NO_3)_2 + Na_2CO_3 \longrightarrow$

33. **Apply Concepts** Hard water contains calcium and magnesium ions. One way to soften water is to add sodium phosphate. Write complete and net ionic equations for the reaction of these two alkaline earth ions with aqueous sodium phosphate.

Lesson Check Answers

29. A net ionic equation shows only those particles involved in the reaction and is balanced with respect to both mass and charge.

30. Use the general rules for solubility of ionic compounds (Table 11.3).

31. **a.** $Pb^{2+}(aq) + SO_4^{2-}(aq) \rightarrow PbSO_4(s)$

b. $Pb^{2+}(aq) + 2Cl^-(aq) \rightarrow PbCl_2(s)$

c. $Fe^{3+}(aq) + PO_4^{3-}(aq) \rightarrow FePO_4(s)$

d. $Co^{2+}(aq) + S^{2-}(aq) \rightarrow CoS(s)$

32. **a.** $BaSO_4(s)$ **b.** $Al(OH)_3(s)$ **c.** $Ag_2S(s)$ **d.** $PbCl_2(s)$ **e.** $CaCO_3(s)$

33. Ca^{2+}, complete: $3Ca^{2+}(aq) + 6Na^+(aq) + 2PO_4^{3-}(aq) \rightarrow 6Na^+(aq) + Ca_3(PO_4)_2(s)$

Ca^{2+}, net: $3Ca^{2+}(aq) + 2PO_4^{3-}(aq) \rightarrow Ca_3(PO_4)_2(s)$

Mg^{2+}, complete: $3Mg^{2+}(aq) + 6Na^+(aq) + 2PO_4^{3-}(aq) \rightarrow 6Na^+(aq) + Mg_3(PO_4)_2(s)$

Mg^{2+}, net: $3Mg^{2+}(aq) + 2PO_4^{3-}(aq) \rightarrow Mg_3(PO_4)_2(s)$

LESSON 11.3

Explain

Sample Practice Problem

Have students write a complete ionic equation and a net ionic equation for the reaction of aqueous solutions of HCl and Na_2S.

(complete: $H^+(aq) + Cl^-(aq) + Na^+(aq) + S^{2-}(aq) \rightarrow H_2S(g) + Na^+(aq) + Cl^-(aq)$; net: $H^+(aq) + S^{2-}(aq) \rightarrow H_2S(g)$)

Evaluate

Informal Assessment

To evaluate students' understanding of complete ionic equations, net ionic equations, and the formation of precipitates, write the reactants in some precipitation reactions on the board. Include at least one example for which no reaction occurs. Have students write complete and net ionic equations for each set of reactants or indicate that no reaction occurs. Then have students complete the 11.3 Lesson Check.

Reteach

Review with students the writing and balancing of complete and net ionic equations and the use of solubility rules to predict the outcome of double-replacement reactions. Stress that it is important to note the physical states of reactants and products in precipitation reactions. Remind students that in a double-replacement reaction, the positive ions (cations) of one compound trade places with the positive ions of another compound.

Answers

FIGURE 11.11 sodium and nitrate

27. $2Cl^-(aq) + Pb^+(aq) \rightarrow PbCl_2(s)$

28. $Fe^{3+}(aq) + 3NO_3^-(aq) + 3Na^+(aq) + 3OH^-(aq) \rightarrow Fe(OH)_3(s) + 3Na^+(aq) + 3NO_3^-(aq)$

$Fe^{3+}(aq) + 3OH^-(aq) \rightarrow Fe(OH)_3(s)$

Explore

OBJECTIVE Students observe, identify, and write balanced equations for precipitation reactions.

PREP TIME 30 minutes

CLASS TIME 40 minutes

ADVANCE PREPARATION

Solution	Preparation
0.05*M* $AgNO_3$	2.1 g in 250 mL
0.2*M* $Pb(NO_3)_2$	16.6 g in 250 mL
0.5*M* $CaCl_2$	13.9 g in 250 mL
1.0*M* Na_2CO_3	26.5 g in 250 mL
0.1*M* Na_3PO_4	9.5 g $Na_3PO_4 \cdot 12H_2O$ in 250 mL
0.5*M* NaOH	20.0 g in 1.0 L
0.2*M* Na_2SO_4	7.1 g in 250 mL
1.0*M* NaCl	14.6 g in 250 mL

DISPOSAL Flush all chemicals down the drain with excess water.

ANALYZE

1. **a.** $Na_2CO_3 + 2AgNO_3 \rightarrow 2NaNO_3 + Ag_2CO_3(s)$
   b. $2Na_3PO_4 + 3Pb(NO_3)_2 \rightarrow 6NaNO_3 + Pb_3(PO_4)_2(s)$
2. Sodium hydroxide and calcium chloride form sodium chloride and solid calcium hydroxide.
3. Mixings d, n, and o do not react.
4. $Na_3PO_4 + 3AgNO_3 \rightarrow 3NaNO_3 + Ag_3PO_4(s)$
   $NaOH + AgNO_3 \rightarrow NaNO_3 + AgOH(s)$
   (actual products: $NaNO_3 + Ag_2O(s) + H_2O$)
   $NaCl + AgNO_3 \rightarrow NaNO_3 + AgCl(s)$
   $Na_2CO_3 + Pb(NO_3)_2 \rightarrow 2NaNO_3 + PbCO_3(s)$
   $2NaOH + Pb(NO_3)_2 \rightarrow 2NaNO_3 + Pb(OH)_2(s)$
   $Na_2SO_4 + Pb(NO_3)_2 \rightarrow 2NaNO_3 + PbSO_4(s)$
   $2NaCl + Pb(NO_3)_2 \rightarrow 2NaNO_3 + PbCl_2(s)$
   $Na_2CO_3 + CaCl_2 \rightarrow 2NaCl + CaCO_3(s)$
   $2Na_3PO_4 + 3CaCl_2 \rightarrow 6NaCl + Ca_3(PO_4)_2(s)$
   $2NaOH + CaCl_2 \rightarrow 2NaCl + Ca(OH)_2(s)$
5. $2Ag^+ + CO_3^{2-} \rightarrow Ag_2CO_3(s)$
   $3Ag^+ + PO_4^{3-} \rightarrow Ag_3PO_4(s)$
   $Ag^+ + OH^- \rightarrow AgOH(s)$
   $Ag^+ + Cl^- \rightarrow AgCl(s)$
   $Pb^{2+} + CO_3^{2-} \rightarrow PbCO_3(s)$
   $3Pb^{2+} + 2PO_4^{3-} \rightarrow Pb_3(PO_4)_2(s)$
   $Pb^{2+} + 2OH^- \rightarrow Pb(OH)_2(s)$
   $Pb^{2+} + SO_4^{2-} \rightarrow PbSO_4(s)$
   $Pb^{2+} + 2Cl^- \rightarrow PbCl_2(s)$
   $Ca^{2+} + CO_3^{2-} \rightarrow CaCO_3(s)$
   $3Ca^{2+} + 2PO_4^{3-} \rightarrow Ca_3(PO_4)_2(s)$
   $Ca^{2+} + 2OH^- \rightarrow Ca(OH)_2(s)$

Small-Scale Lab

Precipitation Reactions: Formation of Solids

Purpose

To observe, identify, and write balanced equations for precipitation reactions

Materials

- pencil
- paper
- ruler
- reaction surface
- chemicals shown in the grid to the right

	$AgNO_3$ (Ag^+)	$Pb(NO_3)_2$ (Pb^{2+})	$CaCl_2$ (Ca^{2+})
Na_2CO_3 (CO_3^{2-})	a	f	k
Na_3PO_4 (PO_4^{3-})	b	g	l
NaOH (OH^-)	c	h	m
Na_2SO_4 (SO_4^{2-})	d	i	n
NaCl (Cl^-)	e	j	o

Procedure

1. Copy the grid on two sheets of paper.
2. Make each square 2 cm on each side.
3. Draw large black Xs on one of the grids.
4. Place a reaction surface over the grid with black Xs and add the chemicals as shown. Use the other grid as a data table to record your observations for each solution.

Analyze

Using your experimental data, record your answers to the following in the space below your data table.

1. **Explain** Translate the following word equations into balanced chemical equations and explain how the equations represent what happens in grid spaces *a* and *g*.
   a. In grid space *a*, sodium carbonate reacts with silver nitrate to produce sodium nitrate and solid silver carbonate.
   b. In grid space *g*, sodium phosphate reacts with lead(II) nitrate to produce sodium nitrate and solid lead(II) phosphate.
2. **Describe** Write a word equation to represent what happens in grid space *m*.
3. **Explain** What happens in grid space *d*? Which other mixings gave similar results? Is it necessary to write an equation when no reaction occurs?
4. **Describe** Write balanced equations for the other precipitation reactions you observed.
5. **Describe** Write balanced net ionic equations for the other precipitation reactions you observed.

You're the Chemist

The following small-scale activities allow you to develop your own procedures and analyze the results.

1. **Explain** Mix a solution of potassium iodide (KI) with silver nitrate. Then mix potassium iodide solution with lead(II) nitrate. Describe your results. Write balanced equations and net ionic equations for each reaction.
2. **Design an Experiment** Table salt is mostly sodium chloride. Design and carry out an experiment to find out if table salt will form a precipitate with either lead(II) nitrate or silver nitrate. Interpret your results.
3. **Design an Experiment** Design and carry out an experiment to show that iodized table salt contains potassium iodide.

YOU'RE THE CHEMIST

1. $KI + AgNO_3 \rightarrow KNO_3 + AgI(s)$
   $Ag^+ + I^- \rightarrow AgI(s)$
   $2KI + Pb(NO_3)_2 \rightarrow 2KNO_3 + PbI_2(s)$
   $Pb^{2+} + 2I^- \rightarrow PbI_2(s)$
2. Add a drop of $Pb(NO_3)_2$ or $AgNO_3$ to a few grains of salt. Look for white crystals.
3. Place a drop of $Pb(NO_3)_2$ on a small pile of dry table salt. Keep part of the pile dry. Look for yellow lead iodide.

11 Study Guide

BIG IDEA REACTIONS

The law of conservation of mass states that mass is neither created nor destroyed. In order to show that mass is conserved during a reaction, a chemical equation must be balanced. The general types of chemical reactions are combination, decomposition, single-replacement, double-replacement, and combustion reactions. Net ionic equations show only those particles involved in the reaction.

11.1 Describing Chemical Reactions

- To write a skeleton equation, write the formulas for the reactants to the left of the yields sign and the formulas for the products to the right.
- After writing the skeleton equation, use coefficients to balance the equation so that it obeys the law of conservation of mass.

- chemical equation (348)
- skeleton equation (348)
- catalyst (348)
- coefficient (350)
- balanced equation (350)

11.2 Types of Chemical Reactions

- The five general types of reactions are combination, decomposition, single-replacement, double-replacement, and combustion.
- The number of elements and/or compounds reacting is a good indicator of possible reaction type and, thus, possible products.
- In a combination reaction, there is always a single product.
- A decomposition reaction involves the breakdown of a single compound into two or more simpler substances.
- In a single-replacement reaction, both the reactants and the products are an element and a compound.
- A double-replacement reaction generally takes place between two ionic compounds in aqueous solution.
- A combustion reaction always involves oxygen as a reactant.

- combination reaction (356)
- decomposition reaction (358)
- single-replacement reaction (360)
- activity series (360)
- double-replacement reaction (362)
- combustion reaction (363)

11.3 Reactions in Aqueous Solution

- A net ionic equation shows only those particles involved in the reaction and is balanced with respect to mass and charge.
- By using the general rules for solubility of ionic compounds, you can predict the formation of a precipitate.

- complete ionic equation (370)
- spectator ion (370)
- net ionic equation (370)

UbD Performance Tasks

IDENTIFYING REACTIONS Provide students with the reactants only of a series of reactions. Have students write balanced equations to complete each reaction and identify the type of reaction. Students should explain the reasoning behind each classification.

CORAL REEFS Explain that limestone is sedimentary rock formed from the exoskeletons of marine corals. Have students research the formation of these exoskeletons and write a report on the chemical processes involved. Reports should include balanced complete and net ionic equations representing the precipitation reactions responsible.

Evaluate

Review and Assessment Materials

WALK-THRU TUTORIALS Each of the Skills Tune-Up problems on the following page has an animated step-by-step tutorial that explains the problem-solving strategy in detail.

PROBLEM SETS Have students practice solving more chemical reaction problems by using the Chapter 11 Online Problem Set.

MATH SKILLS REVIEW Have struggling students practice solving algebraic equations by using the MathXL learning module.

VIRTUAL LABS Have students complete a virtual lab as an in-class or take-home assignment to help reinforce the concepts involved in writing and balancing chemical equations.

Study Tip

Encourage students to use physical models to clarify concepts. For example, for balancing chemical equations or classifying a reaction according to its type, physical models of atoms can aid visual learners. Molecular model kits, foam balls, gumdrops, or modeling clay can be used to represent different types of atoms.

Example and sample practice problems related to balancing chemical equations can be found on the following pages:

LESSON 11.1 Writing a Skeleton Equation—page 349; Balancing a Chemical Equation—pages 352 and 353

LESSON 11.2 Writing Equations for Combination and Decomposition Reactions—page 359; Writing the Equation for Single-Replacement Reactions— page 361; Writing Equations for Double-Replacement Reactions—page 363; Writing Equations for Combustion Reactions—page 365

LESSON 11.3 Writing and Balancing Net Ionic Equations—pages 371 and 373

Skills Tune-Up: Balancing Chemical Equations

Problem	❶ Analyze	❷ Solve
Write the balanced equation for the following reaction: $C_2H_4 + O_2 \longrightarrow$	The reactants are a hydrocarbon and oxygen. The hydrocarbon tells you that the products must be CO_2 and H_2O. The oxygen tells you that this is a combustion reaction.	First write a skeleton equation. $C_2H_4 + O_2 \longrightarrow CO_2 + H_2O$ (unbalanced) Balance the C atoms and the H atoms first. $C_2H_4 + O_2 \longrightarrow 2CO_2 + 2H_2O$ (unbalanced) Balance the O atoms next. $C_2H_4 + 3O_2 \longrightarrow 2CO_2 + 2H_2O$ (balanced)
Write the balanced equation for the following reaction: $Al + Cu(NO_3)_2 \longrightarrow$	$Cu(NO_3)_2$ is an ionic compound, and Al is an element. This is a single-replacement reaction. Check Table 11.2 to be sure a reaction will take place.	First write a skeleton equation. $Al + Cu(NO_3)_2 \longrightarrow Al(NO_3)_3 + Cu$ (unbalanced) Balance the equation. $2Al + 3Cu(NO_3)_2 \longrightarrow 2Al(NO_3)_3 + 3Cu$ (balanced)
Write the balanced equation for the following reaction: $Na(OH)(aq) +$ $Ba(NO_3)_2(aq) \longrightarrow$	Both reactants are ionic compounds, so this is a double-replacement reaction. In a double-replacement reaction, two compounds exchange positive ions. They often produce a gas, a precipitate, or another molecular compound such as water.	Write the reactants, showing each as dissociated free ions. $Na^+(aq) + OH^-(aq) +$ $Ba^{2+}(aq) + 2NO_3^-(aq) \longrightarrow$ Look at the possible new pairings of cation and anion that give an insoluble substance. Of the two possible combinations, $Na(NO)_3$ is soluble and $Ba(OH)_2$ is insoluble. Balance the equation. $2NaOH(aq) + Ba(NO_3)_2(aq) \longrightarrow 2(NaNO)_3(aq) + Ba(OH)_2(s)$ (balanced)

A subscript in a polyatomic ion moves with the ion. So the 3 in NO_3 stays with the ion. But the subscript 2 is there only to balance the charges. It's not part of the ion and doesn't move with it.

Use the solubility rules in Table 11.3 to identify the precipitate formed.

Focus on ELL

5 ASSESS UNDERSTANDING Use a variety of informal assessments to help monitor students' progress in this chapter. Include various types of learning assignments, based on each student's language proficiency.

BEGINNING: LOW/HIGH Have students use diagrams to answer questions or describe reactions.

INTERMEDIATE

LOW Ask students to create a song or poem that demonstrates their knowledge of the five different types of chemical reactions.

HIGH Use the students' participation in the labs to assess their ability to demonstrate understanding.

ADVANCED: LOW/HIGH Include questions from previous lessons as part of assessments so that students can retain information.

11 Assessment

* Solutions appear in Appendix E

Lesson by Lesson

11.1 Describing Chemical Reactions

34. Identify the reactants and products in each chemical reaction.

a. Hydrogen gas and sodium hydroxide are formed when sodium is dropped into water.

b. In photosynthesis, carbon dioxide and water react to form oxygen gas and glucose.

35. Write sentences that completely describe each of the chemical reactions shown in these skeleton equations.

a. $NH_3(g) + O_2(g) \xrightarrow{Pt} NO(g) + H_2O(g)$

b. $H_2SO_4(aq) + BaCl_2(aq) \longrightarrow BaSO_4(s) + HCl(aq)$

c. $N_2O_3(g) + H_2O(l) \longrightarrow HNO_2(aq)$

36. The equation for the formation of water from its elements, $H_2(g) + O_2(g) \longrightarrow H_2O(l)$, can be "balanced" by changing the formula of the product to H_2O_2. Explain why this is incorrect.

***37.** Balance the following equations:

a. $PbO_2(s) \longrightarrow PbO(s) + O_2(g)$

b. $Fe(OH)_3(s) \longrightarrow Fe_2O_3(s) + H_2O(s)$

c. $(NH_4)_2CO_3(s) \longrightarrow NH_3(g) + H_2O(g) + CO_2(g)$

d. $CaCl_2(aq) + H_2SO_4(aq) \longrightarrow CaSO_4(s) + HCl(aq)$

11.2 Types of Chemical Reactions

***38.** Write balanced chemical equations for the following combination reactions:

a. $Mg(s) + O_2(g) \longrightarrow$

b. $P(s) + O_2(g) \longrightarrow$ diphosphorus pentoxide

c. $Ca(s) + S(s) \longrightarrow$

39. Write a balanced chemical equation for each decomposition reaction.

a. $Ag_2O(s) \xrightarrow{\Delta}$

b. ammonium nitrate $\xrightarrow{\Delta}$ dinitrogen monoxide + water

40. Use the activity series of metals to write a balanced chemical equation for each single-replacement reaction.

a. $Au(s) + KNO_3(aq) \longrightarrow$

b. $Zn(s) + AgNO_3(aq) \longrightarrow$

c. $Al(s) + H_2SO_4(aq) \longrightarrow$

41. Write a balanced equation for each of the following double-replacement reactions:

a. $H_2C_2O_4(aq) + KOH(aq) \longrightarrow$

b. $CdBr_2(aq) + Na_2S(aq) \longrightarrow$ (Cadmium sulfide is a precipitate.)

42. Write a balanced equation for the complete combustion of each compound.

a. butene (C_4H_8) **b.** propanal (C_3H_6O)

43. Balance each equation and identify its type.

a. $Hf(s) + N_2(g) \longrightarrow Hf_3N_4(s)$

b. $Mg(s) + H_2SO_4(aq) \longrightarrow MgSO_4(aq) + H_2(g)$

c. $C_2H_6(g) + O_2(g) \longrightarrow CO_2(g) + H_2O(g)$

d. $Pb(NO_3)_2(aq) + NaI(aq) \longrightarrow PbI_2(s) + NaNO_3(aq)$

44. What is a distinguishing feature of every decomposition reaction?

11.3 Reactions in Aqueous Solution

45. What is a spectator ion?

***46.** Write a balanced net ionic equation for the following reactions:

a. $HCl(aq) + Ca(OH)_2(aq) \longrightarrow$

b. $AgNO_3(aq) + AlCl_3(aq) \longrightarrow$ (Silver chloride is a precipitate.)

47. Complete each equation and then write a net ionic equation.

a. $Al(s) + H_2SO_4(aq) \longrightarrow$

b. $HCl(aq) + Ba(OH)_2(aq) \longrightarrow$

c. $Au(s) + HCl(aq) \longrightarrow$

Understand Concepts

48. Write a balanced chemical equation for each reaction. Use the necessary symbols from Table 11.1 to describe the reaction completely.

a. Bubbling chlorine gas through a solution of potassium iodide gives elemental iodine and a solution of potassium chloride.

b. Bubbles of hydrogen gas and aqueous iron(III) chloride are produced when metallic iron is dropped into hydrochloric acid.

c. Solid tetraphosphorus decaoxide reacts with water to produce phosphoric acid.

Evaluate

Answers

LESSON 11.1

34. **a.** reactants: sodium and water; products: hydrogen and sodium hydroxide

b. reactants: carbon dioxide and water; products: oxygen and glucose

35. **a.** Gaseous ammonia and oxygen react in the presence of a platinum catalyst to produce nitrogen monoxide gas and water vapor.

b. Aqueous solutions of sulfuric acid and barium chloride are mixed to produce a precipitate of barium sulfate and aqueous hydrochloric acid.

c. The gas dinitrogen trioxide reacts with water to produce an aqueous solution of nitrous acid.

36. A formula is a unique identifier of a substance. A different formula would indicate a different substance, not the one that is taking part in the reaction you are trying to balance.

37. **a.** $2PbO_2(s) \rightarrow 2PbO(s) + O_2(g)$

b. $2Fe(OH)_3(s) \rightarrow Fe_2O_3(s) + 3H_2O(l)$

c. $(NH_4)_2CO_3(s) \rightarrow 2NH_3(g) + H_2O(g) + CO_2(g)$

d. $CaCl_2(aq) + H_2SO_4(aq) \rightarrow CaSO_4(s) + 2HCl(aq)$

c. $4Na + O_2 \rightarrow 2Na_2O$

50. **a.** $ZnS(aq) + H_2SO_4(aq) \rightarrow H_2S(g) + ZnSO_4(aq)$
b. $NaOH(aq) + HNO_3(aq) \rightarrow H_2O(l) + NaNO_3(aq)$
c. $2KF(aq) + Ca(NO_3)_2(aq) \rightarrow CaF_2(s) + 2KNO_3(aq)$

51. **a.** $Na_2O(s) + H_2O(l) \rightarrow 2NaOH(aq)$
b. $H_2(g) + Br_2(g) \rightarrow 2HBr(g)$
c. $Cl_2O_7(l) + H_2O(l) \rightarrow 2HClO_4(aq)$

52. **a.** $Fe(s) + H_2SO_4(aq) \rightarrow FeSO_4(aq) + H_2(g)$
b. no reaction
c. $Br_2(l) + BaI_2(aq) \rightarrow BaBr_2(aq) + I_2(aq)$

53. **a.** tube A
b. $2Na(s) + 2H_2O(l) \rightarrow 2NaOH(aq) + H_2(g)$
single-replacement

54. **a.** $2C_8H_{18} + 25O_2 \rightarrow 16CO_2 + 18H_2O$
b. $C_6H_{12}O_6 + 6O_2 \rightarrow 6CO_2 + 6H_2O$
c. $HC_2H_3O_2 + 2O_2 \rightarrow 2CO_2 + 2H_2O$

55. **a.** $2Al_2O_3 \xrightarrow{\text{energy}} 4Al + 3O_2$
b. $Sn(OH)_4 \xrightarrow{\Delta} SnO_2 + 2H_2O$
c. $Ag_2CO_3 \xrightarrow{\Delta} Ag_2O + CO_2$

56. **a.** $H^+(aq) + OH^-(aq) \rightarrow H_2O(l)$
b. $S^{2-}(aq) + 2H^+(aq) \rightarrow H_2S(g)$
c. $3OH^-(aq) + Fe^{3+}(aq) \rightarrow Fe(OH)_3(s)$

57. **a.** $CdS(s)$
b. $Na^+(aq)$ and $NO_3^-(aq)$
c. $Cd^{2+}(aq) + S^{2-}(aq) \rightarrow CdS(s)$

THINK CRITICALLY

58. **a.** (1) combination
(2) single-replacement
(3) combustion
(4) double-replacement
b. (1) $2Al(s) + 3Br_2(l) \rightarrow 2AlBr_3(s)$
(2) $Cu(s) + 2AgNO_3(aq) \rightarrow Cu(NO_3)_2(aq) + 2Ag(s)$
(3) $C_3H_8(g) + 5O_2(g) \rightarrow 3CO_2(g) + 4H_2O(g)$
(4) $Pb(NO_3)_2(aq) + 2KI(aq) \rightarrow PbI_2(s) + 2KNO_3(aq)$

49. Each equation is incorrect. Find the errors, then rewrite and balance each equation.
a. $Cl_2 + NaI \longrightarrow NaCl_2 + I$
b. $NH_3 \longrightarrow N + H_3$
c. $Na + O_2 \longrightarrow NaO_2$

50. Write balanced chemical equations for these double-replacement reactions that occur in aqueous solution.
a. Zinc sulfide is added to sulfuric acid.
b. Sodium hydroxide reacts with nitric acid.
c. Solutions of potassium fluoride and calcium nitrate are mixed.

***51.** Write a balanced chemical equation for each combination reaction.
a. sodium oxide + water
b. hydrogen + bromine
c. dichlorine heptoxide + water

52. Write a balanced chemical equation for each single-replacement reaction that takes place in aqueous solution. Write "no reaction" if a reaction does not occur.
a. Steel wool (iron) is placed in sulfuric acid.
b. Mercury is poured into an aqueous solution of zinc nitrate.
c. Bromine reacts with aqueous barium iodide.

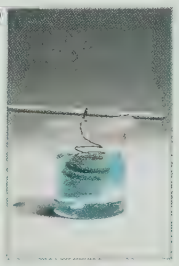
***53.** Pieces of sodium and magnesium are dropped into separate water-filled test tubes (A and B). There is vigorous bubbling in Tube A but not in Tube B.
a. Which tube contains the sodium metal?
b. Write an equation for the reaction in the tube containing the sodium metal. What type of reaction is occurring in this tube?

54. Write a balanced equation for the complete combustion of each compound. Assume that the products are carbon dioxide and water.
a. octane (C_8H_{18})
b. glucose ($C_6H_{12}O_6$)
c. ethanoic acid ($HC_2H_3O_2$)

55. Write balanced chemical equations for these decomposition reactions.
a. Aluminum is obtained from aluminum oxide with the addition of a large amount of electrical energy.
b. Heating tin(IV) hydroxide gives tin(IV) oxide and water.
c. Silver carbonate decomposes into silver oxide and carbon dioxide when it is heated.

56. Write a balanced net ionic equation for each reaction. The product that is not ionized is given.
a. $H_2C_2O_4 + KOH \longrightarrow [H_2O]$
b. $Na_2S + HCl \longrightarrow [H_2S]$
c. $NaOH + Fe(NO_3)_3 \longrightarrow [Fe(OH_3)]$

***57.** A yellow precipitate formed when aqueous solutions of sodium sulfide and cadmium nitrate were mixed in a beaker.
a. Write the formula of the yellow precipitate.
b. Identify the spectator ions in the solution.
c. Write the net ionic equation for the reaction.



Think Critically

58. **Interpret Photos** The photos show various types of reactions.

(1)

(2)

(3)

(4)

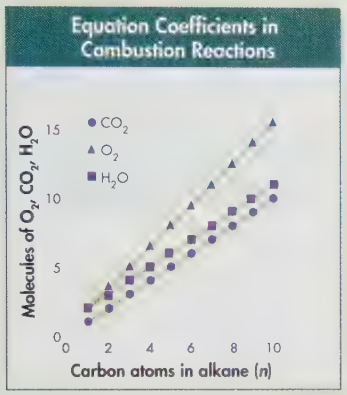
(1) Aluminum reacting with bromine

(2) The reaction of copper with aqueous silver nitrate

(3) Propane (C_3H_8) reacting with oxygen

(4) The reaction of lead(II) nitrate with potassium iodide

a. Identify each type of reaction.
b. Write the equation for each type of reaction.



59. Write a balanced chemical equation for each reaction. Classify each by type.
   a. Sodium iodide reacts with phosphoric acid.
   b. Potassium oxide reacts with water.
   c. Heating sulfuric acid produces water, oxygen, and sulfur dioxide.
   d. Aluminum reacts with sulfuric acid.
   e. Pentane (C_5H_{12}) reacts with oxygen.

*60. When pale yellow chlorine gas is bubbled through a clear, colorless solution of sodium iodide, the solution turns brown.
   a. What type of reaction is taking place?
   b. Write the net ionic equation.

Enrichment

61. **Interpret Graphs** Alkanes are hydrocarbon molecules that have the general formula C_nH_{2n+2}. The graph shows the number of oxygen, carbon dioxide, and water molecules needed to balance the equations for the complete combustion of every alkane having from one to ten carbon atoms.

C_nH_{2n+2} + ___ O_2 ⟶ ___ CO_2 + ___ H_2O

   a. Use the graph to write balanced equations for the combustion of C_5H_{12} and C_9H_{20}.
   b. Extrapolate the graph and write balanced equations for the combustion of $C_{12}H_{26}$ and $C_{17}H_{36}$.
   c. The coefficient for O_2 in the general equation is as follows:

$$n + \frac{n+1}{2}$$

What are the coefficients for CO_2 and H_2O?

*62. **Apply Concepts** Fill in the missing reactant, and then balance each equation.
   a. $K(s)$ + ___ ⟶ $KOH(aq) + H_2(g)$
   b. $C_2H_5OH(l)$ + ___ ⟶ $CO_2(g) + H_2O(g)$
   c. $Bi(NO_3)_3(aq)$ + ___ ⟶ $Bi_2S_3(s) + HNO_3(aq)$
   d. $Al(s)$ + ___ ⟶ $AlBr_3(s)$

Write About Science

63. **Apply Concepts** Research organisms such as fireflies and jellyfish that use bioluminescence, including information on the discovery of green fluorescent protein (GFP). In a pamphlet or poster, explain how bioluminescence works and how each organism uses it.

64. **Observe** Make a list of five chemical reactions that happen in your kitchen. Describe and name each reaction on your list.

*65. **Relate Cause and Effect** Why is smoking not permitted near an oxygen source? What would happen if a match were struck in a room filled with oxygen?

CHEMYSTERY

Order in the Lab

Chemicals should not be stored in alphabetical order because some chemicals that will react if mixed could end up next to each other. For example, acids should not be stored near cyanides, sulfides and other chemicals that produce toxic gases when combined. Acids should also not be stored near bases or active metals. Reactions between acids and bases produce heat. Acids and active metals react to produce gases and heat. Acids and flammables should have separate, dedicated storage areas.

66. Connect to the **BIG**IDEA Should sulfuric acid be stored next to sodium hydroxide? Explain your answer. If they should not be stored next to each other, write a balanced chemical equation to support your answer.

ASSESSMENT

CHEMYSTERY **APPLY CONCEPTS** After students have read through the CHEMystery, call on volunteers to write chemical equations for reactions involving the chemicals that Maria rearranged. **Ask** What gaseous product would form by reacting sulfuric acid with sodium cyanide? *(hydrogen cyanide, HCN)* **Ask** What gaseous product would form from the reaction of sulfuric acid and sodium sulfide? *(hydrogen sulfide, H_2S)* Explain that both HCN and H_2S are gases that can be lethal if inhaled. Because sulfuric acid is a liquid, a very serious situation would have occurred in the lab if a spill occurred while it was stored next to either Na_2S or NaCN.

CHEMYSTERY ANSWERS

66. **BIG**IDEA No; NaOH is a base, and bases should not be stored next to acids because reactions between these two classes of chemicals generate heat.
$H_2SO_4(aq) + 2NaOH(s) \rightarrow Na_2SO_4(aq) + 2H_2O(l)$

Answers

59. a. $3NaI + H_3PO_4 \rightarrow 3HI + Na_3PO_4$; double-replacement
   b. $K_2O + H_2O \rightarrow 2KOH$; combination
   c. $2H_2SO_4 \xrightarrow{\Delta} 2H_2O + O_2 + 2SO_2$; decomposition
   d. $2Al + 3H_2SO_4 \rightarrow 3H_2 + Al_2(SO_4)_3$; single-replacement
   e. $C_5H_{12} + 8O_2 \rightarrow 5CO_2 + 6H_2O$; combustion

60. a. single-replacement
   b. $Cl_2(g) + 2I^-(aq) \rightarrow I_2(aq) + 2Cl^-(aq)$

ENRICHMENT

61. a. $C_5H_{12} + 8O_2 \rightarrow 5CO_2 + 6H_2O$
$C_9H_{20} + 14O_2 \rightarrow 9CO_2 + 10H_2O$
   b. $2C_{12}H_{26} + 37O_2 \rightarrow 24CO_2 + 26H_2O$
$C_{17}H_{36} + 26O_2 \rightarrow 17CO_2 + 18H_2O$
   c. $n = CO_2$; $(n + 1) = H_2O$

62. a. $2K(s) + 2H_2O(l) \rightarrow 2KOH(aq) + H_2(g)$
   b. $C_2H_5OH(l) + 3O_2(g) \rightarrow 2CO_2(g) + 3H_2O(g)$
   c. $2Bi(NO_3)_3(aq) + 3H_2S(g) \rightarrow Bi_2S_3(s) + 6HNO_3(aq)$
   d. $2Al(s) + 3Br_2(l) \rightarrow 2AlBr_3(s)$

WRITE ABOUT SCIENCE

63. Answers will vary, but should indicate an understanding that bioluminescence is a combination reaction that requires a catalyst, and produces an oxidized protein and light.

64. Answers will vary, but should include examples and descriptions of combination, decomposition, single-replacement, double-replacement, and combustion reactions.

65. Answers will vary, but should indicate an understanding that as the oxygen concentration in a combustion reaction increases, the more rapidly the reaction will proceed and the more likely combustion be complete. A fire in an oxygen-filled room will spread much more rapidly and cause significantly more damage than in a room with the concentration of oxygen found in air.

Cumulative Review

67. **a.** water
b. water vapor in the air
c. physical change

68. Element: gold; compounds: sodium chloride, ice with water; homogeneous mixtures, salt water, air; heterogeneous mixture: salt and sand; substance: sodium chloride, gold, water with ice

69. 36.6 kg

70. 22 protons, 28 neutrons, and 22 electrons

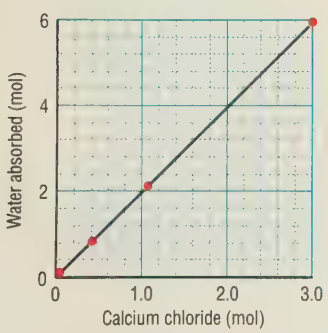
71. **a.** $1s^2 2s^2 2p^6 3s^2 3p^6 4s^2 3d^{10} 4p^6$
b. $1s^2 2s^2 2p^6 3s^2 3p^6$
c. $1s^2 2s^2 2p^6 3s^2 3p^6 3d^{10}$
d. $1s^2 2s^2 2p^6 3s^2 3p^6 3d^{10}$

72. Electronegativity is the tendency for an atom to attract bonded electrons to itself. Electronegativity values increase from left to right in a period.

73. **a.** incorrect; KBr
b. correct
c. incorrect; Ca_3N_2
d. correct

74. **a.** K_2CrO_4
b. $NaHSO_3$
c. permanganic acid
d. potassium oxalate

75. **a.** 2.41 mol
b. 6.91×10^{-2} mol
c. 0.934 mol
d. 7.09 mol



76. **a.** compound 1: $FeSO_4$, compound 2: $FeSO_3$
b. $FeSO_4$, iron(II) sulfate; $FeSO_3$, iron(III) sulfite

77. $C_8H_{10}O_2N_4$

78. **a.**

$CaCl_2$ (mol)	H_2O (mol)
a. 0.156	e. 0.312
b. 0.439	f. 0.878
c. 1.12	g. 2.24
d. 3.03	h. 6.06

b.

c. Two molecules of water.

Cumulative Review

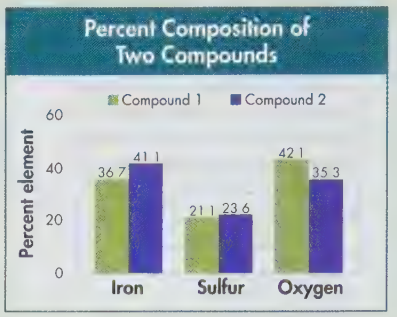
67. When you take a glass of cold liquid outside on a warm, humid day, drops of liquid soon form on the outside of the glass.
a. What is the liquid?
b. Where did the liquid come from?
c. Did a chemical or physical change occur?

68. Classify each of the following as an element, a compound, a homogeneous mixture, a heterogeneous mixture, or a substance. Some may fit in more than one category.
a. salt water
b. sodium chloride
c. air
d. salt and sand
e. gold
f. water with ice

69. A block of ice measures 25.0 cm × 42.0 cm × 38.0 cm. What is the mass of the ice in kilograms? The density of ice is 0.917 g/cm^3.

***70.** List the number of protons, neutrons, and electrons in this isotope of titanium: $^{50}_{22}Ti$.

71. Write electron configurations for the following ions.
a. Sr^{2+} **b.** S^{2-} **c.** Ga^{3+} **d.** Cu^{+}



72. Explain what is meant by *electronegativity*. How do electronegativity values change across a row of representative elements?

73. Are any of the following formulas for ionic compounds incorrect? If so, write the correct formulas.
a. K_2Br **b.** Na_2S **c.** CaN_2 **d.** Al_2O_3

***74.** Give the name or formula for the following compounds:
a. potassium chromate
b. sodium hydrogen sulfite
c. $HMnO_4$
d. $K_2C_2O_4$

75. Calculate the number of moles in each substance.
a. 54.0 L of nitrogen dioxide (at STP)
b. 1.68 g of magnesium ions
c. 69.6 g of sodium hypochlorite
d. 4.27×10^{24} molecules of carbon monoxide

76. The graph shows the percent composition of two different compounds formed by the elements iron, oxygen, and sulfur.

a. Using the data on the graphs, calculate the empirical formula of each compound.
b. Name each compound.

***77.** Many coffees and colas contain the stimulant caffeine. The percent composition of caffeine is 49.5% C, 5.20% H, 16.5% O, and 28.9% N. What is the molecular formula of caffeine if its molar mass is 194.1 g/mol?

78. Calcium chloride ($CaCl_2$) is a white solid used as a drying agent. The maximum amount of water absorbed by different quantities of $CaCl_2$ is given in the table below.

$CaCl_2$ (g)	$CaCl_2$ (mol)	H_2O (g)	H_2O (mol)
17.3	a._____	5.62	e._____
48.8	b._____	15.8	f._____
124	c._____	40.3	g._____
337	d._____	109	h._____

a. Complete the table.
b. Plot the moles of water absorbed (y-axis) versus the moles of $CaCl_2$.
c. Based on your graph, how many molecules of water does each formula unit of $CaCl_2$ absorb?

Standardized Test Prep for Indiana

Standards: C.4.1, C.4.2, C.4.5

Select the choice that best answers each question or completes each statement.

1. When the equation $Fe_2O_3 + H_2 \longrightarrow Fe + H_2O$ is balanced using whole-number coefficients, what is the coefficient of H_2?
   (A) 6 **(B)** 3 **(C)** 2 **(D)** 1

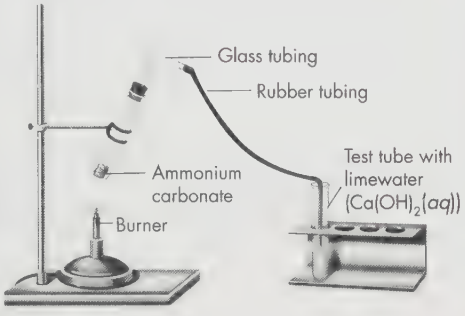
2. Identify the spectator ion in this reaction.
   $Ba(OH)_2(aq) + H_2SO_4(aq) \longrightarrow BaSO_4(s) + H_2O(l)$
   (A) Ba^{2+} **(B)** SO_4^{2-} **(C)** OH^- **(D)** H^+ **(E)** There is no spectator ion.

3. Magnesium ribbon reacts with an aqueous solution of copper(II) chloride in a single-replacement reaction. Which are the products of the balanced net ionic equation for the reaction?
   (A) $Mg^{2+}(aq) + 2Cl^-(aq) + Cu(s)$
   (B) $Mg^+(aq) + Cl^-(aq) + Cu^+(aq)$
   (C) $Mg^{2+}(aq) + Cu(s)$
   (D) $Cu(s) + 2Cl^-(aq)$

Use the following description and data table to answer Questions 4–6.

Dropper bottles labeled P, Q, and R contain one of three aqueous solutions: potassium carbonate, K_2CO_3; hydrochloric acid, HCl; and calcium nitrate, $Ca(NO_3)_2$. The table shows what happens when pairs of solutions are mixed.

Solution	P	Q	R
P	—	Precipitate	No reaction
Q	Precipitate	—	Gas forms.
R	No reaction	Gas forms.	—



4. Identify the contents of each dropper bottle.
5. Write the net ionic equation for the formation of the precipitate.
6. Write the complete ionic equation for the formation of the gas.

7. Which are the expected products of the decomposition reaction of potassium oxide, K_2O?
   (A) $K^+(s)$ and $O^{2-}(g)$
   (B) $K^+(s)$ and $O_2(g)$
   (C) $K(s)$ and $O_2^{2-}(g)$
   (D) $K(s)$ and $O_2(g)$

Tips for Success

Interpreting Diagrams Before you answer questions about a diagram, study the diagram carefully. Read all captions and labels. Look at all the information in the diagram and think about how it all interrelates.

Use the diagram to answer Questions 8–11.

8. When ammonium carbonate is heated, water, ammonia, and carbon dioxide are produced. What type of chemical reaction is occurring?
9. Write formulas for the reaction products.
10. Write a balanced equation for the reaction. Include states for reactants and products.
11. Limewater is used to test for the presence of carbon dioxide gas. The products of the reaction of $Ca(OH)_2$ with CO_2 are calcium carbonate and water. Write a balanced equation for the reaction.

Materials List

For the Student

Small-Scale Lab, p 399
- baking soda
- 3 plastic cups
- soda straw
- balance
- pipets of HCl, NaOH, and thymol blue
- pH sensor (optional)

Quick Lab, p 404
- graduated cylinder
- balance
- 3 250-mL Erlenmeyer flasks
- 3 rubber balloons
- 4.2 g magnesium ribbon
- 300 mL 1.0M hydrochloric acid

For the Teacher

Teacher Demo, p 387
- 2.5–3.5-cm strip of magnesium
- 50 mL 1M HCl
- 100-mL beaker
- baking soda

Teacher Demo, p 392
- 0.1M KI
- 0.1M $Pb(NO_3)_2$
- 250-mL beakers

Class Activity, p 396
- 8 index cards
- 1 colored index card
- paper punch
- 2 brass paper fasteners

Teacher Demo, p 401
- 15 plastic bottles
- 30 plastic caps to fit the bottles
- 6 containers to hold 5 caps each

Teacher Demo, p 403
- 20 metal paper clips (symbol M)
- 20 same-colored vinyl-coated paper clips (symbol C)
- plastic sandwich bag

Class Activity, p 405
- 3 foam cups
- a thermometer
- 100 mL of 1.0M HCl
- approximately 200 mL of 1.0M NaOH

Online Teacher's Edition
12.2 Virtual Chem Lab 28: Analysis of Baking Soda
Analysis of Baking Soda

What's Online

CHEM TUTOR Students access guided step-by-step tutorials for solving various stoichiometry problems. Students can practice key problem-solving skills in an online problem set.

MATH HELP Identify the students that struggle with math by assigning an online math skills diagnostic test. These students can then improve and practice math skills using the MathXL tutorial system.

VIRTUAL LAB Students go into a virtual lab tour in which stoichiometry is studied in a simulated laboratory environment.

KINETIC ART Students watch animations of selected figures from the chapter followed by questions to check for understanding.

CONCEPTS IN ACTION Students watch an overview of a key chapter concept using real-world contexts and concrete examples and analogies. Each activity includes an interactive animation followed by analysis questions.

12 Stoichiometry

INSIDE:

- **12.1** The Arithmetic of Equations
- **12.2** Chemical Calculations
- **12.3** Limiting Reagent and Percent Yield

PearsonChem.com

Like a chemical equation, a recipe tells you the amount of each ingredient (your reactants) needed to make your product, in this case, bread.

382

IN ACADEMIC STANDARDS for SCIENCE

Nature of Science

- Use analogies and models (mathematical and physical) to simplify and represent systems that are difficult to understand or directly experience due to their size, time scale, or complexity, and recognize the limitations of analogies and models.

Standard 4: Reactions and Stoichiometry

C.4.3 Use the mole concept to determine moles and number of atoms or molecules in samples of elements and compounds, given mass of the sample.

C.4.4 Using a balanced chemical equation, calculate the amounts of reactants needed or products made in a chemical reaction that goes to completion.

Also covered C.1.6, C.4.2, C.5.3.

Focus on ELL

1 CONTENT AND LANGUAGE Present the chapter title by writing *stoichiometry* on the board and the phonetic spelling, toy kee AHM uh tree. Model pronunciation and have students repeat after you. Direct students' attention to the photograph. Ask students what a recipe has to do with stoichiometry. Help students see that a recipe and stoichiometry both measure reactants and products and predict results.

BEGINNING LOW Have students write the word *stoichiometry* on one side of a note card, and on the other side, have them copy the phonetic spelling of it.

HIGH Have students determine the quantities of ingredients they would use to make a ham and cheese sandwich and write an equation.

INTERMEDIATE: LOW/HIGH Paraphrase the Essential Questions. Summarize the CHEMystery story by writing the main idea of the story.

ADVANCED: LOW/HIGH Develop a list of words that have the suffix *-metry*, which means "to measure." Present the words to the class, along with their meanings.

BIG IDEAS

- THE MOLE
- REACTIONS

Essential Questions:

1. *How are balanced chemical equations used in stoichiometric calculations?*
2. *How can you calculate amounts of reactants and products in a chemical reaction?*

CHEMYSTERY

Cookie Crumbles

For the school bake sale, Jack wanted to make cookies to sell. He looked in cookbooks to find a good recipe. The recipe he chose called for specific amounts of butter, flour, sugar, eggs, vanilla, and baking soda. Jack wanted to make sure that his cookies were delicious and sweet. He didn't think there was enough sugar in the recipe, so he added twice as much sugar as the recipe called for.

Jack mixed the ingredients, put balls of the dough on a cookie sheet, and placed them in the oven to bake. When the bake time was up, Jack was very disappointed in his cookies. Instead of sweet, delicious cookies, his cookies were brown, hard, and crumbly. What happened? He checked the oven temperature and the amount of time that the cookies were in the oven. The time and temperature matched the directions in the recipe. Why didn't Jack's cookies turn out as he expected?

▶ Connect to the BIG IDEA As you read about quantifying chemical reactions, think about what could have happened to Jack's cookies.

INDIANA'S ACADEMIC STANDARDS FOR SCIENCE

Properties and States of Matter C.1.6; **Reactions and Stoichiometry** C.4.2, C.4.3, C.4.4; **Behavior of Gases** C.5.3. See lessons for details.

Introduce the Chapter

IDENTIFY PRECONCEPTIONS Students often enter into the study of stoichiometry with preconceptions. Use the activity to show them that all reactants may not be used up during a reaction.

Activity *You'll need to get a bowl and place in it 5 chocolate pieces, 8 graham crackers, and 9 marshmallows.* **Ask** What's the ratio of reactants if you need one chocolate piece, two graham crackers and two mini-marshmallows to make one s'more? *(1:2:2 yields 1.)*

Have students predict the number of s'mores you will be able to make with your reactants. *(Answers will vary.)* Then, make as many s'mores as you can with the reactants that you have. **Ask** How many s'mores did I make? *(four)* **Ask** Did I use up all my reactants? *(no)* **Ask** What prevented me from being able to make more s'mores? *(I ran out of graham crackers.)*

UbD Understanding by Design

Students are building toward measuring the efficiency of a chemical reaction by using the relationships of the mole and quantifying matter.

PERFORMANCE GOALS At the end of Chapter 12, students will be able to answer the essential questions by applying their knowledge of stoichiometry. Students will also be able to calculate and compare the theoretical yield and the actual yield of a chemical reaction.

ESSENTIAL QUESTIONS Read the essential questions aloud. **Ask** What is conserved in a balanced chemical equation? *(atoms, molecules, moles, mass, volume)* **Ask** What information do you need to have before you can calculate the amount of a reactant or product? *(the number of moles of the substance and the number of grams or liters of the substance in each mole)*

BIG IDEA Use the chapter opener photo to help students connect with the Big Idea of the relationship of balanced equations and stoichiometric equations. Invite students to share their experiences with recipes and ingredients, and the results. **Ask** How would you adjust the recipe to double it? Guide students to an understanding of the importance of maintaining the correct ratios of ingredients when adjusting a recipe.

CHEMYSTERY Have students read over the CHEMystery. Connect the CHEMystery to the Big Idea by explaining that the amounts of reactants and products of a reaction can be predicted using a balanced chemical equation. Mole ratios of a balanced chemical equation can be used to relate the moles of reactant to the moles of product, and mass ratios can be used to relate the mass of reactant to the mass of product. Ask students to predict what happens to the cookies as a result of the additional sugar. As a hint, tell students that when they adjust a recipe, the ratios of the ingredients must be the same in order to achieve the desired product.

LESSON 12.1

Key Objectives

12.1.1 DESCRIBE how chemists use balanced chemical equations.

12.1.2 DESCRIBE the quantities you can use to interpret a balanced chemical equation.

12.1.3 IDENTIFY the quantities that are always conserved in chemical reactions.

Additional Resources

- Reading and Study Workbook, Lesson 12.1
- Probeware Laboratory Manual, Lab 19
- Teaching Resources, Lesson 12.1 Review

PearsonChem.com

Engage

CHEMISTRY & YOU Have students study the photograph and read the text that opens the lesson. **Ask** How many wheels would be needed to make 200 bikes? *(twice as many frames, or 400)* **Ask** How did you calculate the number of frames? *(multiplied the number needed for 200 bikes by two)*

Activate Prior Knowledge

Tell students that the word *stoichiometry* comes from the Greek words *stoicheion,* meaning "element," and *metron*, meaning "measure." Draw a two-column chart on the board, with *Reactants* on one side and *Products* on the other. Invite students to brainstorm a list of measurements that a chemist might use in relation to products and reactants, such as mass and moles. Ask students to compare the list to measurements studied in chemical reactions that relate to reactants and products.

IN ACADEMIC STANDARDS for SCIENCE

- Apply standard techniques in laboratory investigations to measure physical quantities in appropriate units and convert known quantities to other units as necessary.
- Use analogies and models (mathematical and physical) to simplify and represent systems that are difficult to understand or directly experience due to their size, time scale, or complexity, and recognize the limitations of analogies and models.

C.4.2 Balance chemical equations using the law of conservation of mass and use them to describe chemical reactions.

Also covered C.1.6, C.4.3

12.1 The Arithmetic of Equations

C.1.6 Conservation of mass: chemical changes; **C.4.2** Balance chemical equations; **C.4.3** The mole concept

CHEMISTRY & YOU

Q: *How do you figure out how much starting material you need to make a finished product?* Whenever you make something, you need to have the ingredients or the parts that make up the desired product. When making bikes, you need parts such as wheels, handlebars, pedals, and frames. If a factory needs to make 200 bikes, then the workers would need to calculate how many of each part they need to produce the 200 bikes. In this lesson, you will learn about how chemists determine how much of each reactant is needed to make a certain amount of product.

Key Questions

How do chemists use balanced chemical equations?

In terms of what quantities can you interpret a balanced chemical equation?

Vocabulary

- stoichiometry

Using Equations

How do chemists use balanced chemical equations?

One example of something that you might make is food. When you make cookies, for instance, you probably use a recipe. A cookie recipe tells you the precise amounts of ingredients to mix to make a certain number of cookies. If you need a larger number of cookies than the recipe provides for, you can double or triple the amounts of all the ingredients. In a way, a cookie recipe provides the same kind of information that a balanced chemical equation provides. In a cookie recipe, you can think of the ingredients as the reactants and the cookies as the products.

Everyday Equations The making of tricycles, like bikes and cookies, is a job that requires quantitative information to create the final product. Let's say you are in charge of manufacturing for the Travel Time Tricycle Company. The business plan for Travel Time requires the production of 640 custom-made tricycles each week. One of your responsibilities is to make sure there are enough parts available at the start of each workweek to make these tricycles. How can you determine the number of parts you need per week?

To simplify this discussion, assume that the major components of the tricycle are the frame (F), the seat (S), the wheels (W), the handlebars (H), and the pedals (P)—in other words, the reactants. The figure below illustrates how an equation can represent the manufacturing of a single tricycle.

F + S + 3W + H + 2P ⟶ FSW_3HP_2

Focus on ELL

1 CONTENT AND LANGUAGE Begin the lesson by reviewing the meaning of the words *interpret, balanced, conservation,* and *arithmetic.* Review the key symbols used in chemical equations as well as the rules for writing and balancing a chemical equation.

2 FRONTLOAD THE LESSON Have students bring in their favorite recipes from their native countries, and guide students to understand how their recipes are similar to balanced chemical equations.

3 COMPREHENSIBLE INPUT Have students model Figure 12.2 using colored paper clips. Use one color to represent a nitrogen atom and one color to represent a hydrogen atom. Explain that 2 links of the same color represent either a nitrogen molecule or a hydrogen molecule.

The finished tricycle, your product, has a "formula" of FSW_3HP_2. The balanced equation for making a single tricycle is

$$F + S + 3W + H + 2P \longrightarrow FSW_3HP_2$$

This balanced equation is a "recipe" to make a single tricycle: Making a tricycle requires assembling one frame, one seat, three wheels, one handlebar, and two pedals. Now look at Sample Problem 12.1. It shows you how to use the balanced equation to calculate the number of parts needed to manufacture a given number of tricycles.

SampleProblem 12.1

Using a Balanced Equation as a Recipe

In a five-day workweek, Travel Time is scheduled to make 640 tricycles. How many wheels should be in the plant on Monday morning to make these tricycles?

1 Analyze **List the knowns and the unknown.**
Use the balanced equation to identify a conversion factor that will allow you to calculate the unknown. The conversion you need to make is from tricycles (FSW_3HP_2) to wheels (W).

KNOWNS

number of tricycles = 640 tricycles = 640 FSW_3HP_2

$F + S + 3W + H + 2P \longrightarrow FSW_3HP_2$

UNKNOWN

number of wheels = ? W

2 Calculate **Solve for the unknown.**

Identify a conversion factor that relates wheels to tricycles. You can write two conversion factors relating wheels to tricycles.

$$\frac{3\text{ W}}{1\text{ FSW}_3\text{HP}_2} \text{ and } \frac{1\text{ FSW}_3\text{HP}_2}{3\text{ W}}$$

When using conversion factors, remember to cancel like units when they are in both the numerator and denominator. This tells you that you are using the correct conversion factor.

The desired unit is W; so use the conversion factor on the left. Multiply the number of tricycles by the conversion factor.

$$640\ \cancel{FSW_3HP_2} \times \frac{3\text{ W}}{1\ \cancel{FSW_3HP_2}} = 1920\text{ W}$$

3 Evaluate **Does the result make sense?** If three wheels are required for each tricycle and more than 600 tricycles are being made, then a number of wheels in excess of 1800 is a logical answer. The unit of the known (FSW_3HP_2) cancels, and the answer has the correct unit (W).

1. Travel Time has decided to make 288 tricycles each day. How many tricycle seats, wheels, and pedals are needed for each day?

2. Write an equation that gives your own "recipe" for making a skateboard.

Foundations for Math

RATIOS AND PROPORTIONS Explain that a ratio represents the relationship between two quantities. For example, the ratio 1:3 can be used to represent the relationship 1 handlebar to 3 wheels in **Sample Problem 12.1,** or 1 molecule of nitrogen to 3 molecules of hydrogen in the balanced equation for ammonia. Explain that the ratio may not be a true representation if the equations are not balanced. Set two ratios equal to each other to show students how a proportion can be used to determine an unknown quantity. Solve the proportion by using cross products, and point out how the units cancel, leaving you with the desired unit of the quantity you were trying to find.

Foundations for Reading

BUILD VOCABULARY Have students use an analogy of ingredients and product of a recipe to explain their interpretation of stoichiometry.

READING STRATEGY Have students construct tables similar to Figure 12.2 to help them understand the quantities involved with any balanced chemical equation they encounter in this chapter.

Explain

Using Equations

START A CONVERSATION Direct students to look at the visual representation of a tricycle. Then write this statement on the board "A frame, a seat, wheels, a handlebar, and pedals are needed to assemble a complete tricycle." **Ask** How can this statement be revised so that it more accurately describes the process of assembling a tricycle? *(One frame, one seat, three wheels, one handlebar, and two pedals are needed to assemble a complete tricycle.)*

MAKE A CONNECTION Write the equation on the board.

$$F + S + 3W + H + 2P \rightarrow FSW_3HP_2$$

Point out that the balanced equation contains information that not only relates reactants to product but relates one reactant to another.

Ask Describe a method you can use to determine how many handlebars are needed to complete tricycles if you know how many pedals are available. *(Set up and solve a proportion.)*

Sample Practice Problems

A. Set up and solve a proportion to find how many handlebars are needed to complete tricycles if you know there are 24 pedals available. (*12*)

B. How many handlebars are needed to complete tricycles if 24 seats are available? (*24*)

C. How many handlebars are needed to complete tricycles if 24 wheels are available? (*8*)

Answers

1. 288 seats, 864 wheels, 576 pedals

2. Answers will vary but should include the correct number of "parts" to make the product.

Explain

Chemical Equations

START A CONVERSATION Write the following two chemical reactions on the board:

A. $CuO(s) + NH_3(aq) \rightarrow Cu(s) + H_2O(l) + N_2(g)$

B. $4NH_3(g) + 5O_2(g) \rightarrow 4NO(g) + 6H_2O(g)$

Ask Which equation can be used in its current form to determine how much product is formed by the reactants? *(equation A)*

Ask If you used equation A. in its current form to make stoichiometric calculations, why would your answers not be accurate? *(The equation is not balanced.)*

Misconception Alert

Make sure students understand that they cannot balance an equation by changing the subscripts in a formula. A change to the subscripts causes the chemical identity of the substance to change.

CHEMISTRY & YOU Use a balanced chemical equation.

Extend

Connect to ENVIRONMENTAL SCIENCE

Tell students that Earth's atmosphere contains 0.01 parts per million of ammonia, and small amounts of ammonia occur in volcanic gases. Most ammonia cycles through the living world without returning to the atmosphere. Ammonia plays a role in several stages of the nitrogen cycle. Nitrogen-fixing bacteria form nodules, or swellings, on the roots of plants in the legume family, such as beans and clover plants. These bacteria change atmospheric nitrogen into ammonia molecules or ammonium ions. Other bacteria break down the nitrogenous material in dead plants and animals into ammonia molecules. Certain soil bacteria oxidize these molecules into nitrate ions, the form readily absorbed by plant roots. When a plant dies, this cycle begins again.

Have students write and balance the equations involved in the stages of the nitrogen cycle that involve ammonia. Then have them identify the parts of the nitrogen cycle where these reactions take place.

CHEMISTRY & YOU

Q: How can you determine the amount of each reactant you need to make a product?

READING SUPPORT

Build Vocabulary: *Word Origins* *Stoichiometry* comes from the combination of the Greek words *stoikheioin,* meaning "element," and *metron,* meaning "to measure." Stoichiometry is the calculation of amounts of substances involved in chemical reactions. ***What do you first need to know about a chemical reaction before doing stoichiometry calculations?***

Balanced Chemical Equations Nearly everything you use is manufactured from chemicals—soaps, shampoos and conditioners, CDs, cosmetics, medicines, and clothes. When manufacturing such items, the cost of making them cannot be greater than the price at which they are sold. Otherwise, the manufacturer will not make a profit. Therefore, the chemical processes used in manufacturing must be carried out economically. A situation like this is where balanced equations help.

A balanced chemical equation tells you what amounts of reactants to mix and what amount of a product to expect. **Chemists use balanced chemical equations as a basis to calculate how much reactant is needed or how much product will be formed in a reaction.** When you know the quantity of one substance in a reaction, you can calculate the quantity of any other substance consumed or created in the reaction. Quantity usually means the amount of a substance expressed in grams or moles. However, quantity could just as well be in liters, tons, or molecules.

The calculation of quantities in chemical reactions is a subject of chemistry called **stoichiometry.** Calculations using balanced equations are called stoichiometric calculations. For chemists, stoichiometry is a form of bookkeeping. For example, accountants can track income, expenditures, and profits for a small business by tallying each in dollars and cents. Chemists can track reactants and products in a reaction by stoichiometry. It allows chemists to tally the amounts of reactants and products using ratios of moles or representative particles derived from chemical equations.

Chemical Equations

In terms of what quantities can you interpret a balanced chemical equation?

In gardens such as the one shown in Figure 12.1, fertilizers are often used to improve the growth of flowers. Ammonia is widely used as a fertilizer. Ammonia is produced industrially by the reaction of nitrogen with hydrogen.

$$N_2(g) + 3H_2(g) \longrightarrow 2NH_3(g)$$

The balanced chemical equation tells you the relative amounts of reactants and product in the reaction. However, your interpretation of the equation depends on how you quantify the reactants and products. **A balanced chemical equation can be interpreted in terms of different quantities, including numbers of atoms, molecules, or moles; mass; and volume.** As you study stoichiometry, you will learn how to interpret a chemical equation in terms of any of these quantities.

Number of Atoms At the atomic level, a balanced equation indicates the number and types of atoms that are rearranged to make the product or products. Remember, both the number and types of atoms are not changed in a reaction. In the synthesis of ammonia, the reactants are composed of two atoms of nitrogen and six atoms of hydrogen. These eight atoms are recombined in the product.

2 atoms N + 6 atoms H ⟶ 2 atoms N and 6 atoms H

8 atoms ⟶ 8 atoms

Differentiated Instruction

L1 LESS PROFICIENT READERS Have students create a two-column table with the following row headings: *Number of Atoms, Number of Molecules, Moles, Mass, and Volume*. Then have students complete their tables by writing an example of the formation of ammonia, $N_2(g) + 3H_2(g) \rightarrow 2NH_3(g)$, and how the corresponding quantity is interpreted from the balanced equation.

ELL ENGLISH LANGUAGE LEARNERS Divide students into groups of five. Have each group draw or model the formation of ammonia, $N_2(g) + 3H_2(g) \rightarrow 2NH_3(g)$. Then have each student in the group read one of the paragraphs in the Chemical Equations section. Students should use the model to explain the concept in their paragraph.

L3 ADVANCED STUDENTS Ask students to explain to the class the meaning of STP, the values of STP, the molar volume of any gas at STP, and how many particles it contains. *(standard temperature and pressure; 0°C and 101.3 kPa; 22.4 L/mol; 22.4 L of any ideal gas at STP contains 6.02×10^{23} particles of that gas.)*

Number of Molecules The balanced equation indicates that one molecule of nitrogen reacts with three molecules of hydrogen. Nitrogen and hydrogen will always react to form ammonia in a 1:3:2 ratio of molecules. If you could make 10 molecules of nitrogen react with 30 molecules of hydrogen, you would expect to get 20 molecules of ammonia. Of course, it is not practical to count such small numbers of molecules and allow them to react. You could, however, take Avogadro's number of nitrogen molecules and make them react with three times Avogadro's number of hydrogen molecules. This value would be the same 1:3 ratio of molecules of reactants. The reaction would form two times Avogadro's number of ammonia molecules.

$$1 \times \frac{6.02 \times 10^{23}\ \text{molecules } N_2}{} + 3 \times \frac{6.02 \times 10^{23}\ \text{molecules } H_2}{} \longrightarrow 2 \times \frac{6.02 \times 10^{23}\ \text{molecules } NH_3}{}$$

Moles You know that Avogrado's number of representative particles is equal to one mole of a substance. Therefore, since a balanced chemical equation tells you the number of representative particles, it also tells you the number of moles. The coefficients of a balanced chemical equation indicate the relative numbers of moles of reactants and products in a chemical reaction. These numbers are the most important pieces of information that a balanced chemical equation provides. Using this information, you can calculate the amounts of reactants and products. In the synthesis of ammonia, one mole of nitrogen molecules reacts with three moles of hydrogen molecules to form two moles of ammonia molecules. As you can see from this reaction, the total number of moles of reactants does not equal the total number of moles of product.

$$1\ \text{mol } N_2 + 3\ \text{mol } H_2 \longrightarrow 2\ \text{mol } NH_3$$

Mass A balanced chemical equation obeys the law of conservation of mass. This law states that mass can be neither created nor destroyed in an ordinary chemical or physical process. As you recall, the number and type of atoms does not change in a chemical reaction. Therefore, the total mass of the atoms in the reaction does not change. Using the mole relationship, you can relate mass to the number of atoms in the chemical equation. The mass of 1 mol of N_2 (28.0 g) plus the mass of 3 mol of H_2 (6.0 g) equals the mass of 2 mol of NH_3 (34.0 g). Although the number of moles of reactants does not equal the number of moles of product, the total number of grams of reactants does equal the total number of grams of product.

$$28.0\ \text{g } N_2 + (3 \times 2.0\ \text{g } H_2) \longrightarrow (2 \times 17.0\ \text{g } NH_3)$$
$$34.0\ \text{g} \longrightarrow 34.0\ \text{g}$$

Volume If you assume standard temperature and pressure, the equation also tells you about the volumes of gases. Recall that 1 mol of any gas at STP occupies a volume of 22.4 L. The equation indicates that 22.4 L of N_2 reacts with 67.2 L (3 × 22.4 L) of H_2. This reaction forms 44.8 L (2 × 22.4 L) of NH_3.

$$22.4\ \text{L } N_2 + 67.2\ \text{L } H_2 \longrightarrow 44.8\ \text{L } NH_3$$

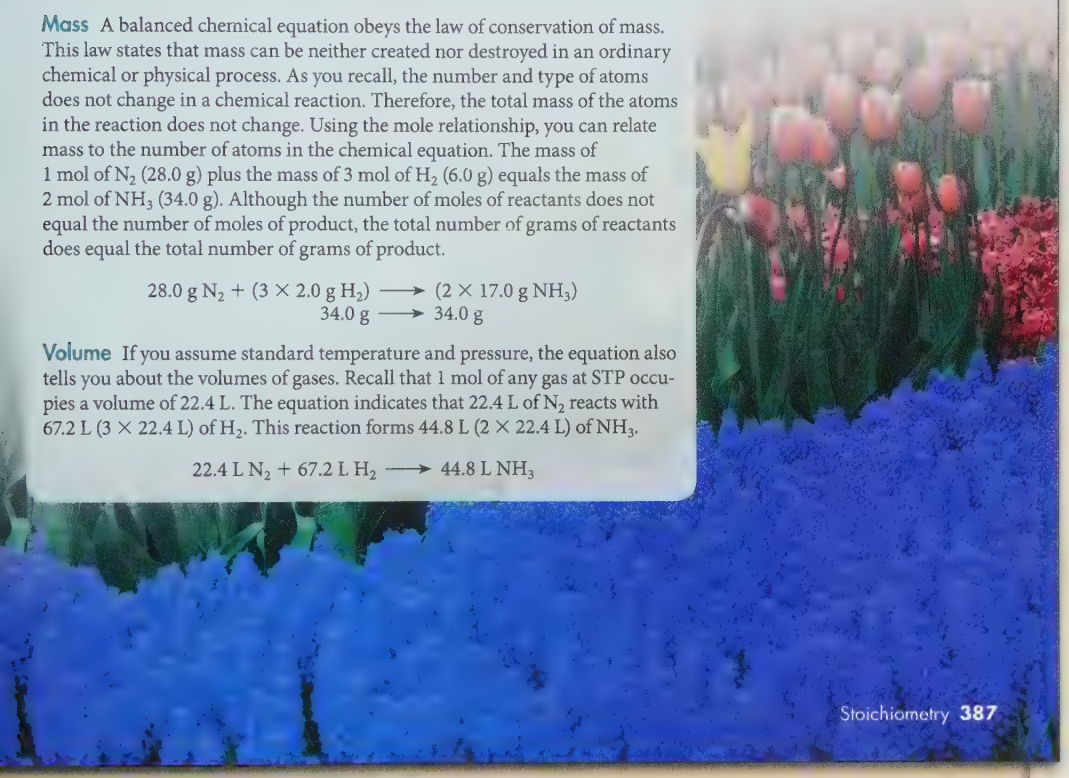

Figure 12.1 Use of Ammonia Gardeners use ammonium salts as fertilizer. The nitrogen in these salts is essential to plant growth.

UbD Check for Understanding

The Essential Question **What is the purpose of balanced chemical equations in stoichiometric calculations?**

Assess students' knowledge of stoichiometry by asking them to interpret the following equation in terms of atoms, molecules, moles, mass, and/or volume.

$$2KClO_3(s) \rightarrow 2KCl(s) + 3O_2(g)$$

Elicit oral responses from students to determine if they understand why chemical equations must be balanced.

Explore

Teacher Demo

PURPOSE Students interpret a balanced equation of the reaction of magnesium and hydrochloric acid.

MATERIALS 2.5–3.5-cm strip of magnesium, 50 mL 1*M* HCl(*aq*) in a 100-mL beaker, baking soda

SAFETY Wear safety glasses and an apron. Neutralize remaining HCl(*aq*) with baking soda before flushing down the drain.

PROCEDURE Identify the two reactants as magnesium and hydrochloric acid. Have students observe the reaction as you carefully add the magnesium strip to the acid. Ask students to write a balanced chemical equation for the reaction of magnesium and hydrochloric acid. ($Mg(s) + 2HCl(aq) \rightarrow MgCl_2(aq) + H_2(g)$) Have students interpret the equation in terms of particles, moles, and molar masses.

EXPECTED OUTCOME Students should express the balanced equation at the particle level as one atom of magnesium reacts with two molecules of hydrogen chloride to produce one formula unit of magnesium chloride and one molecule of hydrogen gas. Similarly, one mole of magnesium reacts with two moles of hydrogen chloride to produce one mole of magnesium chloride and one mole of hydrogen gas. Finally, 24.31 g Mg + 72.92 g HCl produces 95.21 g $MgCl_2$ + 2.02 g H_2.

Explain

CRITICAL THINKING Have students try to find a counterexample to the statement "The conservation of moles exists for every chemical reaction," and have them try to find a counterexample to the statement "The conservation of mass exists for every chemical reaction" to prove that the law of conservation exists for mass but not for moles. *(Answers may vary.)*

Sample Practice Problems

Balance the following equation:

$$C_5H_{12}(g) + O_2(g) \rightarrow CO_2(g) + H_2O(g)$$

Interpret the balanced equation in terms of relative number of moles, volumes of gas at STP, and masses of reactants and products. *(1 mol C_5H_{12}(g) + 8 mol O_2(g) → 5 mol CO_2(g) + 6 mol H_2O(g); 22.4 L C_5H_{12}(g) + 179 L O_2(g) → 112 L CO_2(g) + 134 L H_2O(g); 328 g reactants → 328 g products)*

SampleProblem 12.2

Interpreting a Balanced Chemical Equation

Hydrogen sulfide, which smells like rotten eggs, is found in volcanic gases. The balanced equation for the burning of hydrogen sulfide is

$$2H_2S(g) + 3O_2(g) \longrightarrow 2SO_2(g) + 2H_2O(g)$$

Interpret this equation in terms of

a. numbers of representative particles and moles.

b. masses of reactants and products.

Remember that atoms and molecules are both representative particles. In this equation, all the reactants and products are molecules; so all the representative particles are molecules.

1 Analyze Identify the relevant concepts. The coefficients in the balanced equation give the relative number of representative particles and moles of reactants and products. A balanced chemical equation obeys the law of conservation of mass.

2 Solve Apply concepts to this situation.

Use the coefficients in the balanced equation to identify the number of representative particles and moles.

a. 2 molecules H_2S + 3 molecules O_2 ⟶ 2 molecules SO_2 + 2 molecules H_2O

2 mol H_2S + 3 mol O_2 ⟶ 2 mol SO_2 + 2 mol H_2O

Use the periodic table to calculate the molar mass of each reactant and product.

b. 1 mol H_2S = 34.1 g H_2S

1 mol O_2 = 32.0 g O_2

1 mol SO_2 = 64.1 g SO_2

1 mol H_2O = 18.0 g H_2O

Multiply the number of moles of each reactant and product by its molar mass.

2 mol H_2S + 3 mol O_2 ⟶ 2 mol SO_2 + 2 mol H_2O.

$$\left(2\,\text{mol} \times 34.1\,\frac{\text{g}}{\text{mol}}\right) + \left(3\,\text{mol} \times 32.0\,\frac{\text{g}}{\text{mol}}\right) \longrightarrow \left(2\,\text{mol} \times 64.1\,\frac{\text{g}}{\text{mol}}\right) + \left(2\,\text{mol} \times 18.0\,\frac{\text{g}}{\text{mol}}\right)$$

68.2 g H_2S + 96.0 g O_2 ⟶ 128.2 g SO_2 + 36.0 g H_2O

164.2 g = 164.2 g

3. Interpret the equation for the formation of water from its elements in terms of numbers of molecules and moles, and volumes of gases at STP.

$$2H_2(g) + O_2(g) \longrightarrow 2H_2O(g)$$

4. Balance the following equation:

$$C_2H_4(g) + O_2(g) \longrightarrow CO_2(g) + H_2O(g)$$

Interpret the balanced equation in terms of relative numbers of moles, volumes of gas at STP, and masses of reactants and products.

Foundations for Math

ORDER OF OPERATIONS Explain that students should always follow the order of operations to correctly determine the answer to a mathematical problem. Remind students of PEMDAS, a mnemonic commonly used to help students remember the order of operations:

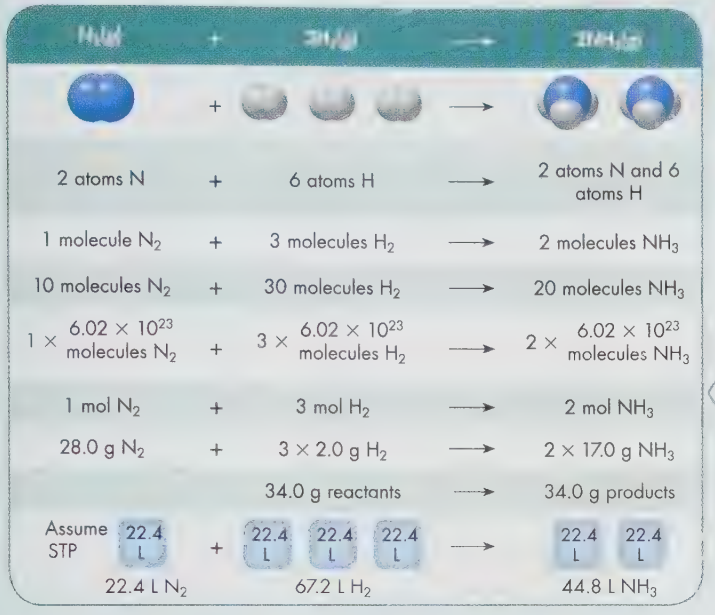
Please **E**xcuse **M**y **D**ear **A**unt **S**ally: **P**arentheses first, **E**xponents next, **M**ultiplication and **D**ivision from left to right, **A**ddition and **S**ubtraction from left to right

In **Sample Problem 12.2 part b,** point out that to correctly determine the total mass of the reactants and the total mass of the products, multiplication is computed prior to addition.

Figure 12.2 summarizes the information derived from the balanced chemical equation for the formation of ammonia. As you can see, the mass of the reactants equals the mass of the products. In addition, the number of atoms of each type in the reactants equals the number of atoms of each type in the product. Mass and atoms are conserved in every chemical reaction. However, molecules, formula units, moles, and volumes are not necessarily conserved—although they may be. Consider, for example, the formation of hydrogen iodide.

$$H_2(g) + I_2(g) \longrightarrow 2HI(g)$$

In this reaction, molecules, moles, and volume are all conserved. But in the majority of chemical reactions, they are not.



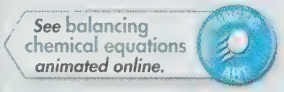


Figure 12.2 Interpreting a Balanced Chemical Equation The balanced chemical equation for the formation of ammonia can be interpreted in several ways.
Predict *How many molecules of NH_3 could be made from 5 molecules of N_2 and 15 molecules of H_2?*

12.1 LessonCheck

5. Explain How do chemists use balanced equations?

6. Identify Chemical reactions can be described in terms of what quantities?

7. Explain How is a balanced equation similar to a recipe?

8. Identify What quantities are always conserved in chemical reactions?

9. Apply Concepts Interpret the given equation in terms of relative numbers of representative particles, numbers of moles, and masses of reactants and products.

$$2K(s) + 2H_2O(l) \longrightarrow 2KOH(aq) + H_2(g)$$

10. Apply Concepts Balance this equation:

$$C_2H_5OH(l) + O_2(g) \longrightarrow CO_2(g) + H_2O(g)$$

Show that the balanced equation obeys the law of conservation of mass.

Lesson Check Answers

5. as a basis to calculate how much reactant is needed or product is formed in a reaction

6. numbers of atoms, molecules, or moles; mass; and volumes

7. Both a balanced equation and a recipe give quantitative information about the starting and end materials.

8. mass and atoms

9. 2 atoms K + 2 molecules H_2O → 2 formula units KOH + 1 molecule H_2
2 mol K + 2 mol H_2O → 2 mol KOH + 1 mol H_2
78.2 g K + 36.0 g H_2O → 112.2 g KOH + 2.0 g H_2

10. $C_2H_5OH + 3O_2 \rightarrow 2CO_2 + 3H_2O$
46.0 g C_2H_5OH + 96.0 g O_2 → 88.0 g CO_2 + 54.0 g H_2O
142.0 g reactants → 142.0 g products

USE VISUALS Direct students to Figure 12.3. Remind students that the term *STP* represents "standard temperature and pressure." **Ask** What are the values of STP? *(0°C and 101.3 kPa)* **Ask** Why is the volume of a gas usually measured at STP? *(because its volume varies with temperature and pressure)* **Ask** What is the molar volume of any gas at STP? *(22.4L/mol of any ideal gas at STP)* How many particles does it contain? *(22.4 L of any gas contains 6.02 x 10^{23} particles.)*

Evaluate

Informal Assessment

Divide the class into three teams. Have Team 1 write five balanced chemical equations on separate note cards and place them in a box. Also have them create four note cards with one word per card: *atoms, molecules, mass, moles*. Have Team 2 draw an equation from the box, and have Team 3 randomly select one of the four cards. Team 3 tells Team 2 which quantitative relationship of their selected equation they have to determine within a one minute time period. Rotate teams after each round. Students can be assessed on participation, correctness of answers, and creativity of balanced equations.

Reteach

Construct a "gizmo" from a large flask (F) fitted with a one-hole stopper (S) and glass tube (T). Show students the gizmo and write its balanced equation on the board as the following:

$$\_\_F + \_\_S + \_\_T = \_\_FST.$$

Explain that any counted quantity such as 2 dozen or 12 ten-packs could be used to fill any set of four blanks in the equation. However, a physical quantity such as 10 kg would not balance the equation. Have students explain why.

Answers

FIGURE 12.2 10 molecules NH_3

3. 2 molecules H_2 + 1 molecule O_2 → 2 molecules H_2O
2 mol H_2 + 1 mol O_2 → 2 mol H_2O
44.8 L H_2 + 22.4 L O_2 → 44.8 L H_2O

4. 1 mol C_2H_2 + 5 mol O_2 → 4 mol CO_2 + 2 mol H_2O
44.8 L C_2H_2 + 112 L O_2 → 89.6 L CO_2 + 44.8 L H_2O
212 g reactants → 212 g products

LESSON 12.2

Key Objectives

12.2.1 Explain how mole ratios are used in chemical calculations.

12.2.2 Explain the general procedure for solving a stoichiometric problem.

CHEMISTRY & YOU

Q: *How do manufacturers know how to make enough of their desired product?* Chemical plants produce ammonia by combining nitrogen with hydrogen. If too much ammonia is produced, then it might be wasted. But if too little is produced, then there might not be enough for all their customers. In this lesson, you will learn how to use a balanced chemical equation to calculate the amount of product formed in a chemical reaction.

Key Questions

How are mole ratios used in chemical calculations?

What is the general procedure for solving a stoichiometric problem?

Vocabulary

- mole ratio

Writing and Using Mole Ratios

How are mole ratios used in chemical calculations?

As you learned in the previous lesson, a balanced chemical equation provides a great deal of quantitative information. It relates particles (atoms, molecules, formula units), moles of substances, and masses. A balanced chemical equation also is essential for all calculations involving amounts of reactants and products. For example, suppose you know the number of moles of one substance. The balanced chemical equation allows you to determine the number of moles of all other substances in the reaction.

Look again at the balanced equation for the production of ammonia.

$$N_2(g) + 3H_2(g) \longrightarrow 2NH_3(g)$$

The most important interpretation of this equation is that 1 mol of nitrogen reacts with 3 mol of hydrogen to form 2 mol of ammonia. Based on this interpretation, you can write ratios that relate moles of reactants to moles of product. A **mole ratio** is a conversion factor derived from the coefficients of a balanced chemical equation interpreted in terms of moles. **In chemical calculations, mole ratios are used to convert between a given number of moles of a reactant or product to moles of a different reactant or product.** Three mole ratios derived from the balanced equation above are

$$\frac{1 \text{ mol } N_2}{3 \text{ mol } H_2} \quad \frac{2 \text{ mol } NH_3}{1 \text{ mol } N_2} \quad \frac{3 \text{ mol } H_2}{2 \text{ mol } NH_3}$$

Mole-Mole Calculations In the mole ratio below, W is the unknown, wanted, quantity and G is the given quantity. The values of a and b are the coefficients from the balanced equation. Thus, a general solution for a mole-mole problem, such as Sample Problem 12.3, is given by

$$a \text{ mol } G \times \frac{b \text{ mol } W}{a \text{ mol } G} = \frac{xb}{a} \text{ mol } W$$

Given | Mole ratio | Calculated

Focus on ELL

1 CONTENT AND LANGUAGE Present academic vocabulary that appears in the lesson, such as *instantaneously*, *conversion*, and *excess*. Pair students and have them find these words in the lesson and use context clues to predict their meanings. Have students share their interpretations with the class.

2 FRONTLOAD THE LESSON Have students discuss their experience with ratios from mathematics class. To check understanding, have students determine the ratio of males to females in the class and the ratio of each gender to total students.

3 COMPREHENSIBLE INPUT Explain **Sample Problem 12.3** using a diagram. Write each reactant using a different color. Continue to use the corresponding color throughout the calculation. Speak clearly and slowly, and use block arrows to show the steps of the process.

Sample Problem 12.3

Calculating Moles of a Product

How many moles of NH_3 are produced when 0.60 mol of nitrogen reacts with hydrogen?

1 Analyze **List the known and the unknown.** The conversion is mol N_2 ⟶ mol NH_3. According to the balanced equation, 1 mol N_2 combines with 3 mol H_2 to produce 2 mol NH_3. To determine the number of moles of NH_3, the given quantity of N_2 is multiplied by the form of the mole ratio from the balanced equation that allows the given unit to cancel.

KNOWN

moles of nitrogen = 0.60 mol N_2

UNKNOWN

moles of ammonia = ? mol NH_3

2 Calculate **Solve for the unknown.**

Write the mole ratio that will allow you to convert from moles N_2 to moles NH_3.

$$\frac{2 \text{ mol } NH_3}{1 \text{ mol } N_2}$$

Multiply the given quantity of N_2 by the mole ratio in order to find the moles of NH_3.

$$0.60 \text{ mol } N_2 \times \frac{2 \text{ mol } NH_3}{1 \text{ mol } N_2} = 1.2 \text{ mol } NH_3$$

3 Evaluate **Does the result make sense?** The ratio of 1.2 mol NH_3 to 0.60 mol N_2 is 2:1, as predicted by the balanced equation.

Remember that the mole ratio must have N_2 on the bottom so that the mol N_2 in the mol ratio will cancel with mol N_2 in the known.

11. This equation shows the formation of aluminum oxide, which is found on the surface of aluminum objects exposed to the air.

$$4Al(s) + 3O_2(g) \longrightarrow 2Al_2O_3(s)$$

a. Write the six mole ratios that can be derived from this equation.

b. How many moles of aluminum are needed to form 3.7 mol Al_2O_3?

12. According to the equation in Problem 11,

a. How many moles of oxygen are required to react completely with 14.8 mol Al?

b. How many moles of Al_2O_3 are formed when 0.78 mol O_2 reacts with aluminum?

Mass-Mass Calculations No laboratory balance can measure substances directly in moles. Instead, the amount of a substance is usually determined by measuring its mass in grams. From the mass of a reactant or product, the mass of any other reactant or product in a given chemical equation can be calculated. The mole interpretation of a balanced equation is the basis for this conversion. If the given sample is measured in grams, then the mass can be converted to moles by using the molar mass. Then the mole ratio from the balanced equation can be used to calculate the number of moles of the unknown. If it is the mass of the unknown that needs to be determined, the number of moles of the unknown can be multiplied by the molar mass. As in mole-mole calculations, the unknown can be either a reactant or a product.

Foundations for Math

DIMENSIONAL ANALYSIS Remind students that to solve a problem by using dimensional analysis, they need to first find the conversion factor. A conversion factor is a ratio of equivalent measurements. **Sample problem 12.3** asks students to find the moles of ammonia produced, so the answer needs to be in units of "moles of ammonia."

Remind students that they can multiply any quantity by anything equal to 1 without changing the value of the quantity.

Since the number of moles of nitrogen is given, the ratio of moles of nitrogen to moles of ammonia can be used as the conversion factor.

Foundations for Reading

BUILD VOCABULARY Have students paraphrase the meaning of **mole ratio** using words or symbols. Guide students to use what they have already learned about balanced chemical equations from the previous lesson and about ratios from mathematics class to form their definitions. Have students read their definitions to the class.

READING STRATEGY As students read the section about Mass-Mass Calculations, have them identify and list the main ideas presented by the text.

Explain

Writing and Using Mole Ratios

START A CONVERSATION Discuss with students what they know about the relationship of the total mass of the reactants and the total mass of the products in a chemical reaction. **Ask** Why do you think this relationship is important when trying to determine quantitative information about a chemical reaction? *(Answers will vary.)*

Be sure students understand the difference between moles and mole ratio. Point out to students that moles are always involved in stoichiometry problems. Mole ratios are used to convert from one substance in the balanced equation to another substance.

Sample Practice Problem

Iron(III) oxide reacts with carbon monoxide to yield iron and carbon dioxide in the following reaction:

$$Fe_2O_3(s) + 3CO(g) \rightarrow 2Fe(s) + 3CO_2(g)$$

A. How many mole ratios can be derived from this equation? What are they? *(12;* $\frac{([Fe]_2O_3)}{(3CO)}, \frac{(3CO)}{([Fe]_2O_3)}, \frac{([Fe]_2O_3)}{(2Fe)}, \frac{(2Fe)}{([Fe]_2O_3)}$,

B. How many moles of Fe are produced from 1.8 mol of Fe_2O_3? *(3.6 mol)*

Answers

11. a. $\frac{4 \text{ mol Al}}{3 \text{ mol } O_2}$ $\frac{3 \text{ mol } O_2}{4 \text{ mol Al}}$ $\frac{4 \text{ mol Al}}{2 \text{ mol } Al_2O_3}$ $\frac{2 \text{ mol } Al_2O_3}{4 \text{ mol Al}}$ $\frac{3 \text{ mol } O_2}{2 \text{ mol } Al_2O_3}$ $\frac{2 \text{ mol } Al_2O_3}{3 \text{ mol } O_2}$

b. 7.4 mol

12. a. 11.1 mol

b. 0.52 mol

Explore

Teacher Demo

PURPOSE Students interpret a balanced equation in terms of moles and mass.

MATERIALS Prior to the demonstration, prepare 0.1*M* solutions of potassium iodide and lead(II) nitrate. Measure 50.0 mL of $Pb(NO_3)_2$ and 150 mL of KI into separate 250-mL beakers.

SAFETY Wear safety glasses and an apron.

PROCEDURE Tell students that you are going to mix 0.005 mole of lead(II) nitrate with excess potassium iodide. Have students observe as you combine both solutions in the 250-mL beaker. Have students write a balanced chemical equation for the observed reaction.

$[2KI(aq) + Pb(NO_3)_2(aq) \rightarrow 2KNO_3(aq) + PbI_2(s)]$

Have students predict the number of moles of product produced. *(0.005 mole PbI_2 assuming the reaction was complete)* Note that, in an actual reaction, the amounts of reactants often are not present in the mole ratios predicted by the coefficients in a balanced equation. Explain the importance of the mole ratios in an equation for calculating relative quantities. **Ask** What is the mass of lead(II) nitrate reacted and the mass of lead(II) iodide produced? *(1.66 g $Pb(NO_3)_2$ and 2.30 g PbI_2)*

EXPECTED OUTCOME A bright yellow precipitate will form.

Misconception Alert

Students sometimes try to do mass-mass conversions by incorrectly using the mole ratio as a mass ratio. That is, they use grams instead of moles as the units in the mole ratio and then skip the mass-mole conversion step. Stress that because the number of grams in one mole of a substance varies with its molar mass, a mass-mole conversion is a necessary intermediate step in mass-mass stoichiometric problems.

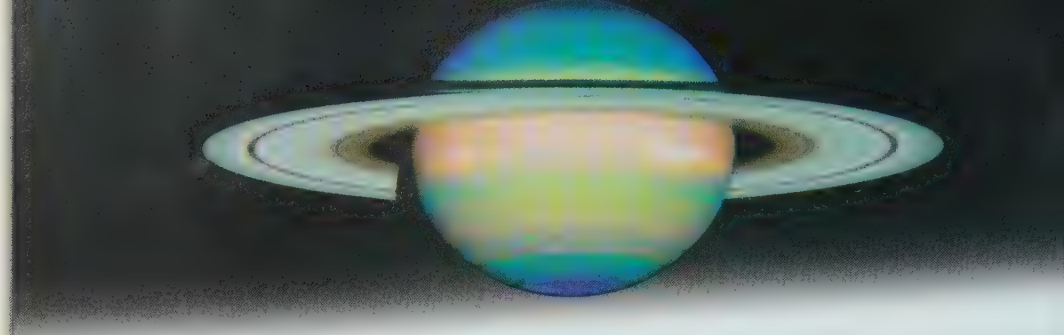

Figure 12.3 Ammonia in Space In this Hubble Space Telescope image, clouds of condensed ammonia are visible covering the surface of Saturn.

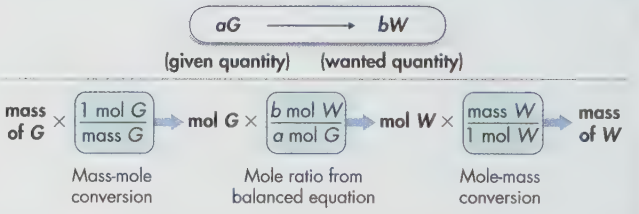
Steps for Solving a Mass-Mass Problem Mass-mass problems are solved in basically the same way as mole-mole problems. The steps for the mass-mass conversion of any given mass (*G*) to any wanted mass (*W*) are outlined below.

1. Change the mass of *G* to moles of *G* (mass *G* ⟶ mol *G*) by using the molar mass of *G*.

$$\text{mass } G \times \frac{1 \text{ mol } G}{\text{molar mass } G} = \text{mol } G$$

2. Change the moles of *G* to moles of *W* (mol *G* ⟶ mol *W*) by using the mole ratio from the balanced equation.



$$\text{mol } G \times \frac{b \text{ mol } W}{a \text{ mol } G} = \text{mol } W$$

3. Change the moles of *W* to grams of *W* (mol *W* ⟶ mass *W*) by using the molar mass of *W*.

$$\text{mol } W \times \frac{\text{molar mass } W}{1 \text{ mol } W} = \text{mass } W$$

Figure 12.4 shows another way to represent the steps for doing mole-mass and mass-mole stoichiometric calculations. For a mole-mass problem, the first conversion (from mass to moles) is skipped. For a mass-mole problem, the last conversion (from moles to mass) is skipped. You can use parts of the three-step process shown in Figure 12.4 as they are appropriate to the problem you are solving.

Figure 12.4 Mass-Mass Conversion Steps This general solution diagram indicates the steps necessary to solve a mass-mass stoichiometry problem: Convert mass to moles, use the mole ratio, and then convert moles to mass.
Infer ***Is the given always a reactant?***

Professional Development Note

Atmospheric Ammonia

Ammonia is found in trace amounts in the atmospheres of three Jovian planets—Jupiter, Saturn, and Uranus. In Jupiter's atmosphere, the clouds of ammonia consist of frozen ammonia droplets changing to liquid ammonia droplets nearer the planet's surface. Because of colder temperatures, the ammonia clouds in the atmosphere of Saturn and Uranus consist of frozen ammonia droplets.

Sample Problem 12.4

Calculating the Mass of a Product

Ammonia (NH_3) clouds are present around some planets, as in Figure 12.3. Calculate the number of grams of NH_3 produced by the reaction of 5.40 g of hydrogen with an excess of nitrogen. The balanced equation is

$$N_2(g) + 3H_2(g) \longrightarrow 2NH_3(g)$$

1 Analyze **List the knowns and the unknown.**

The mass of hydrogen will be used to find the mass of ammonia: g H_2 ⟶ g NH_3. The coefficients of the balanced equation show that 3 mol H_2 reacts with 1 mol N_2 to produce 2 mol NH_3. The following steps are necessary to determine the mass of ammonia:

g H_2 ⟶ mol H_2 ⟶ mol NH_3 ⟶ g NH_3

KNOWNS

mass of hydrogen = 5.40 g H_2

2 mol NH_3/3 mol H_2 (from balanced equation)

1 mol H_2 = 2.0 g H_2 (molar mass)

1 mol NH_3 = 17.0 g NH_3 (molar mass)

UNKNOWN

mass of ammonia = ? g NH_3

2 Calculate **Solve for the unknown.**

Start with the given quantity, and convert from mass to moles.

$$5.40\,\text{g}\,H_2 \times \frac{1\,\text{mol}\,H_2}{2.0\,\text{g}\,H_2}$$

Don't forget to cancel the units at each step.

Then convert from moles of reactant to moles of product by using the correct mole ratio.

$$5.40\,\text{g}\,H_2 \times \frac{1\,\text{mol}\,H_2}{2.0\,\text{g}\,H_2} \times \frac{2\,\text{mol}\,NH_3}{3\,\text{mol}\,H_2}$$

g H_2 ⟶ mol H_2 ⟶ mol NH_3 ⟶ g NH_3

Finish by converting from moles to grams. Use the molar mass of NH_3.

$$5.40\,\text{g}\,H_2 \times \frac{1\,\text{mol}\,H_2}{2.0\,\text{g}\,H_2} \times \frac{2\,\text{mol}\,NH_3}{3\,\text{mol}\,H_2} \times \frac{17.0\,\text{g}\,NH_3}{1\,\text{mol}\,NH_3} = 31\,\text{g}\,NH_3$$

Given quantity | Change given unit to moles | Mole ratio | Change moles to grams

3 Evaluate **Does the result make sense?** Because there are three conversion factors involved in this solution, it is more difficult to estimate an answer. However, because the molar mass of NH_3 is substantially greater than the molar mass of H_2, the answer should have a larger mass than the given mass. The answer should have two significant figures.

13. Acetylene gas (C_2H_2) is produced by adding water to calcium carbide (CaC_2).

$$CaC_2(s) + 2H_2O(l) \longrightarrow C_2H_2(g) + Ca(OH)_2(aq)$$

How many grams of acetylene are produced by adding water to 5.00 g CaC_2?

14. Use the equation in Question 13 to determine how many moles of CaC_2 are needed to react completely with 49.0 g H_2O.

Foundations for Math

SIGNIFICANT FIGURES The significant figures in a measurement are all the digits known with certainty plus one estimated digit.

The number of significant figures of a product or quotient should equal the least number of significant figures of any measurement in the calculation. For example, 5.5 cm × 2.24 cm = 12 cm^2; notice that the product has 2 significant figures, the same as 5.5 cm.

The number of decimal places of a sum or difference should equal the least number of decimal places in any of the measurements being added or subtracted. For example, 5.5 cm + 2.24 cm = 7.7 cm; notice that the sum has 2 significant figures, the same as 5.5 cm.

Explain

START A CONVERSATION Take a quick vote in class to see who believes there is a "law of conservation of moles." Discuss the reasons why students believe this law exists. **Ask** In the following reaction, $2H_2O(l) \rightarrow 2H_2(g) + O_2(g)$, is the number of moles of the products greater than, less than, or equal to the number of moles of the reactant? *(greater than)*

Ask In the following reaction, $2Mg(s) + O_2(g) \rightarrow 2MgO(s)$, is the number of moles of product greater than, less than, or equal to the number of moles of the reactants? *(less than)*

Guide students to understand that there are many types of reactions where reactants can combine or decompose to produce fewer or more moles of product. Explain that although the total mass of reactants and products is constant, the number of moles of particles can increase or decrease depending on the final grouping of atoms.

Sample Practice Problem

Rust (Fe_2O_3) is produced when iron (Fe) reacts with oxygen (O_2): $4Fe(s) + 3O_2(g) \rightarrow 2Fe_2O_3(s)$.

How many grams of Fe_2O_3 are produced when 12.0 g of iron rusts? *(17.2 g)*

Answers

FIGURE 12.4 No; the given could be a product.

13. 2.03 g C_2H_2

14. 1.36 mol CaC_2

LESSON 12.2

Explain

Other Stoichiometric Calculations

START A CONVERSATION On the board, write equations for reactions in which the reactants are both gases or are a gas and a solid. Ask students how the reactants and products in each reaction would most likely be measured. Have students relate these measurements to the concept of a mole.

CHEMISTRY & YOU Manufacturers use balanced chemical equations to calculate the amount of product formed from a given quantity of reactants.

USE VISUALS Direct students to Figure 12.5, and walk them through it carefully. Although it looks complicated, it's really three steps: Take what you're given, and find a way to change it to moles. Then use a mole ratio from the balanced equation to get moles of the second substance. Finally find a way to convert the moles into the units that you need for the final answer.

Other Stoichiometric Calculations

What is the general procedure for solving a stoichiometric problem?

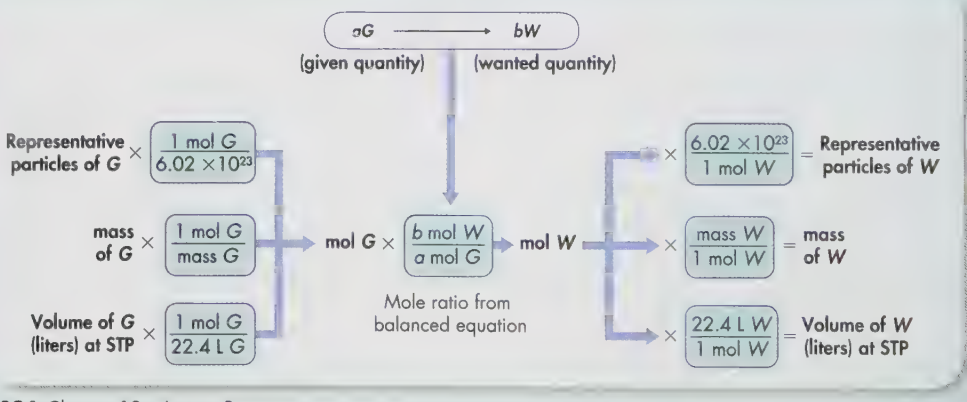
As you already know, you can obtain mole ratios from a balanced chemical equation. From the mole ratios, you can calculate any measurement unit that is related to the mole. The given quantity can be expressed in numbers of representative particles, units of mass, or volumes of gases at STP. The problems can include mass-volume, particle-mass, and volume-volume calculations. For example, you can use stoichiometry to relate volumes of reactants and products in the reaction shown in Figure 12.5. **In a typical stoichiometric problem, the given quantity is first converted to moles. Then, the mole ratio from the balanced equation is used to calculate the number of moles of the wanted substance. Finally, the moles are converted to any other unit of measurement related to the unit mole, as the problem requires.**

CHEMISTRY & YOU

Q: *How do you think air bag manufacturers know how to get the right amount of air in an inflated air bag?*

Thus far, you have learned how to use the relationship between moles and mass (1 mol = molar mass) in solving mass-mass, mass-mole, and mole-mass stoichiometric problems. The mole-mass relationship gives you two conversion factors.

$$\frac{1 \text{ mol}}{\text{molar mass}} \text{ and } \frac{\text{molar mass}}{1 \text{ mol}}$$



Recall from Chapter 10 that the mole can be related to other quantities as well. For example, 1 mol = 6.02×10^{23} representative particles, and 1 mol of a gas = 22.4 L at STP. These two relationships provide four more conversion factors that you can use in stoichiometric calculations.

$$\frac{1 \text{ mol}}{6.02 \times 10^{23} \text{ particles}} \text{ and } \frac{6.02 \times 10^{23} \text{ particles}}{1 \text{ mol}}$$

$$\frac{1 \text{ mol}}{22.4 \text{ L}} \text{ and } \frac{22.4 \text{ L}}{1 \text{ mol}}$$

Figure 12.5 summarizes the steps for a typical stoichiometric problem. Notice that the units of the given quantity will not necessarily be the same as the units of the wanted quantity. For example, given the mass of *G*, you might be asked to calculate the volume of *W* at STP.

Figure 12.5
Solving Stoichiometric Problems
With your knowledge of conversion factors and this problem-solving approach, you can solve a variety of stoichiometric problems.
Identify ***What conversion factor is used to convert moles to representative particles?***

UbD Check for Understanding

The Essential Question **How do you calculate amounts of reactants and products in a chemical reaction?**

Assess students' understanding of stoichiometry by showing students various equations for reactions in which the reactants are both gases or are a gas and a solid, such as $2Mg(s) + O_2(g) \rightarrow 2MgO(s)$. Have students create three note cards, one with the words *mass-volume*, one with the words *particle-mass*, and one with the words *volume-volume*. As you show students an equation, have them raise the card that names how they think the reactants and products in each reaction would most likely be measured.

ADJUST INSTRUCTION If students are still having difficulty deciding which ratios to use, review Figures 12.4 and 12.5 with them.

Sample Problem 12.5

Calculating Molecules of a Product

How many molecules of oxygen are produced when 29.2 g of water is decomposed by electrolysis according to this balanced equation?

$$2H_2O(l) \xrightarrow{\text{electricity}} 2H_2(g) + O_2(g)$$

1 Analyze **List the knowns and the unknown.** The following calculations need to be performed:

g H_2O ⟶ mol H_2O ⟶ mol O_2 ⟶ molecules O_2

The appropriate mole ratio relating mol O_2 to mol H_2O from the balanced equation is 1 mole O_2/2 mol H_2O.

KNOWNS

mass of water = 29.2 g H_2O
1 mol O_2/2 mol H_2O (from balanced equation)
1 mol H_2O = 18.0 g H_2O (molar mass)
1 mol O_2 = 6.02×10^{23} molecules O_2

UNKNOWN

molecules of oxygen = ? molecules O_2

2 Calculate **Solve for the unknown.**

Start with the given quantity, and convert from mass to moles.

$$29.2\ \text{g}\ H_2O \times \frac{1\ \text{mol}\ H_2}{18.0\ \text{g}\ H_2O}$$

Remember to start your calculations with the given quantity, even if the given quantity is a product in the reaction

Then, convert from moles of reactant to moles of product.

$$29.2\ \text{g}\ H_2O \times \frac{1\ \text{mol}\ H_2}{18.0\ \text{g}\ H_2O} \times \frac{1\ \text{mol}\ O_2}{2\ \text{mol}\ H_2O}$$

Finish by converting from moles to molecules.

$$29.2\ \text{g}\ H_2O \times \frac{1\ \text{mol}\ H_2}{18.0\ \text{g}\ H_2O} \times \frac{1\ \text{mol}\ O_2}{2\ \text{mol}\ H_2O} \times \frac{6.02 \times 10^{23}\ \text{molecules}\ O_2}{1\ \text{mol}\ O_2}$$

Given quantity | Change to moles | Mole ratio | Change to molecules

$$= 4.88 \times 10^{23}\ \text{molecules}\ O_2$$

3 Evaluate **Does the result make sense?** The given mass of water should produce a little less than 1 mol of oxygen, or a little less than Avogadro's number of molecules. The answer should have three significant figures.

15. How many molecules of oxygen are produced by the decomposition of 6.54 g of potassium chlorate ($KClO_3$)?
